The engraving shows the construction of the machine so plainly that but little explanation is needed. On the crank shaft is a pinion engaging with a gear on a shaft having, at its inner end, a beveled pinion meshing with a beveled gear formed in the periphery of the revolving head. This head is formed with suitable guides for the tool carriage, which is fed to the work by means of the hand wheel shown. It will be observed that this train of gears provides ample power to enable the tool to take a deep cut.

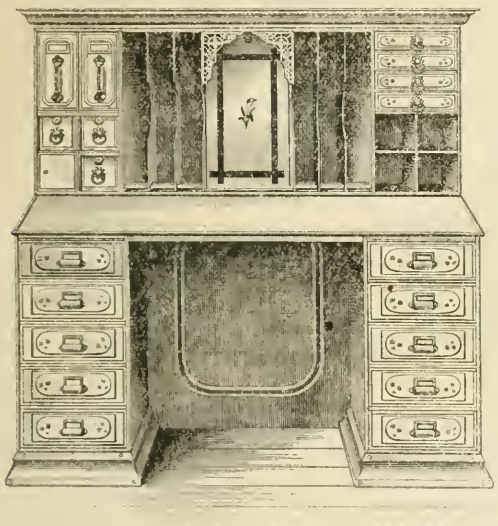
According to *Industries*, alcohol has been found efficacious as a solvent, in place of chloride of calcium solution, of obstructions in gas pipes. The burner is unscrewed and a small quantity of methylated spirit poured down the pipe.

In 1892 there were sent from the post offices of the United States to England 10,057,640 letters, to Germany 5,858,040 letters and to France 1,884,040 letters.

Sheet-Metal Furniture.

The possibilities of sheet metal in the line of furniture are considerably greater than is popularly supposed. That this material can be adapted with effect and utility to the construction of many articles of use and convenience hitherto made almost exclusively of wood was proved recently by the receipt of a photograph and description of a handsome office desk made throughout of sheet steel. The desk, which is shown in the accompanying illustration, is the work of Christian D. Then, 589 North Clinton street, Rochester, N. Y., who informs us that he has made a number of similar articles of furniture. This specimen is constructed of No. 16 to No. 24 gauge sheet metal, riveted together firmly, the rivets being beveled and countersunk. The metal is either japanned or bronzed, and the whole piece handsomely finished and decorated.

A notable feature of this work, to which the maker calls special attention, is that



Sheet-Metal Furniture.—Steel Office Desk.

the desk shown is fitted with outer panels, which form an air chamber, rendering the object nearly fire proof. Comparative indestructibility by fire is a recommendation which would certainly be held by steel furniture, and it is a feature which deserves attention. Mr. Then states, moreover, that he is prepared to furnish, not only steel desks, but any other description of work in a similar line that can be made in wood. A rolled-top desk of steel, which is said to be equally effective, has been lately made by him.

These novelties suggest a new line of usefulness for sheet metal which might be followed up with advantage. We frequently see light metal chairs and tables, and, of course, iron has long been used for bedsteads, camp washstands and other specialties.

The theory has been advanced by an old mariner that the White Star freight steamer "Naronic," now given up as lost, "turned turtle" while battering with heavy seas and went to the bottom. Her commander is reported as having said that "she was the deepest rolling ship he had ever seen." Besides, she had a heavy deck-load, including a 40-ton locomotive.

The Recent Labor Decisions.

There have come in quick succession two decisions, says *The Iron Age*, emanating from United States courts on matters relating to the labor question, which give judicial dignity to doctrines hitherto held only by a few. It is not only the railroad magnates and managers who have believed that Vanderbilt's famous dictum, "the public be d——d," pretty well represented a correct attitude. The men have generally acted with even greater disregard of the third interested party, from whom charters and special privileges spring. The managers have been made to feel that the enjoyment of rights is coupled with responsibilities and duties. The recent decisions alluded to are a departure, in that they impose upon labor obligations which have not been generally recognized as yet.

Judge Ricks of Toledo addressed the engineers and firemen who had declined to handle boycotted cars in the following terms, which cover his conception of the duty of railroad employees:

You are engaged in a service of public character, and the public is not only interested in the manner in which you perform your duties while you continue in that service, but is quite as much interested in the time and circumstances under which you quit that employment. You can't always choose your own time and place for terminating the relations. If you were permitted to do so you might quit your work at a time and place and under circumstances which would involve irreparable damage to your employer and jeopardize the lives of the traveling public. Your employers owe a high duty to the public, which they are compelled to perform under severe penalty, and they have in turn a higher claim upon you and your services than that due from the ordinary employee. This court does not assume the power or compel you to continue your service to your employers against your will, but it does undertake to compel you to perform your whole duty while such relations continue, and does further claim, for the purposes of ascertaining whether its orders have been violated, the right to determine when your relation to your employer legally terminated and when your obligations to observe this order cease. It may, in the meantime, be important for you to reflect and consider whether you can safely proceed to continue in your employer's service with the purpose to quit at a moment when some duty may be required of you which is in violation of some supposed promise or obligation you owe another not your employers. That time for leaving your post of duty might come under circumstances when you would by such act unintentionally imperil the safety and lives intrusted to your employer and do his business vast and irreparable damage. It might, too, unintentionally involve you in conflict with the court because of obstructing its process and interfering with its mandates. I therefore suggest to you and all others who are in similar employment that there ought not to be any strained construction made of the provisions of the court's order. The one safe way to obviate trouble is to quit the service of your employer. If you continue that employment this court will expect you to do your full duty to your employer and to the public, and to observe the orders which have been made in this case.

Far reaching as the establishment of such a doctrine by the highest courts in the land would be, an even more sweeping dictum comes from Judge E. C. Billings of the United States Circuit Court at New Orleans. In November last the employees of the warehousemen of New Orleans went out on a strike. The union men were called out and resisted the effort of their employers to engage other men by intimidation, and in some instances by violence. Proceedings were begun by the United States against the labor organizations involved, but before the suit was argued the strike ended. Although the latter event occurred four months ago, Judge Billings deemed it his duty to pass on the questions involved. After a recital of the facts, the decision concludes:

The question is, "Do these facts establish a case within the statue?" It seems to me this question is tantamount to the question, "Could there be a case under the statute?" It is conceded that the labor organizations were at the outset lawful. But when lawful forces are put into unlawful channels—*i. e.*, when lawful associations take on unlawful purposes and do unlawful acts the associations themselves become unlawful. The evil as well as the unlawfulness of the act of the defendant consists in this, that until certain demands of theirs were complied with they sought to prevent, and did prevent, everybody from moving the commerce of the city. It was the successful effort of the combination of the defendants to intimidate and overawe others who were at work in conducting or carrying on the commerce of the country in which the court finds their error and their violation of the statute. One of the intended results of their combined action was the forced stagnation of all the commerce which flowed through New Orleans. This intent and combined action are none the less unlawful because they included in their scope the paralysis of all other business within the city as well.

For these reasons I think the injunction should issue.

It will be observed that the broad ground is taken that a combination in restraint of commerce is unlawful, and that the organizations themselves are responsible for acts committed with the end in view. Here again the rights of the community are pushed forward. What many have been accustomed to regard as merely a private struggle between the two contending parties is influenced by the rights of the general public.

THE LETTER BOX.

Forming Wash Boilers.

From R. S. T., *Coal Creek, Col.*—In reply to "O. J. B.," Troy, Ind., whose inquiry appeared in *The Metal Worker* of March 11, would say that I have used a wooden roller 3 feet long and 10 inches in diameter at one end and 4 inches at the other, with a pin in each end about 6 inches long, the pins resting on two wooden supports. The manner of using it is to sit straddle of the roll and bend the tin over it by hand. I find that I can form up wash boilers quicker by this means than by using the forming rolls. As the wooden roll is tapered it can be used to form any size of boiler without the use of a mallet, except the two ends, which I start over the mandrel with the mallet.

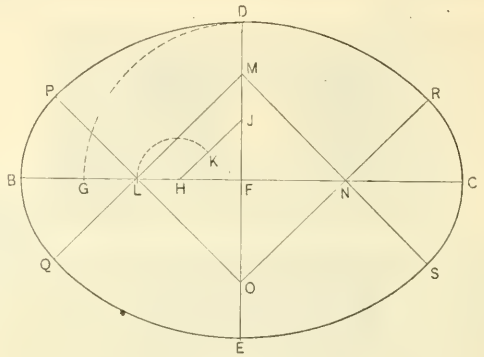
From F. J. F., *Coon Rapids, Pa.*—In reply to "O. J. B.," Troy, Ind., would say that it is rather hard to figure out what he means by a boiler former; but suppose he means an oval-shaped block the shape of the boiler, which may be placed inside the body after it is roughly formed up, and a mallet, used to form the top or wire on the block. There are several ways of forming up an oval wash boiler. Some use rollers, and after adjusting them so that the body will roll straight, the rollers are screwed up five half turns for the oval ends. This, however, makes it too much work, as it is necessary to turn the thumb screws up and down for the center of the body. I once knew a tinner who used 8 or 9 inch stove kettles to form his boilers on, placing his kettles on the mandrel. My way of doing the work is to take some heavy galvanized strips, such as come bound around galvanized iron. One strip should be the length of the half round end, and the other half the length of the first strip. The two strips are then taken and formed to the desired shape of the boiler, the ends being hammered or drawn out so as not to leave a ridge where they start in on the body and where they leave off. Then screw the upper roller as far up as it will go, and after adjusting the back roller to the proper place, form up the boiler to the desired shape. I start the body in with short strip on top of the wire. As they pass through and the short strip falls out you have the half of one end formed up, and the body will pass through freely without moving the rollers. The center and the other end are done in a similar way.

From ON THE ROAD, *New York.*—In the article published in *The Metal Worker* of March 25, page 47, on the subject of wash boilers, a slight error occurs which I desire to correct. Where it says "cut another piece of band iron just as long as the first piece," I should have said, "cut another piece of band iron just half as long as the first piece." This, I think, will make the matter perfectly clear.

An Elliptical Arch.

From SUBSCRIBER, *Paterson, N. J.*—I would like to be informed of a method for describing an elliptical arch.

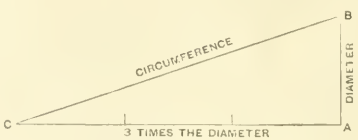
Answer.—A convenient method for describing an ellipse by using two sets of centers is shown in the accompanying engraving. The figure once obtained, either half, as E B D or B D C, can be used for the arch. Let B C represent the length of the figure and D E the width. B C and D E are drawn at right angles to each other, intersecting at their middle points at F. From F on F B set off the distance F D, as shown by F G. Take the distance B G and set off from F, as shown by F H. F J. Then draw J H and bisect J H in K. Set off H K on H B, as indicated by H L. F L is to be set off on F D, F C and F E, as shown at M, N and O. From M, draw M L Q and M N S, extending them indefinitely, and in a similar manner draw O L P and O N R. With L as center and L B as radius, strike the arc Q B P, cutting L Q and L P, as shown. With the same radius, and with N as center, strike the arc R C S. With O as center and O D as radius, strike the arc P D R, cutting O P and O R. From M as center, and with the same radius, strike the arc Q E S, thus completing the figure.



Method of Drawing an Elliptical Arch.

How to Find the Circumference of a Circle.

From W. P. R., *Shenandoah, Pa.*—I notice in *The Metal Worker* of February 25 a letter from "C. W. F.," giving a method of finding the circumference of a circle. I will try to explain my way, which, I think, is the simplest I have ever seen. Take an ordinary square, which almost every tinner has in his shop; measure from one corner the diameter one way and three times the other way, and the diagonal distance between the points will be the length of the circumference. I inclose diagram illustrating my method. Assuming that the circle is 5 inches in diameter, lay off 5 inches on the line A B and 15 on the line A C. Then the distance C B would be the circumference of the circle.



How to Find the Circumference of a Circle.

Stove Pipe for Natural Gas.

From A. H., *Shelbyville, Ind.*—I have a long stove pipe made of iron and used where natural gas is burned. The trouble is that the pipe sweats on the inside and soon rusts out. I would like to know how to keep the pipe from sweating or what kind of material would last under the circumstances?

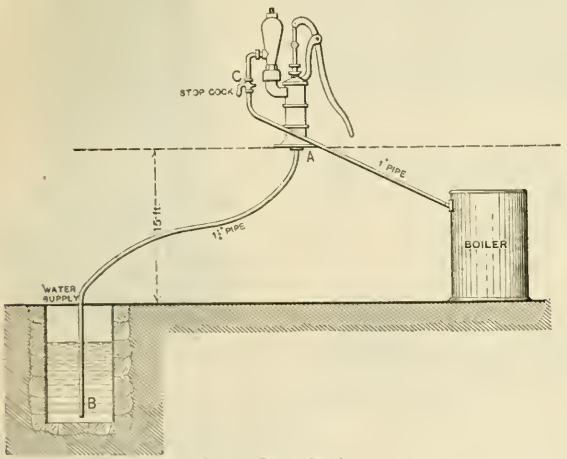
Note.—In burning natural gas water is produced, and in a long smoke pipe the cooling action would condense this water and give rise to the trouble complained of. We presume our correspondent's smoke pipe is of black iron, and if so it is no wonder it rusts out rapidly. Better results would be obtained with galvanized iron or bright tin plate. If our correspondent is willing to go to some little expense, however, we would suggest the use of copper, which will last longer. It must be borne in mind, however, that the water and the heat combined, together with the impurities that are likely to collect in the water, will have a strong corrosive effect; but we think copper would probably give better results than any other common materials. Another plan which might be successful would be to cover the smoke pipe and thus prevent the loss of heat. By this means the water

would be carried off in the form of vapor in the chimney instead of being condensed in the pipe.

Faulty Pump Suction.

From L. R., *Warren, Pa.*—I wish you would explain how to improve the working of a pump that I had some trouble with. A short time ago I set a suction and force pump for the purpose of filling a hot-water heater. The trouble is it don't seem to have any suction. It draws water 15 feet and it works all right when the water is once got, but it takes a long time to bring it. I have new leathered it all around, but its suction is no good. The inclosed sketch will give you an idea of its construction.

Answer.—Our correspondent sends us a sketch, as shown, of the general arrangement of this job, the position of the cistern, pump and the heater boiler, also the pipes connecting these, being as the



Faulty Pump Suction.

sketch and his rather meager description indicate, we are inclined to ascribe the cause of the peculiar action of the pump either to some slight defect in the casting of the pump itself or to a defective leather packing of the plunger. A pump to work satisfactorily must be perfect in casting, the valves must all work properly and the packing must fit snugly in the suction chamber. Then the pipe to the supply cistern must be perfectly air tight from the pump at A to the other end at B. The least amount of leakage, be it ever so minute, often seriously interferes with the proper working. Care must be taken not to have the end B too near the bottom of the cistern. It may be in this case that the bottom of the cistern is covered with sediment. We recall a case somewhat similar to this one, where the opening at B was too far down in a cistern. Every time the attempt was made to pump water it took some time before the water would commence to run. This was owing to the mass of rubbish and mud which had been allowed to accumulate at the bottom of the cistern. After the cistern had been cleaned out and the pipe shortened somewhat, no further trouble was experienced.

Soldering Aluminum

From R. M. W., *Pittsburgh, Pa.*—Please tell me through the columns of *The Metal Worker* how to solder or braze aluminum. What kind of solder is used, and what kind of flux?

Answer.—It is a difficult matter to solder aluminum satisfactorily, and while there are many compositions used for the purpose, and a great deal of this sort of work done, there still appears to be much room for improvement. In the exhaustive work by J. W. Richards on aluminum, or, as he more appropriately terms it, "aluminium," there are several pages given up to the subject of soldering, at the end of which is the following sentence that is worthy of quotation: "I am quite aware of the criticism which the above information about aluminum solders will meet; that much more satisfactory alloys have been discovered and are now used; and this is possibly the case. But it must be remembered that a metal worker who, by searching patiently, discovers such an improvement, considers that his reward is found in keeping to himself the monopoly of its use, and that to obtain these trade secrets is, in most cases, almost impossible, especially since the more valuable they are the more carefully are they guarded." Mr. Richards gives a variety of solders in his work, quoting them from various sources. Also some description is given of the method of preparing the solders. We quote the following as one of the examples: "O. W. Thowless has patented the following solder for aluminum, and the method of applying it. The solder is composed of:

Tin, 55 parts.
Zinc, 23 parts.
Silver, 5 parts.
Aluminum, 2 parts.

"The silver and aluminum are first melted together, the tin added, and lastly the zinc. The metal surfaces to be united are immersed in dilute caustic alkali or a cyanide solution, washed and dried. They are then held over a spirit lamp, coated with the solder and clamped together, small pieces of the alloy being placed around the joints. The whole is then heated to the melting point of the solder, and any excess of it removed. No flux is used."

Adjustable Pot Covers.

From T. E. S., *Bay City, Mich.*—I wish to inquire through the columns of *The Metal Worker* who manufactures a pot cover so arranged as to expand and contract to fit dishes. It is made of tin, with a wire spring from the top to the edge.

Note.—The cover that our correspondent is looking for was, we think, brought out some five or six years ago, and sold in large quantities through the West, but we do not think it proved a commercial success, as we have not seen reference to it lately. If any other correspondent can furnish information about it we will be glad to get it.

Expansion of Gasoline.

From J. G., *Philadelphia.*—If I was to stand a steam drum before the sun and put 60 gallons of gasoline into it—tank being ¼ inch iron and 2-inch cast flat heads, diameter 24 inches, length 6 feet—would it be safe without a safety valve? Temperature is 120° F. at times in July. What pressure would it be likely to have on it caused by the expansion of the gasoline? Would it be advisable to locate a safety valve on it?

Answer.—As gasoline vaporizes, according to quality, at from 75° F. to 120° F., it is evident that, under the conditions described by our correspondent, the substance would be liable to expand to a dangerous extent, whatever the particular quality placed in the tank might be. The limit of pressure caused by expansion of gasoline is an unknown quantity. Practically it is infinite, and the safety of a vessel containing it under stress of heat would be merely in proportion to its stability. It would, therefore, be necessary in this case to place a safety valve on the tank. The best advice we could give our correspondent would be to so cover the drum as to minimize the heat that would strike it; or, if possible, to protect it from the direct rays of the sun; as, even with a safety valve, gas might be generated to a highly dangerous degree under excessive heat.

The builders' trial trip of the armored cruiser "New York" took place last week. Her engines were put to the most severe tests, with remarkable results. Steaming twice over a course from the Five Fathom Bank Lightship to the Northeast End Lightship, a distance of 9.88 knots, in 12 fathoms of water, an average of 19.95 knots per hour was made under ordinary draft. A maximum speed of 20.47 knots was made in 40 fathoms of water under a forced draft of 1 inch pressure, being ½ knot more than the guaranteed speed. It was not necessary to stop the engines for any adjustment and not a journal was heated.

The Supreme Court has affirmed the right of Philadelphia to tax telegraph poles erected in that city.

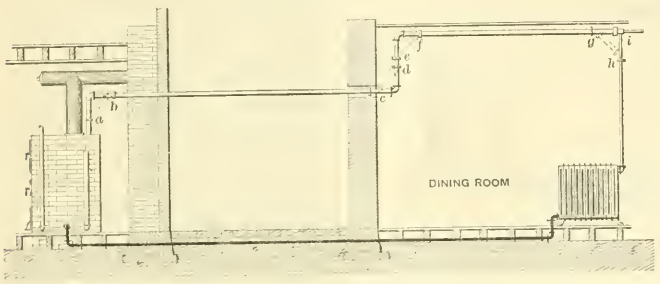
The "monkey-wrench" is not so named because it is a handy thing to monkey with, or for any kindred reason. "Monkey" is not, in fact, its proper name at all, but "Moncky," after its inventor, Charles Moncky, who sold his patent for $7,000.

STEAM AND HOT WATER.

Radiator on Boiler Level.

From M. E. R., *Nashville, Tenn.*—I inclose herewith sketch showing the location of hot-water boiler, and also where I would like to place the radiator, which is in a dining room, the floor of which is on a level with the boiler-room floor. I would like to know if this can be done; also, what size of pipe will be required for the flow?

Answer.—Jobs of this kind are often made to work satisfactorily; but also quite often they give trouble. Radiators for hot-water heating placed on a level with the boiler should have the easiest possible flow through supply and return pipes, and these should be either independent of all other runs, or, better still,

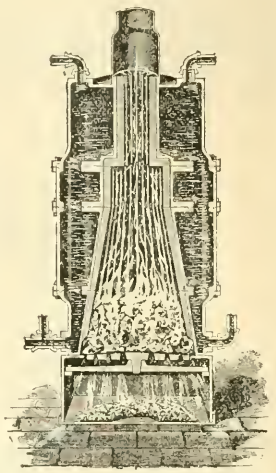


Radiator on Boiler Level.

their supply pipes should be extensions of returns from radiators placed at higher elevations, with a short pass-by run connecting the supply pipe, from a point a little before it enters the radiator, with the outflow pipe from the radiator. The radiator in this arrangement should have the usual supply valve, and the pass-by should have a valve in it also. This arrangement permits the radiator to be shut off when desired without stopping circulation in the higher radiators from which the water flows to supply it. Of course, when this arrangement is used the radiator will need to have a little more surface than is required when it takes its supply at a higher temperature, directly and independently from the boiler. The piping shown in our correspondent's diagram should be not less than 1¼-inch for most successful working, and should have 45° fittings at *a b c d e f g h*, as shown by dotted lines, instead of the right-angled ells. Or, better still, if a fitter having the skill to do it is available, the pipe might be bent, with easy bends, to avoid so many fittings as would otherwise be necessary. The continued run at *i*, indicated in the diagram, will interfere with the working of the radiator below it, and ought to be avoided. If another radiator, or radiators, above it are to be supplied, they should have an independent supply pipe. The supply pipe, in its horizontal parts, should have an upward incline of 1 inch in 10 feet till the point *g* is reached. The reason for recommending so large pipe is that the resistance to circulation will, in any case, be large in proportion to the head produced by difference of temperature in vertical pipes of so little hight above the boiler as occurs in jobs of this kind, and the resistance is lessened by the use of pipes of liberal size. If the directions given are followed we think our correspondent will succeed in obtaining a moderately good circulation; but, as has been said, more or less uncertainty attaches to an arrangement of this kind; while if the first method described be followed, there should be certainty of success, provided the work be done in accordance with good practice in all other respects.

The Caldwell Heating Boiler.

The accompanying illustrations show a vertical section, as well as a larger horizontal sectional view, of the Caldwell heating boiler, made for both hot water and steam, which is being manufactured by the Goulds & Caldwell Company, 22 and 24 North Canal street, Chicago, Ill. The general appearance of the boiler is shown in the vertical section, Fig. 1, from which it will be seen that it consists of horizontal sections, bolted together on the outside, and giving annular water spaces about the fire pot. The principal feature of this boiler to which the manufacturers direct attention, are the vertical ribs placed around the fire pot, as shown in Fig. 1. These ribs, it is pointed out, furnish air passages by which air is supplied at the sides of the fire, producing much more perfect combustion. At the same time, on the upper part of the coal magazine, above the fire pot, they furnish an absorbing surface, for facilitating the transfer of heat to the water. The air taken in these passages, it is said, besides promoting the combustion on the grate, also serves to burn the unconsumed gases in the fire pot and prevent smoke. Even with the use of soft coal, it is stated that no smoke is given off, except just when the fire is started. The boilers are made either surface burning or self feeding, as desired. The sections are connected by a tongue and



The Caldwell Heating Boiler.—Fig. 1.—Vertical Section through Boiler.

groove joint, bolted together with a special gasket placed in the bottom of the groove, so as to make a very tight and strong joint. Fig. 2, which is an enlarged horizontal

Fig. 2.—Horizontal Section through Boiler.

section, shows very clearly the arrangement of the ribs about the fire pot and the air spaces that they form.

Destruction of Pipes by Condensed Steam.

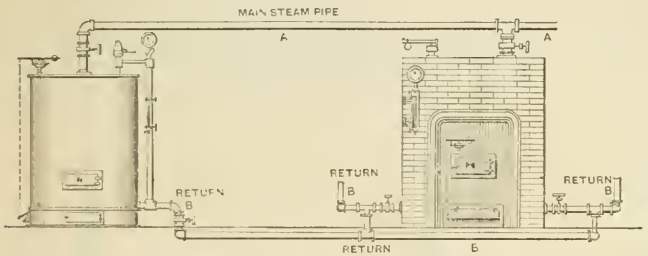
From J. T., *Brooklyn, N. Y.*—In reply to "E. S. & S.," whose letter appears in *The Metal Worker* of March 18, would say that I have had some experience with corroding pipes. I have seen the nipples in the radiators honeycombed their entire length, and in bad spots would corrode through in a single season. This always occurred in plants where exhaust steam was never used for heating. On the other

hand, I have never heard of this trouble occurring in plants where the exhaust was utilized, and attribute the non-corrosion in such cases to the surplus oil from the engines, forming a thin coating on the internal surface of the pipe. I would suggest that "E. S. & S." connect the exhaust with the heating mains, if it is practicable. If any one has experienced the above trouble, where the exhaust steam was used, I would be glad to hear from him.

Brick-Set and Portable Boiler Combination.

From INTERSTATE, *Philadelphia.*—Some time since we furnished a brick-set low-pressure boiler to heat a customer's house. Subsequently he built a large addition to the house, rendering the boiler inadequate for his needs. We then put in a portable boiler, about one-third the capacity of the first, to help out number one, and connected the steam and return pipes, as shown in the sketch. We found, however, that the large boiler draws the water from the small one, so that no water shows in the gauge glass of the latter. The gauge glasses are on a level. Can you suggest a cure?

Answer.—Unless the one or the other boiler foams or primes, or both, which our correspondent would have probably discovered, there appear but two solutions to the difficulty he is experiencing. With the way in which the boilers are connected in the sketch, when both boilers are steaming, in order that steam may issue from the small boiler through the main A, it must have a pressure somewhat exceeding that of the large boiler. This excess of pressure must be enough to overcome the pressure of the large boiler, which is exerted from the outlet in opposite directions after reaching the first tee on the nipple that rises from the boiler. Any excess of pressure in the smaller boiler will cause water to back through the return connections into the larger boiler, and this will continue till the increased elevation of water in the larger boiler balances the excess of pressure. The remedy we would suggest is to disconnect the run between the two boilers, as now arranged, and connect it at some point of the main A to the right of the outlet of the larger boiler, making the new connection into the main at right angles, and making the run as direct and easy as possible from the smaller boiler to the point of connection. If our correspondent adopts this plan, we shall be glad to hear how it operates. Of course, if priming or foaming exists, this may create a resistance in the circulation that is adequate to account for the difficulty; and this would need to be cured before two boilers connected as described could be expected to work harmoniously together. It may be, however, that resistance to circulation arises from an insufficient number of reliefs connecting the steam main and risers with the return main; and, before changing the run, our correspondent might try the effect of a 1¼-inch relief pipe connecting the steam pipe with the return connection, between the two boilers and between the two valves in the return, at a point as near to the return valve of the larger boiler as convenient.



Brick-Set and Portable Boiler Combination.

HEATING NOTES.

THE NASHVILLE MACHINE COMPANY, Nashville, Tenn., are sole manufacturers for the South of the G. & J. R. Bolton improved hot-water heater, they having the exclusive right to manufacture and sell in Delaware, Maryland, West Virginia, Virginia, South and North Carolina, Georgia, Alabama, Florida, Mississippi, Louisiana, Texas, Tennessee, Indiana, Missouri and Kentucky. Since they introduced this department in their business, last June, the company have been over a great deal of their territory and established agencies in a majority of the large cities, except the eastern portion, and are looking forward to a large trade this season. The Nashville Machine Company, besides manufacturing the G. & J. R. Bolton heater, are contractors for steam, electric and hydraulic elevators. They also carry a full supply of pipe fittings, valves, mill and water-works supplies.

RUSSELL WHEELER & SON, Utica, N. Y., send out advertising circulars, together with a letter, addressed to the trade. One of the circulars is a folder, giving full descriptions, with illustrations, of the Palace King hot-water boilers, together with tables of sizes, prices, ratings, &c. The larger publication is a square pamphlet, neatly bound and printed and entitled "A Talk on Hot-Water Heating." The publishers say it is their desire in this little book to answer the questions that are often asked in their every-day business by intending purchasers of heating plants. The book, or rather the earlier part of it, is in the form of a catechism, in which all the usual questions are asked and answered in a simple, straighforward way. The rest of the pamphlet is given up to a comparison of the steam and hot-water heating systems, and at the end is a full description of the Palace King apparatus. In the circular letter accompanying these pamphlets Messrs. Wheeler & Son say: "We have not taken another fellow's catalogue and carefully read up the ratings of his boilers, and, because he said a square foot of grate surface would carry so much of radiation, said and catalogued that ours would do the same." They intimate that their ratings are low and founded on practical experience.

FOSKETT & BISHOP, New Haven, Conn., have been succeeded by the Foskett & Bishop Company, incorporated under the laws of the State of Connecticut. The amount of capital stock is given as $60,000, and is held by William A. Foskett, Noble P. Bishop, Ebenezer B. Beecher, Charles E. Rounds and James R. Bolton.

IN THE CITY OF SCHENECTADY, N. Y., there was recently built a new hospital in memory of John Ellis. The building is 60 feet square, made of brick with terra cotta trimmings, and three stories in hight. It is excellently arranged for hospital purposes, and much care has been given to the heating and sanitary arrangements, which work was done by J. V. Vrooman's Sons of Schenectady. The heat is furnished by a 35 horse-power horizontal tubular boiler, which is set in a pan of boiler iron to prevent any danger of water entering the ash pit. Ample provision is made for ventilating the wards by means of registers under the beds, connected with flues carrying the foul air to ventilating chimneys. In the top of the two ventilating chimneys are 30-inch exhaust fans run by electric motors set in the basement. The heating is done by the indirect method, the radiators being distributed about the cellar inclosed in galvanized iron boxes. The air flues are so arranged that fresh air can be brought into the wards without first passing through the radiators, or the supply can be made a mixture of cold and warmed air. In the main building the heating is by direct radiators set in the rooms and halls. The total surface is 34 direct radiators and 19 indirect radiators, with a heating surface of 2000 square feet. Much care has been given to the plumbing of the building, all the work being exposed so as to insure cleanliness. The plan followed was in conformity with the New York City plumbing regulations, and we understand that the new regulations adopted in Schenectady are largely based upon the plumbing rules of this city.

AMONG the prominent buildings in Chicago that have recently been provided with steam heating and power plants by the Theo. Jacobs Company, 72-74 Market street, Chicago, are: Lees Building, Fifth avenue, 12 stories; Security Building, Fifth avenue and Lake street, 14 stories; Ogden Building, Clark and Lake streets, eight stories; Unity Building, Dearborn street, 16 stories. Plants are being put in Wachusett Building, Van Buren and Dearborn streets, 17 stories; Old Colony Building, Dearborn and Van Buren streets, 17 stories; Park Gate Hotel, Stony Island avenue and Sixty-third street. Also in the following apartment buildings: Pruyn, Enders, Hyde, Hayden and many others.

GEO. D. HOFFMAN, 82 Lake street, Chicago, is to supply the steam-heating plants for the following buildings in Chicago: Two Hoffman locomotive boilers and 3500 feet of radiation for the six apartment houses of C. W. Pardridge, Forty sixth street and Lake avenue; for the Delaware Building, 1435-1439 Wabash avenue, two horizontal tubular boilers will be used to furnish steam for one 80 horse-power engine, one 40 horse power Weston automatic engine and 8500 feet of radiation; for the E. H. Stead Building on North Clark street one Bronson steel boiler and 1400 feet of radiation. The Perfection radiators, manufactured by the American Radiator Company, are to be used in the above buildings.

Justice Bremer of the United States Supreme Court, in an address delivered in Washington last week, expressed himself strongly in disapproval of discrimination against the Chinese while other races are privileged with the rights of citizenship.

PLUMBING AND GAS FITTING.

The New York Trade Schools.

The twelfth season of the New York Trade Schools will be brought to a close on Friday evening next, April 7, when the presentation of certificates to those students who have graduated during the term will take place. The closing exercises will be held in the new auditorium, at the school buildings, First avenue, between Sixty-seventh and Sixty-eighth streets, under the presidency of William E. Dodge, one of the board of trustees of the institution. The following is an outline of the programme that is proposed to be followed on the occasion, subject to possible change :

7 to 8 p.m.—Inspection of the work done by the classes during the past term.

8 p.m.—Address by Guy Culzin, president of the General Society of Mechanics and Tradesmen, New York.

Address by Henry G. Gabay, president of the Master Plumbers' Association.

Address by T. C. Johansmeyer, ex-president of the Master Painters and Decorators' Association.

Presentation of certificates.

Valedictory by Hamilton E. Claflin, of the day plumbing class.

Address by J. Stanley Thomas.

Address by the chairman, William E. Dodge.

There will probably also be other features of interest in the proceedings, and a large attendance of students and friends of the schools is anticipated.

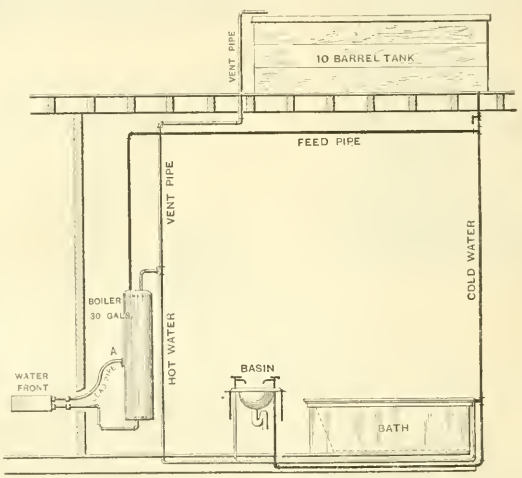
Great regret is felt that Colonel Anchmuty will not be able to be present at this gathering, having recently undergone a severe surgical operation, from which, we are happy to state, he is recovering satisfactorily, but it will be some weeks before he is able to undertake any very active work.

The past term of the New York Trade School is reported to have yielded excellent results. Greater interest than ever appears to have been evinced by the students in the various branches of instruction, and their progress in proficiency has been marked. Gratifying proof of the skill of the youths trained this season is about to be forwarded to Chicago in the shape of a striking exhibit for the World's Fair composed of specimens of work done by the students in the various classes. Unfortunately the limited space allotted to the schools precludes the sending of all the examples of work originally intended to be displayed ; but enough will be shown to demonstrate clearly the value of the work now being done in this admirable institution. The plumbing section of the exhibit embraces very excellent examples of the work of students in that class; and a worthy showing of the work of other trades, particularly of the carpenters' and blacksmiths', is made in the collection.

Vent Pipes Near Windows.

From T. M. R., *Illinois.*—Would it be considered in accordance with sanitary requirements to run a vent pipe from a water closet through the roof on the one-story part of a house, and have it terminate at the level of the second story windows in the second-story part of the dwelling?

Answer.—The New York plumbing code does not permit an opening from the house, soil and waste pipe system at a less distance from a window than 30 feet. In such a case as our correspondent mentions, under the rules of the Health Department, formerly in force, the vent pipe after passing through the roof in its enlarged caliber, was branched over to the rear wall of main building and carried up in the usual manner above the roof along with the soil pipe. Now, however, under the Building Department regulations, only one pipe is carried up, the vent pipe being branched into the soil pipe, above the highest fixture. The soil pipe, however, is carried to the main building, as it is bad and unsanitary practice to terminate a vertical line of soil or waste pipe above an extension roof and on a level with windows, either in the house or belonging to adjacent buildings.



A Noisy Range Boiler.

A Noisy Range Boiler.

From F. H. & N., *Dundee, N. Y.*—We address you for information in water-heating arrangement, as shown in the accompanying diagram. The trouble is that there is a rumbling and snapping at A in the return pipe from boiler to water front. We first had $\frac{3}{4}$-inch iron pipe where the 1-inch lead pipe now is. We think the 1-inch lead pipe helps the trouble a little, but still it rumbles and snaps continually. We have examined every pipe about the boiler and water front to see that none were screwed in too far. We would place the boiler further away from the range, but cannot do so, as there is no place to put it in.

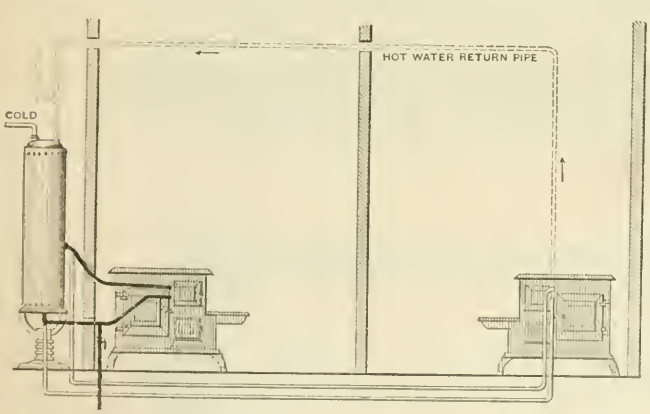
Note.—As our correspondents' sketch shows, there is apparently no trouble with the pipe. It would, however, be better for the cold-water pipe between the water front and boiler to run on an easy curve, instead of the sharp bend shown in the sketch. It is possible that this construction, due to the sharp bends, may retard the water sufficient to permit the formation of steam, and that being expelled from the water front and condensing as it meets the cold water leaving the boiler, gives rise to the rumbling and cracking noise complained of. We would suggest that while this may increase the trouble, not unlikely the real cause is due to the too large exposure of the water front to the fire. Our correspondents might try the experiment of cutting off some of the water back by means of fire brick placed in front of it. There would be no particular advantage in placing the boiler further away from the water front ; the only difference would be that there would be the chance of radiation from the connecting pipes, but this would not have any appreciable effect.

Change of Range Boiler Connections.

From T. V. L., *Holland, Mich.*—One of my customers has a kitchen boiler and stove, with heating coil, set up in the usual position, with flow and return pipes fixed in orthodox fashion. The boiler stands in bath room, which is separated from stove by a partition, but the water is heated and circulates satisfactorily. The owner, however, desires turning the room in which the stove stands to some other purpose, and contemplates moving the stove into another room 24 feet away from the range boiler. The difficulty is in providing for the hot-water circulation pipe, which it is suggested should be brought down from water back and carried, together with the cold-water supply pipe, under the floor for 24 feet, and then connected in the usual way at side opening in boiler. I do not think it will work satisfactorily ; but as the owner desires the job, of which I inclose a

sketch, done in that way, I would like an opinion from *The Metal Worker*.

Answer.—The sketch submitted by our correspondent, as indicating the proposed change, shows the pipes carried under the floor from boiler to stove and return. Such an arrangement would be defective, as regards the hot-water return pipe, which would be trapped, and would not work satisfactorily, while the cold water may be carried under the floor, as shown. The better plan, as regards the hot-water pipe, would be to carry it upward and across the intervening space along the ceiling, finally connecting it at top of boiler. By this means a proper circulation will be established, and no trapping of the hot-water pipe occurs, such as would be the case if run under the floor. The natural tendency of water when heated is to rise, and if this action is reversed, trouble, dissatisfaction and failure to accomplish the desired result will necessarily follow. The diagram which we herewith present gives an intelligent view of the situation. The solid lines show the present or existing method, the stove and boiler in close proximity to each other, and the flow and return pipes discharging their functions properly. The double lines illustrate the hot and cold water pipe arrangement, with the stove removed 24 feet from boiler, as desired by the owner of the building. The dotted lines show the direction which we suggest as the proper one for the hot-

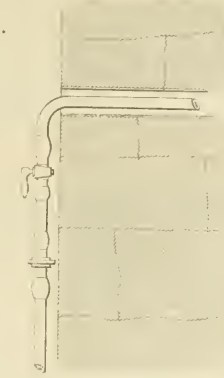


Change of Range Boiler Connections.

water pipe, viz., carried upward from water back and across the ceilings intervening, and connecting at top of boiler.

Thawing Frozen Street Mains.

From S. I. D., *Canada.*—I notice in your issue of February 18 an article on "Thawing Frozen Street Water Mains." Kindly allow me to make a few suggestions. In order to put on a tee, as shown in the article referred to, it will be necessary to wipe on two soldering nipples to provide threads for the attachment of the tee. This will bring the service pipe at least 6 inches from wall, which is not desirable. I think my plan is an improvement. First, cut off the lead pipe a few inches on the house side of the stop and waste and bend the lead pipe so as to give a straight entrance toward the main in street. We have a small boiler which we use in connection with our plumber's furnace to produce steam, which we admit through a coil of $\frac{1}{4}$-inch lead pipe through the spindle of the stop and waste, directly into the main toward the street. The pressure is still on the pipes behind the ice (in nine cases out of ten it can't be shut off on account of the curb-box cock



Thawing Frozen Street Mains.

being frozen also), and in a few minutes the ice plug will be melted and out comes the water. It is now an easy matter to pull out the $\frac{1}{4}$-inch lead pipe and close the stop cock, a good deal easier than it is to start a plug into a tee with the pressure on, when you have 60 or 80 pounds to the inch. If we now wipe on a brass union, as shown in the sketch, we have the thing in shape to thaw out again should occasion require it at any time.

The Chicago Master Plumbers.

The regular semi-monthly meeting of the Chicago Master Plumbers' Association was held at 206 La Salle street, Monday evening, March 27. There was a large attendance and a number of new members were admitted. It was decided to arrange for permanent quarters for the association at 197 East Madison street. A large room is to be secured, which will be connected with the two now occupied by the secretary. Alex. W. Murray, thus affording ample accommodations for the meetings of the association. One room is to be fitted up as a library and supplied with trade papers. Catalogues and circulars of all goods used in the plumbing business will be kept on file for the use of members, and some one will be in attendance to welcome those who may visit the rooms. This arrangement will be found very convenient for those members whose place of business is remote from the business center. If estimates are to be made from plans, they can be taken to the rooms, and by the aid of the catalogues at hand, and telephonic connection with the various plumbers' supply houses, prices readily obtained. The convenience to be derived from having access to the rooms will be of more value than the cost of membership in the association.

TRAPS AND VENTS.

A. J. LAWRENCE, formerly of Johnston & Lawrence, has reopened again in the plumbing and heating business at 211 Alder street, Portland, Ore. We understand that while the trade in that section of the country is quiet at present, there is every prospect of good business in the near future.

A NEW SANITARY WATER PIPE, named the Health, has, we are told, been placed on the market by an English firm. The pipe is formed of an outer casing of wrought iron with a core, or thin lining of pure block tin. It is claimed that as the action of water has no effect upon tin, the water passing through these pipes can have no trace of metallic taint. The pipe is made in all sizes from $\frac{3}{8}$ inch to 4 inches diameter, and in any desired lengths; and connections are made by screw-thread unions, also tin lined, which when screwed on the pipes to be joined, are said to give an unbroken and smooth internal core of tin.

STANDARD MFG. COMPANY, Pittsburgh, Pa., recently shipped by express a carload of enameled baths of special make and design for the Mormon Temple, Salt Lake City. The baths, we understand, are the largest they ever made and are constructed on a scale of great magnificence, the designs being made by Brigham Young's son and Elder Midgely, Salt Lake City. The Mormon Temple is described as a very gorgeous building, the lavatories being finished in onyx, and the baths shipped by the Standard Mfg. Company were made to correspond with their surroundings.

A DELEGATION of the Chicago Master Plumbers' Association, consisting of Daniel J. Rock, J. B. Breen and Alex. W. Murray, accompanied by Wm. T. Geary, vice-president of the State Association, paid a visit to Evanston on Thursday, March 23, to install the officers of the new North Shore Master Plumbers' Association. The visiting delegation was handsomely received and entertained at a banquet.

Tin-Plate Prices.

The fluctuations in prices of tin plates in England during the past 15 years are thus given by Bradley & Burch of London—I. C. cokes, at works, per box, being taken as standard:

Year	Highest	Lowest	Year	Highest	Lowest
1878	$4.00	$3.24	1886	$3.42	$3.00
1879	6.60	3.48	1887	3.60	3.06
1880	7.20	3.48	1888	3.72	3.06
1881	4.32	3.30	1889	3.96	3.30
1882	4.08	3.66	1890	4.20	3.18
1883	3.96	3.84	1891	4.20	3.00
1884	3.72	3.36	1892	3.60	2.82
1885	3.60	3.12			

The explosive character of fine dust made in some processes of manufacture, as in flouring and lumber mills, received another terrible illustration last week, when the flouring mills of Kohler Brothers at Litchfield, Ill., were blown to pieces and burnt, entailing a loss of $1,000,000.

Hot-Air Heating—I.

The following treatise on hot air heating is taken by special permission from the catalogue recently issued by the Excelsior Steel Furnace Company, 110 to 114 South Jefferson street, Chicago. The catalogue has been copyrighted by the company.

Almost all furnace makers give in their catalogues information of a general nature in regard to furnace practice, but as a rule this information is not explicit enough to be of value to the novice who is setting up furnaces, and who desires all the information obtainable, that he may excel in his work and commit no serious blunder. There are to-day in the country, and particularly in the great West, dealers who are deterred from handling furnaces, owing to their lack of knowledge of putting in the work, and who, we believe, will welcome the following treatise, giving, as it does, the results of practical experience in hot-air heating.

In hot-air heating the fundamental principle is that of passing over a heated surface a volume of air and distributing the same by means of pipes and registers to the various rooms to be heated.

The supply of air comes wholly or in part from without the building, and is conducted to the heater by means of a duct, the furnace or heater being located presumably in the basement, cellar or subcellar.

Heaters have been known to be set without any supply of air whatever, and on first-floor jobs have supplied heat to

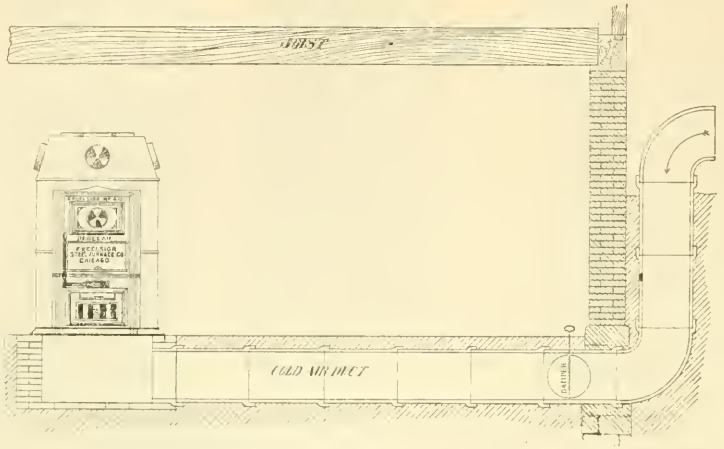


Fig. 1.—Section Showing Cold-Air Duct Running Under Basement Floor and Outside of Wall.

Fig 2.—Plan of Pit and Cold-Air Duct Shown in Previous Figure.

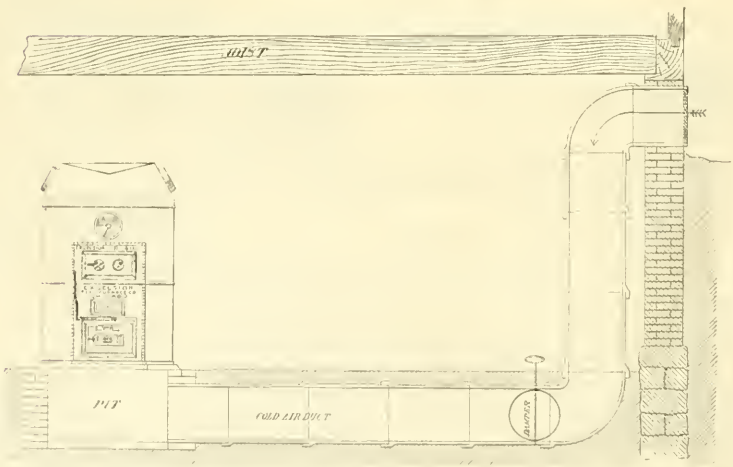

Fig. 3.—Showing Cold-Air Duct Run Inside of Cellar Wall.

the satisfaction of the owners, and, while this is in contravention of all furnace practice, the explanation is simple. The furnace, finding that it is deprived of an air supply, sets about to furnish one of its own, and after heating and expanding the air already surrounding it, within its own casing, proceeds to draw from some one of the pipes leading from it a supply of air. The air thus thrown off is no better than that in any room heated by stoves, and defeats the prime object for which a furnace is placed in a house, which is to provide a healthful heat. No house can be heated successfully without a supply of air to the furnace, and this the next problem is to decide upon the size and character of the cold-air duct which is to convey the air to the furnace to be heated. Inasmuch as the air to supply all the registers and pipes in the house is to come through the one duct, it is evident that the capacity of the duct must be equal to that of all of the hot-air pipes. This does not, however, mean that the area of the cold-air duct must be equal to that of all the hot-air pipes. That would be the case, provided the air without and within the furnace moved at the same pace and that there were no obstructions. The air within the furnace becomes rarefied and expanded, and in rising leaves a the area of the cold-air duct on the inside, which can be reduced to convenient form by the ordinary rules of division. At this point it might be stated that there is no danger of getting the duct too large, for every duct should have a damper for regulating the supply, and if found too large, the capacity can be reduced by turning this damper. Furthermore, if there are various turns and angles in the cold air duct, its size must be greater than set forth, for the progress and velocity of the air will be correspondingly retarded.

Having determined the size of the duct, the next thing is to determine the char-

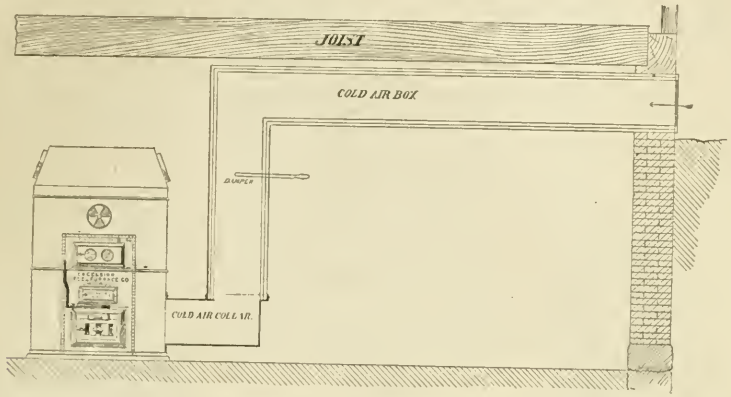

Fig. 4.—One Method of Arranging Wooden Air Duct.

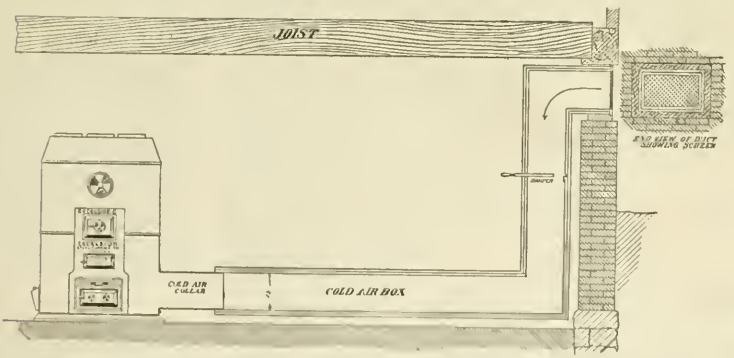

Fig. 5.—Still Another Method.

HOT-AIR HEATING.

supply may come from without or from within, or partly from both.

If only one cold-air supply is to be used, that should come from the outside. It should be taken from the direction from which the prevailing winds come. The reason for this is evident. If taken from the opposite direction when the wind is high, the supply of air from the furnace will be almost entirely or entirely cut off, and cases are on record where the counter current of air from the opposite direction was so strong that a stream of warm air was drawn out from the furnace. Also in sluggish days, when little air is in motion, the furnace needs often more air than it can get unless the wind assists in getting the air into the furnace.

Having determined the direction from which the outside cold air is to be taken, vacuum which the air from the duct makes haste to supply. The air in rising comes in contact with the various parts of the heater, also with the sides and turns of the hot-air pipes and the bars on the registers, and in its division into numerous parts is subjected to more or less friction, which retards its progress, and it is safe to estimate that the air in the duct, when properly built and located, travels 50 per cent. faster than does the air within the furnace pipes. On this assumption, we would say that the cold-air duct should be about two-thirds as great in area as the combined area of all of the hot-air pipes. To ascertain the area of all of the pipes is an easy matter. The square of half the diameter of the pipes multiplied by 3¼ will give the area of each pipe. The sum of the areas less one-third would be acter or construction. This depends upon circumstances. If the soil beneath the house and about it is of a gravelly nature, so that water does not stand around it, an underground cold-air duct of sewer pipe or tile is the best that can be used and can be run from a point without the house, alongside the wall, down to the basement floor level and then turned within the building with an elbow, and continued below the cellar or basement floor to the furnace pit, for in the event of using this form of cold air duct a furnace pit must be constructed of a depth equal to the diameter of the duct. The form and position of this sewer pipe or tile duct are shown in Figs. 1, 2 and 3.

The head or top of this duct should be covered with a wire screen or mesh, so as to prevent mice or vermin or vegetable

matter getting into the duct. If desired, this duct can be begun at a point in the wall near the ground and then turned down the inside of the cellar wall, as shown in Fig. 3, a second turn being necessary in order to change the direction of the duct toward the furnace pit.

The connection between the wall, as shown in this figure, and the underground duct can be made by means of a wooden duct of the same area and constructed of two thicknesses of matched flooring well seasoned and separated by a thickness of asbestos paper to prevent dust or air getting into it in case the boards should draw apart at some future time. The underground section of the duct can also be built rectangular in form and of brick plastered smooth on the inside. These are all variations of the underground duct. The air can also be taken in from all or part of a cellar window, and the connection made to the underground section as described.

If water stands on the soil about the premises, it is not advisable to use this form of a duct, nor should this kind of a duct be placed near to any sewerage pipe for fear that a leakage of the sewerage be absorbed by the duct.

The next form of cold-air duct that we would describe is one made of galvanized iron. This duct can be made either square or round and can be taken from the upper or lower sash of a cellar window or through an opening in the wall. It may take any direction in reaching the furnace, but the straighter the pipe the better. If taken from a sash or from an opening it is a good plan to make a flange to fit the sash or opening and start the duct from this flange, which should extend a foot or more from the opening. The duct can run straight along the ceiling to a point near the furnace, and then by means of an elbow turn down to the base of the furnace and enter the furnace casing by means of a cold-air collar, or, when there is a pit, can connect with a shoulder built out to receive the end of the duct. This form of a duct can be made either round or square.

In building a wood duct from the opening to the furnace, two thicknesses of matched flooring should be used, as before described, and asbestos paper put between. As regards to running of the wooden duct, the remarks concerning the galvanized duct will apply, the duct connecting with the furnace by means of the cold air collar referred to or a shoulder on the furnace pit. (See Figs. 4 and 5, for forms of wooden ducts.)

It is customary in some places, where the ceiling of cellar or basement is not plastered, to take a couple of joists and use them for a duct by inclosing the under side, and then connecting this duct with the furnace by a regularly constructed duct of wood or galvanized iron. The objection to this is the fact that the cold air comes in contact with the floor, and of course cools it, and if there are any openings in the floor the cold air has immediate access to the room. There are times and places when it is impossible to take the cold air from the part of the house from which the prevailing winds come, and in this case the duct should be made one-half larger than directed in the foregoing, and in addition it is advisable to construct within the basement or cellar a reservoir for holding a quantity of air. This can be done by making a compartment about 4 feet square from the floor to the ceiling with matched flooring and a thickness of asbestos paper between, connecting the compartment with the opening to admit the cold air at the top and taking the duct to the furnace from the bottom. This has the effect of making a storage for cold air, and will assist in supplying the furnace on windy days when the tendency would be to draw the air from the furnace.

In city-block houses courts are left between the wings and the cold-air supply is taken from these narrow spaces, and there is much difficulty in getting sufficient air for the furnace, and dealers putting in furnaces in houses so arranged should be chary in giving guarantees, for it is sometimes almost impossible to get enough air when these courts face south and east. When they face the north and west the difficulty is seldom met with.

In setting up furnaces dealers frequently put on the side of the furnace a cold-air slide, and this slide is used in extremely cold weather when the house owner does not choose to burn sufficient fuel to heat the house with cold air entirely, but this slide should not be open at the same time that the outside one is unless there is a shield to prevent the outside air from blowing through the furnace into the basement. Many people depend upon this cold-air slide to supply the furnace and have no outside cold-air supply. The same objection is raised as in case there is no duct or opening, for the air within the house is simply revolved about, and the circulation will be imperfect at the best unless the door leading to the cellar is left open all the time and other conditions are extremely favorable. People having only cold air slides say that if the air is felt to be heavy or impure they ventilate by opening a window in the cellar, but this cools the floors, and, while improving the quality of the air, is not a very satisfactory expedient. The circulation of the air is not materially helped by the opening of a window, for experience shows that to get a circulation an independent duct from the outside must be constructed.

INSIDE DUCT.

The foregoing remarks apply to the outside cold-air duct, and nothing has been said about the inside duct, which is a valuable adjunct to every furnace when used in connection with the outside duct. This inside duct may be built of wood or galvanized iron or of heavy tin and may run from a register placed in the hall or some other room direct to the base of the furnace and enter by means of a cold-air collar or shoulder, as in the case of the outside duct, or it may be teed into the outside duct. In either case care should be taken to prevent the air from blowing from the outside duct up through the inside one. The best place to take the inside cold air supply is from the hall near the vestibule. The reason for this will probably suggest itself. In the first place, the colder the air the heavier and the more readily will it be drawn into the furnace, and near the vestibule in the hall is the coldest place, for whenever the door is opened the cold rushes in at this point and the inside duct will obtain quite a supply in this way of air that is cold and pure. If the rooms open into one another and if the stairs are taken from the front hall the air in the entire house, by leaving the doors open, can be revolved through the inside duct, but if the stairs are inclosed, it is advisable to place a cold-air register in a hall on the second floor and run a pipe duct down through the partition to the basement and connect same to the inside duct from first floor.

The size of register for the inside duct should be equal in area to that of the outside duct, and the advantage in having this duct is that it can be used in connection with the outside one and save fuel, and at night when the lower floor is not being used the inside duct can be used to supply the air to the furnace, for the air not being rebreathed is reasonably pure.

Every cold-air duct whether outside or inside must have a damper for regulating the supply, for in windy weather there are times when it is impossible to heat all of the air that finds its way into the furnace. At night also, when the furnace is not running at its full capacity, the supply of air must be reduced, so it is important that a damper be placed in every duct. In the wooden duct the damper usually takes the form of a slide and in the galvanized and tile ducts it is of galvanized or black iron and round in shape to conform to the shape of the duct.

FOUNDATION.

In case an underground cold-air duct is used, there must be a pit for the furnace as well as a foundation, or rather the pit and foundation are united in one. The pit and foundation are easily constructed. A place is excavated equal in depth to the diameter of the underground duct and about 4 inches larger in diameter than the diameter of the furnace. This pit should be plastered smooth on the bottom with a good quality of cement mortar and the sides walled up to the proper level with good brick laid in this mortar and plastered smooth to prevent water getting in. In the center of a pit thus made it is well to build up a pier of brick about 12 inches square to support the chief weight of the furnace, for without such support furnaces have been known to break down, the rim not being strong enough to carry the weight of the heater and fuel. The depth of the pit should not be greater than the diameter of the underground duct, otherwise the stratum of air below the lower line of the duct will be found to be stagnant. (See plan of foundation in Fig. 2.) Often it is deemed desirable to have a pit even when there is no underground duct, and in such a case the furnace pit is constructed as set forth, but is built with a neck extending out a couple of feet beyond the circle and provided with a shoulder at the top to receive the end of the cold-air duct.

When no pit is required the furnace can stand on a foundation formed of two courses of brick plastered smooth on top. The brick need not be whole, as all that is necessary is a smooth and firm foundation, and bats can be used. In cities the common custom is to concrete the basement floor and then set the furnace on the concrete. This is a good plan and saves the trouble of building a special foundation, and gives the furnaceman some leeway in the location of the furnace. Another and commoner form of foundation in some sections is to build a plank flooring on which to rest the furnace, covering the plank with an iron floor covered with asbestos paper. This is no cheaper than a brick foundation and is not nearly so good, and is not recommended except where brick or stone for the foundation is not accessible.

LOCATION OF FURNACE.

Upon the location of the furnace the successful heating of the house often depends, and it is a matter that requires careful consideration. There are two general rules for locating a furnace which we will give and which in the main should be followed, either separately or together if possible. The first one is that the furnace should be located not in the exact center of the basement nor in the center of the space occupied by the registers, but at a point near the center and in the direction from which the prevailing winds come in winter time. The reason for this is, that air being a vapor, is affected by the winds, and when the wind is blowing strong in bitter weather the tendency is for the rooms on the further side of the house from the wind to be overheated, while those against the wind are poorly heated, the registers on the windward side delivering almost no hot air. Therefore, to counteract this tendency the furnace should be placed some few feet toward the windward side of the building. This rule in general should be followed in order to get a satisfactory heating of the entire house, but there are often in a house two or three rooms that are used for general or

family living rooms in which the greater part of the day is spent, and it is desirable to have these rooms heated even if some others are poorly heated, and in this case the furnace must be so set as to favor these rooms. Should a furnace dealer so set a furnace he should in advance notify the owner of the probable result and protect himself by declining to give an absolute guarantee of the job.

In many plans that are sent us from the country we notice that the bssement or cellar extends under but part of the house and in such cases is usually under the kitchen or dining room, and the furnace has to be located under the dining room, and in many of these houses it is apparent that the furnaceman has no choice in the matter of location, the condition of affairs dictating that the furnace be placed in one spot, even though that spot is not a good one. All that a dealer can do is to do his best and have the house owner understand that the furnace is at a disadvantage and cannot return him the best service of which it is capable. In such jobs the result usually is that the house owner finds a furnace a vast improvement over stove heat, but not entirely up to his anticipations, for he compares the heating of his house to that of his more fortunate friend who has an open basement entirely under his house and the furnace given an opportunity of displaying its accomplishments.

After deciding upon the location of the furnace the furnace setter takes note of the surrounding conditions, the hight of the basement where the furnace will stand, the presence of girders which will reduce that hight, the nearness of partitions that must be considered in running his pipes, and the location of piers, columns or chimneys that impede his operations. He will never find an ideal basement and occasionally will find a basement so full of obstructions that the ordinary rules of locating a heater and running the connections have to be ignored if any satisfactory results are to be obtained, but such cases are rare.

Generally speaking, a furnace ought to stand in a position answering to that outlined in the foregoing, and that part of the basement or cellar where it stands should be at least 7 feet high. If the basement is not that high it should be excavated so as to get that hight, but if the conditions will not admit of excavating, then the basement must be taken as it is and the best work done that the circumstances will admit. If the basement is high the pipes leading from the furnace can be taken off from the top of the heater, but if low the pipes must come from the side of the bonnet. The higher the basement the better, for the greater the elevation of the pipes the greater the velocity of air in them and the smaller the loss of heat by radiation. The cellars of houses when low are at times better heated than the floors above, due largely to the fact that the pipes have very little inclination and lose a goodly share of their heat by radiation. This can be avoided to a certain extent by wrapping the pipes with asbestos paper, but the loss by radiation will still exist to a greater or less extent.

With the location determined and the foundation built, the setting of the furnace is next in order. It is presupposed that the furnace is of good construction and large enough to do the required work, and that ample instructions for setting the furnace have been sent with the furnace, so the only matter to be considered is the way the furnace fronts. The front part of every heater radiates little heat, as that part is taken up to a large degree with the doors and connecting parts, leaving little effective radiating surface, so reason will dictate that the furnace be so placed that the majority of the pipes will be taken from the rear and sides of the heater and that few or no pipes be taken from the part over the front. If the cold air is introduced by means of a cold collar, the collar should be at the back of the furnace, or if at the side, as near the back of the furnace as is possible.

In setting up the furnace each joint should be carefully cemented on so as to render as small as possible the liability of leakage of gas. Most manufacturers send with their furnaces an ample supply of either cement, fire clay or sand for the different joints, but if through neglect these goods failed to come with the furnace they must be supplied. Some joints are better supplied with sand and some with asbestos cement, but as a rule the cement is to be recommended. The article should be the best and used liberally.

The casings sent with furnaces are generally double, or if not double, supplied with a lining of corrugated tin or asbestos paper. If double lining is used sufficient allowance should have been made by the maker for the passage of air between the two. The common flat top bonnet in common use is suitable for general work when the pipes are taken off from the top, but care should be taken to have the bonnet high enough to allow the air to pass freely into the pipes. There should be fully 6 inches of clear space above the radiator of the furnace and the bonnet and if this cannot be had and the pipes be taken from the top of the furnace then another style of bonnet should be used and the pipes taken off from the side of the heater.

Not a little of the success of a job depends upon the form of bonnet used. It will be noticed that some are made with a concavity so that the air is deflected toward the sides and thus given a greater velocity. Also some are made with a 75° pitch, to be used when the basement is somewhat low and others with a 60° pitch to be used when the basement is higher.

Collars are also taken out of the side of the straight bonnet, and this practice is all right when the circumstances demand it, but it is usually better to use the pitch bonnet for side collars.

After putting on the proper bonnet, nothing remains but to cut in the collars and run the connections. It is presumed that the upstairs work has been done, and that the collars are in all boots and boxes so the operation of running the connections would be in this manner:

Take the required number of casing collars of the proper size and style and place them on top of the bonnet, taking care, of course, to place each collar of the right size as nearly in a line as possible with the collar on the boot or box with which it is to be connected. A knowledge of the rooms above will tell you whether any particular room is to be favored, and, if so, in placing this collar place it where it will get more heat than some of the others. This can be done if the collars are taken from the top by placing the collar well in toward the center of the bonnet, while the others you can place near the edge—that is, within 2 or 3 inches of the edge. Having arranged the collars on top of the bonnet, provided the hight will admit, and in their order they can be cut in.

The turn from the hot-air pipe into the register box collar or boot collar is made with a regular square elbow and the elbow should be wired the same as the sections of the hot air pipe.

If the stacks, boots and boot collars, registers, boxes and box collars are already in, the furnace dealer has to make his connections irrespective of whether or not they are of the proper size and properly put in, and though the work of putting in the heater is rightly and carefully done and the basement work is of sufficient capacity, if the work above the basement is not put in properly good results cannot be hoped for. Therefore, it is of importance to consider the way this work should be done, so we will take a glance at the upstairs.

(To be continued.)

Hot-Water Fountains in Paris.

Le Génie Civil, a French engineering journal, describes a novelty in the line of public conveniences which has recently been inaugurated in the city of Paris. The object consists in a device for supplying hot water to the public from street fountains at the minimum of cost. The fountains, of which 20 have already been erected in different quarters of the city, are similar in appearance to the newspaper kiosks so familiar to visitors in the French capital. The hot water is delivered automatically upon the insertion into a slot of a small coin in value corresponding to an American cent, pressing at the same time a button, which sets in motion the mechanism contained in the fountain. The invention is due to a Monsieur Robin, who has brought it to perfection after years of work in similar lines of effort—namely, the utilization of gas for heating purposes.

The water is heated on the spot by an ingenious system, which may be briefly described as follows: A syphon at the base of the column containing the fountain is in communication with the city water supply. On a piece of money being placed in the slot and the button being pressed, a simultaneous motion is given to the various portions of the mechanism. The cold water flows into a receptacle, from whence it is drawn up into a spiral heater, with many coils, formed of 125 feet of copper tubing, placed at the corner of the fountain. The heater forms two separate parts, each heated by a gas burner made with a number of small holes, from which the gas escapes and is lighted by a small central burner, always kept aflame. The heating burners are only lighted long enough for heating the water, the gas for their use coming from the meter only while the water is flowing through the coils of the heater, and then being automatically cut off until again liberated by a fresh start of the mechanism. The heaters, presenting a very large heating surface in their numerous coils, quickly bring the water up to a temperature of 140° to 175° F. After circulating through the heater the liquid flows into a pipe discharging into the vessel placed to receive it under the spout of the fountain. About 10 quarts of hot water are heated each time, and but a few moments are required for the process.

In giving their permission for the erection of the fountains, the Municipality of Paris stipulated that they should be erected near the back stands, in order that the cabmen should be able to fill their heaters readily with hot water, in place of using the dangerous charcoal fuel, which has caused so many accidents in Parisian vehicles. This is one use to which the hot water is put. There are numerous other purposes for which the fountains will furnish a welcome supply of hot water to the poorer classes for domestic use, cooking, supplying hot baths, &c., in quarters where kitchen conveniences are not abundant. In numerous ways a ready supply of hot water for a cent will be a great boon, and should make for cleanliness and sanitary improvements, especially in the crowded slums and alleys of the city, where such improvement is most needed. The innovation seems to recommend itself as a useful and practical boon, and appears to be one which could with advantage be adopted in other cities, provided the initial cost of the fountains be not excessive.

ROOFING AND CORNICE.

Combination Scraper and Tin Cutter.

From W. N., *New York.*—For the benefit of tin roofers, who have more or less repairing to do, I submit a sketch of what I think is a new tool—namely, a scraper and a tin cutter combined in one. When repairing tin or galvanized iron roofs, after the defective sheets have been found, it is usual to use a chisel and hammer and cut out the defective spots, and then use a scraper with which to scrape a smooth, bright surface on the old tin or iron, so that a joint can be made with the new metal.

Or a case may arise where an old tin roof is being ripped up to make place for a new roof. Before cutting, the old tin roof. In practice the tool is grasped near the end B with the left hand, and taking in the right hand an old mallet, which has already done its duty in pounding down locked seams in tin roofing, the blows are struck as indicated in Fig. 6, moving and striking the cutter alternately.

Fig. 7 also shows a section through a tin roof with the scraper in position for use. In using the scraper, the end A, Fig. 7, is raised as shown, and, taking the scraper in both hands, a downward pressure is exerted, at the same time drawing the scraper backward and forward until a smooth, bright surface is obtained.

Gas-Tar Roof Paint.

From BRUSH.—The gas-tar roof painters are abroad in the land, and at present are painter was receiving all the credit, I stopped doing his work, but he continued in the same course, going from one tinner to another to get his work done, while he and his paint received the credit for tight roofs. Will the readers of *The Metal Worker* give their opinions regarding the use of gas tar as a paint for metal roofs?

Note.—The general opinion among roofers is that gas tar is injurious, as the acid or other corrosive principles in the tar causes tin or iron to rust.

Double-Locked Seams.

From A. B., *Portsmouth, Ohio.*—Inclosed you will find a sample of two pieces of valley tin joined together by a double-

Fig. 1.—Slow Method of Cutting a Tin Roof.

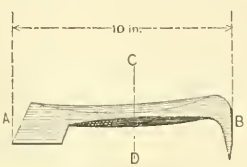

Fig. 2.—Side View of Combination Scraper and Tin Cutter.

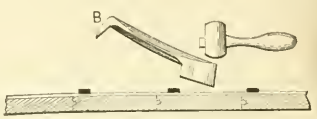

Fig. 6.—Section through Tin Roof Showing Cutter in Use.

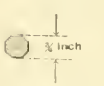

Fig. 3.—Section through C D.

Fig. 4.—End View of Cutter at A.

Fig. 5.—End View of Scraper at B.

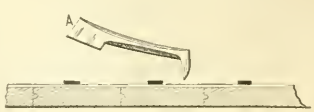

Fig. 7.—Section through Tin Roof Showing Scraper in Position for Use.

COMBINATION SCRAPER AND TIN CUTTER.

roof is usually divided into sections, cut and measured, rolled up and tied and the size and number of square feet in each roll marked on the outside, so that in case a piece is wanted of a given size, it will not be necessary to open the roll again for measurement. If defective sheets, or an old tin roof, were to be cut out, using the hammer and chisel shown in Fig. 1, a great amount of time and labor would be lost. To avoid this, and have the scraper and cutter combined in one, there is shown in Fig. 2 a side view of a combination tool for the purpose. The cutter shown at A is used to cut out the old sheets, and the scraper shown at B is used to obtain a bright surface on the old metal. The scraper is made from ¾-inch octagon steel, and, as shown in Fig. 2, should be 10 inches long when finished.

Any blacksmith or tool maker can make the scraper to order, Fig. 2 giving a good idea of how the tool should look when finished. Fig. 3 shows a section at the line C D shown in Fig. 2; Fig. 4, the end view of the cutter shown at A, and Fig. 5 the end view of the scraper, shown at B. Fig. 6 is a section through a tin roof with the cutter in position when for use.

It will be noticed that the end B is raised so that the point of the cutter touches the painting our town black with the injurious substance, thus doing an injury to those mechanics who endeavor to do good work. The gas-tar painters call on the real-estate agents or owners of buildings and make outrageous statements, claiming the material to be water proof, fire proof and weather proof generally, calling the article by various names, as plastic slate, graphite paint, &c. From what I have learned regarding their operations, they go to the gas works and buy gas tar, which they mix with gasoline, and apply this composition to roofs, charging from 50 to 75 cents per square. Then they promise to make leaky roofs tight by the use of this thin paint. I have been working for one of these roof painters who has taken contracts to paint and repair roofs. When he first commenced operations in town he put clay on the cracks and holes in roofs and gutters. Finding this material would not hold, he engaged me to do the repairing with solder; thus he and his material received the credit for making the roof tight. As he would represent to the owners or agents of buildings that his paint was what prevented the roof from leaking, no extra charge was made for repairs, consequently my bill was a dead loss to him. Observing that the coal-tar locked seam. I use this style of seam for all valley tin, also for gutters, &c. It is not necessary to solder the seams. I have found that they are tight, and will not leak when used for this class of work. What is your opinion of this style of seam, as the sample shows?

Note.—The sample sent us by our correspondent shows two pieces of tin joined together by a double locked seam. This seam is stronger and possesses other advantages which would recommend it to roofers in preference to the common single-lock cross seam for some kinds of work. Although by no means a novelty, it is not used as much throughout the country by roofers generally as its merits deserve.

Measuring Standing Seam Roofs.

From R., *Rhinebeck, N. Y.*—Is it customary for tin roofers to measure in the standing seams when taking a contract for a standing seam tin roof by the square?

Note.—A custom that prevails in one part of the country may not in another; accordingly, it would be difficult to give a

fixed rule for the measurement of standing seam tin roofs. We think it is the general custom, however, not to measure in the standing seams when estimating on roofing by the square. As this is an interesting subject to roofers, we invite our readers to express their opinions and tell what custom prevails in each locality.

Roofing Slate.

In an article contributed by George H. Harris to a recent issue of *Stone* on the subject of Slate and Slate Quarrying, interesting reference is made to the manufacture of roofing slate. He states that a block is raised from the quarry and placed in close proximity to the building occupied by the slate makers. The block is then either sawed across the grain or broken by one of the slate makers, so that a certain sized slate may be made from it. It is then split into pieces 2 inches thick, and the slabs pass to the second slate maker, who cleaves them as thin as the quality of the slate will permit. We quote from the description as follows:

A hundred slate set upon edge and packed closely together should occupy 22 inches in space. Where the cleavage is imperfect the slate makers do not obtain more than three or four slates to the inch. A slate trimmer, which cuts the slate into regular sizes, is indispensable, and is always found in every slate maker's building. In cleaving slate down to the proper thickness there may be a blind seam or some obstacle which breaks the slate. This piece is cut with the slate trimmer into a smaller-sided plate. For instance, the block is first designed to make 24 x 12. Defects may occur so that they may get a few 24 x 12, or a few 20 x 12. The sizes of slate vary from 12 x 6 to 24 x 18 The most salable sizes commence at 20 x 10 and run to 24 x 18. Allowing 3 inches lap, when laid, there are 533 pieces in a square of slate which measures 12 x 6 inches. In 24 x 18 there are 76 slates to the square. A square of Vermont slate will weigh about 600 pounds. In order to furnish a yard so that there is a sufficient number of slate on hand to make sales from it will be necessary to have at least 100 different sizes of slate, and a carload is 50 squares of each size. At W. H. Lloyd's quarry, near Fairhaven, Vt., which is devoted exclusively to purple roofing slate, a gang of three men will make 15 squares of slate per day. The crushing strain of Vermont slate, which has been tested by F. R. Hutton, M. E., of New York, shows the resistance to be 12,870 pounds to the square inch. The durability of Vermont slate cannot be determined, from the fact that the first slate, which were quarried 46 years ago, and the first buildings which were slated from these slates, about the same time, are in as good condition to-day as they were the day they were first placed upon the roof, with the exception of an occasional breakage.

There are slate quarries devoted to roofing slate entirely, while there are other producers who manufacture mill stock and also roofing slate.

Many firms throughout the slate belt, having become well satisfied in regard to the superiority of the Vermont slate, are willing to place their goods in competition with any foreign article of a similar nature. Foreign demand for colored slates has gradually increased within the past four or five years, so that at the present time this branch of the slate industry has become a matter of considerable importance.

Since the "tide in the affairs of men" has changed, it may be proper to mention the first slate quarries developed in the Vermont and New York slate bed, and at a time when the people of New England were entirely dependent upon foreign markets for slate. It has been stated that the first quarrying in Vermont was done by Col. Alanson Allen of Fairhaven, in 1839. In 1847 Mr. Allen commenced the manufacture of roofing slates. In 1848 F. W. Whitlock of Castleton, Vt., opened a quarry in that town about forty rods north of the north line of Poultney, and in the vicinity of a quarry opened afterward and called the Eagle quarry. In 1851 Daniel and S. E. Hooker opened the first quarry in the town of Poultney, Vt. In 1852 John Humphray opened the Eagle quarry, near Hydeville, Vt., and E. D Jones opened a quarry in the same vicinity. In 1853 the Eagle Company were incorporated and commenced the manufacture of roofing slate under the superintendence of Dr. Goldsmith. W. L. Farnham & Son opened a quarry in 1853, and in 1860 Mr. Griffith Hughes opened the "Evergreen," previously mentioned. The year 1860 seemed to be prolific in opening and developing quarries. Six were opened in that year. The increase was slow—about three or four new quarries being added to the list every year up to 1872—when there appeared to be a decided change, and quite a number of new quarries were included in the list that year. The product of the slate quarries amounted to but very little previous to this time, on account of the slow methods of quarrying. But very few if any of the modern mechanical appliances were in use at that time.

The pioneer who commenced active operations in developing slate quarries 40 or 50 years ago is worthy of a great deal of credit for his foresight, his indomitable will, sagacity and perseverance, and yet it must be admitted that the prosperity of the slate industry has been developed within the past 20 years. The demand for slate makers and quarrymen from the old country or from Wales appears to be greatly in excess of the supply. A slate maker in Wales receives about $1 per day wages, while the laborer performing the same labor in this country gets $2 for the same time. A family which consists of a man and his wife and five children arrived in this country last fall. The husband and two boys were given work at the Eureka quarry. The first month's labor revealed the fact that the second boy, who was only 10 or 11 years of age, had earned more as a signal boy in this country than his father had earned in the same time as quarryman in Wales. The father, in the meantime, had more than trebled the wages he had received in Wales.

The importance of the slate industry and the magnitude of its trade is demonstrated in the large number of orders that are being received from foreign markets. The export trade has nearly doubled in the past two or three years.

The annual output of roofing slate throughout the slate belt of Vermont is between three and four hundred thousand squares. Vermont produces a greater variety of colored slates than any other State, while the output of her milled stock is larger than that of any other State.

FLASHINGS.

THE GROWTH of the iron roofing industry has been very marked in recent years, for, whereas a decade since there were not over a dozen iron-roofing concerns in the country, there are now hundreds. This rapid increase is ascribed to the excellence and cheapness of iron for building material and its lasting and fire proof qualities. Corrugated iron for roofing and siding of buildings has been used to some extent for the last 50 years, but in the early days the excellent quality of shingles used and their comparative cheapness necessarily limited the use of iron. To day, however, iron and steel are very commonly employed in building construction. Many persons who have not previously used corrugated iron are in doubt as to its durability and as to whether it is adapted to their particular needs. Such persons are likely to find intereat in a little pamphlet entitled, "The Life of an Iron Roof, or, How Long Will It Last," issued by the Cincinnati Corrugating Company, P. O. box Q. Piqua, Ohio. This book, which the company are sending free to applicants, gives full information to those contemplating the use of iron or steel for building purposes.

E. J. JOHNSON & Co. of 38 Park Row, New York City, have engaged as traveling salesman Wm. Davis, who will solicit trade in the State of Ohio. This concern are now large shippers of all grades of roofing slate.

M. H. DEVEY of Chester, Pa., has patented a roofing cement, which he claims to possess many advantageous qualities. It is made from formulas covering glass, slag, slate and marble mixed or compounded with linseed oil and other materials. He states that it is undisturbed by the greatest alternations of heat, frost or thaw, and is as well adapted for a complete roof as for repairs. It is put up in 2 pound cans.

R. B WHITTEMORE, secretary of the American Roofing Company, St. Louis and Cincinnati, will shortly leave for an extended trip in the interest of his company. Among the points he will make are the principal Texas jobbing centers, through New Mexico and Arizona and Southern California; then north to San Francisco, Portland, Tacoma, Seattle and Spokane; thence east, stopping at Salt Lake, Denver, Kansas City, &c. The American Roofing Company have built up an extensive trade in the sections above enumerated, and advise us that their business on the Coast is steadily increasing.

WE HAVE RECEIVED from the Kansas City Metal Roofing & Corrugating Company, successors to Jerome Twichell & Co., Kansas City, Mo., a sample of the sheeting which they are furnishing the trade. This sheeting is claimed to be water proof, clean to handle and obnoxious to mice and vermin of every description. It is made 3 feet in width and put up in rolls of 500 square feet. It is referred to as being warm in winter, cool in summer and healthful all the year.

THE HEBERLING METAL ROOFING COMPANY of Havana, Ill., issue a four-page circular relating to their Quick-Laid and Matchless brands of iron, steel and American tin roofings. Illustrations are presented showing how the seams are made and the manner of applying the roof to a building. Descriptive particulars also tell how the work is done. Attention is invited to steel brick siding, iron weatherboard siding, beaded and panel ceilings, and also to the company's steel paint.

THE ANNOUNCEMENT is made to the trade that the firm of Holmes & Whitney, West Superior, Wis., are dissolved. In order to meet the requirements of the largely increased business of the I X L Cornice Works and provide additional capital and facilities for the prompt execution of contracts, a copartnership has been formed between A. E. Holmes of the former firm of Holmes & Whitney and J. E Lecour, formerly of the firm of Burdick & Lecour, the new firm to be known under the name of Holmes & Lecour. It is the intention of the new firm to conduct a general cornice, skylight and roofing business. They also mention that they have secured the exclusive agency for the hot-air furnaces and heaters manufactured by the Superior Furnace Company of New York, and will make a special feature of heating and ventilation.

"The Metal Worker" Competition in Skylight Pattern Cutting.

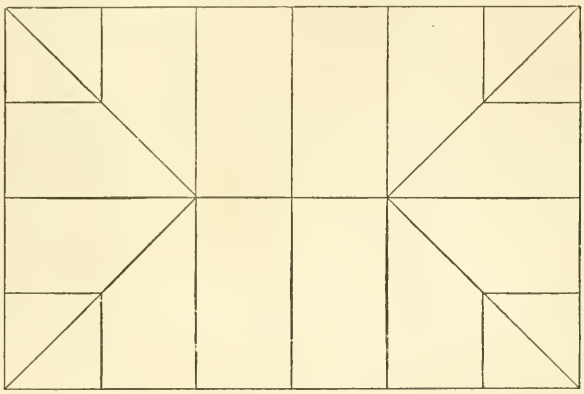
FOR the purpose of calling forth from the readers of *The Metal Worker* the best method for obtaining the patterns of a hipped sheet-metal skylight and to advance the art of pattern cutting, it has been decided to present a prize competition, the particulars of which are as follows :

Each contestant will be required to furnish the plans, elevations, necessary sections and profiles of skylight, also to design the various parts of same, giving to each part the shape that may be considered best adapted for the purpose ; drawings to be of such size as required for publication in *The Metal Worker*.

The skylight to be so constructed that the condensed moisture from below will be conveyed outside, the frame work of skylight to be made of sheet metal, and the usual thick glass to be used in connection with same ; the method of securing glass and caps to bars or rafters to be clearly shown.

While the plan may show a certain size of skylight, indicate the method by which one of similar pitch but different size can be constructed, the same miter patterns being used.

Show method of obtaining length of the various bars or rafters, using for the purpose any diagram, plan or elevation that may be necessary. Also show method of obtaining shape or section of hip bars.



Outline Plan of Skylight.

The skylight for which the patterns are required is such as would be placed over a light shaft, or on a roof or bulkhead, the size of opening being about 4 x 6 feet. As there is no particular rule governing the pitch of the skylight, it can be given such pitch as may be desired. While the wooden curb or frame of air shaft, roof or bulkhead is supposed to extend a sufficient distance above the roof to give ample opportunity for securing skylight to same, contestants will be at liberty to use such methods as appear best adapted for the purpose of fastening skylight, where brick and angle iron constitutes the frame.

The accompanying plan is not intended to give details of construction, but to indicate in a general way the shape of skylight for which drawings and patterns are required. Where there are two or more similar parts in the skylight, so that the pattern for one part will answer for the other, it will be only necessary to show details of one part. As indicated in plan, the skylight is to have a hipped roof, and as previously stated, the roof can be given any desire pitch.

PRIZES.

In the contest above described, two cash prizes are offered, as follows :

First prize.....$75.00.
Second prize..... 50.00.

The drawings and accompanying description may be sent by either mail or express, charges prepaid, and must reach the office of *The Metal Worker* not later than April 1, 1893.

They are to be addressed as follows :

THE METAL WORKER,
96–102 Reade street, New York.
(Skylight Competition.)

Each contestant is to select a fictitious name or device, which is to be placed on the description and each sheet of the drawings. The real name and address of the writer is to be put in a sealed envelope, on which is to be placed the fictitious name or device used on the drawings. This envelope is to be inclosed with the drawings and description.

The manuscript and drawings are to be sent flat, not rolled, and the writing should be on one side of the paper only. It is also suggested that legal cap paper be used for the description, the same size of paper for the drawings, and that ink be used for writing the descriptions ; the drawings to be either ink or pencil.

The various drawings and descriptions received up to the time set for closing the competition will be submitted to a committee selected for the purpose, who will decide between competitors.

In deciding between contestants, four points will be given consideration, as follows :

1. Originality.
2. Mechanical completeness of the method proposed.
3. Neatness of drawings submitted.
4. Clearness in description.

The right is reserved to publish all the drawings and descriptions received in this competition, and also to return to the authors the drawings and descriptions received in the competition in case they are not considered suitable for publication or worthy of an award of prizes.

THE RETAIL STORE.

Stove and Tin Store.—IV.

BY VETERAN.

The dull season is what dealers dread, particularly those who are not prepared by abundant capital to stand the loss that often follows long seasons of depression as well as the regular and expected dullness of others. When the question comes up whether it pays to make tinware, the answer depends upon what else could be done if it was not made. Good workmen can usually command steady employment and it would be better to have them make tinware than do nothing but kill time, as they will rather than get laid off, or for the employer to lose their work. A good IX tin wash boiler has from 75 to 80 cents worth of stock in it, and a man can make ten in a day. They sell at retail for $1.50. Some are sold as low as 90 cents at wholesale that are called IX tin, but they are in no respect equal to a good workman's job. They are coke tin and are not fit to sell for a good boiler. Extra heavy tinware shows still larger margins for the work, and in all leading articles can be made in the shop if the workman has the spirit of enterprise in him and does not think it too great a tax on his mental faculties.

A good workman will study his employer's interests and show a willingness to do what he can to help out in the dull season. Such a man will go from an outdoor job to making tinware and not pretend that they are two different classes of work in which he cannot do both well. I do not think this applies to all small or very fine work, like tea and coffee pots; but there was a time when these were made in regular jobbing shops, and made well and in fancy styles. In large factories of pieced tinware there are not many machines used except the regular set, but they are used lively and kept in good order. Most of what the wholesale dealer makes on it is saved by cheap labor and purchasing material in large quantities. To offset against that, the retail dealer has no extra office or shop expense, no traveling men to pay, and can often work in his own labor.

The dull season can also be bridged over by special effort to obtain a share in the furnace work, which is often done when the stove and tin work is at a standstill. July and August are good seasons for furnaces, and also for conductor pipe—or "leader," as the country boys will call it. There is a good deal of talk of the superiority of patent conductors, but I took one down lately that had been up but four years, completely rusted out, and replaced it by a plain pipe of heavier material. Within a few days I also took down a 3-inch tin conductor, hand made, and well made of IX tin, that had been up 17 years. The owner insisted on its being of the same material, and I soldered the seams and painted it inside and out—the inside by placing one end in a pail and on a slight incline, pouring the paint into the upper end and turning it around as it went down.

When I hear a tinsmith who is not driven with work all the time say he can buy his tinware pipe and stove trimmings cheaper than he can make them, I hear other things about him also. Usually he had rather take life easy and tell stories than work. I have no intention or desire to cry down the large manufacturers; they are a necessity to the business and set an example of skill and enterprise that gives points to any workman. While many are flooding the country with worthless goods, the buyer is to be blamed for it alone. When a man attends to his business faithfully during the busy seasons and pays his bills at maturity, he can't employ a portion of the dull season any better than in taking a rest and bracing up for the fall trade. Valuable inventions have often come through resting the body and allowing the mind and eyes to do fine work.

T. P. CARRUTH, Orange, Mass., who was completely burned out about a year ago and since then has carried on business in temporary quarters, has re-located in a handsome new building, where he has a store of convenient size and arrangement, which was opened to the public with dedicatory ceremonies March 16.

The American Gas Range.

The illustration presented herewith shows a new gas range brought out for the season of 1893 by Robert Schueler & Co., 615 Ogden avenue, Chicago. This range, with water heater, has six cooking holes, making a very large top cooking surface The water heater, placed at the left side of the range, as shown in the cut, contains a coil of six pieces of ¾-inch heavy wrought-iron pipe, under which are placed two long burners, which distribute the heat evenly over the entire surface of the coil, thus raising the temperature of the water very quickly. The manufacturers thus describe the general construction:

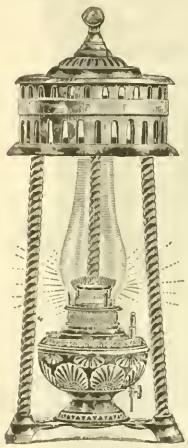
American Gas Range.

The body of the range is made of cold rolled heavy refined steel, with cast-iron front, top and doors. Doors, name plate and trimmings are heavily nickel plated. The oven is heated by double radiating burners placed underneath a sheet of steel ½ inch from the oven bottom. In this way the flame from the burner never comes in direct contact with the oven bottom. The flues are so arranged that the heat passes up both sides over the top and down the back, escaping at the flue in back. Every square inch of the oven surface is thus exposed to the action of the heat. It is obvious that under this arrangement the fumes from the burning gas do not come in contact with the contents of the oven. The range has large, powerful burners of the latest design, having no

loose caps to cause leakage of gas. An automatically hinged drop door forms a strong and convenient shelf when open, the desirable features of which will be readily appreciated by all housekeepers. The hight of the range is 33 inches. The top cooking surface is 25 x 34 inches, with 6 and 7½ inch holes. The oven is 17½ x 18 inches and 12 inches high. The broiler is 17½ x 19 inches and 8 inches high.

Edwards Parlor Lamp Stove.

In the accompanying illustration is presented a general view of what is known as the Edwards Parlor Lamp Stove, which is being placed upon the market by the Edwards Parlor Lamp Stove Company, of 238 East Lake street, Chicago, Ill. The manufacturers claim for this device that it is so constructed that it may be used for both heating and cooking purposes. It is 34 inches high, 13 inches in diameter and is finished in nickel plate, highly polished. The lamp may be used independently either as a hanging or standing lamp for lighting purposes, the makers claiming that it gives a light of 300 candle power. The illustration which we present herewith shows the device as used for heating purposes, the air in the room passing through the tubes into the

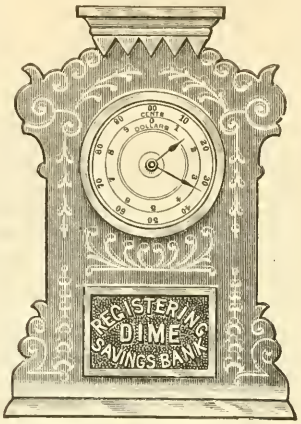


Edwards' Parlor Lamp Stove.

radiator, where it is raised to a high temperature, and then escapes to the room, thus maintaining, it is claimed, a constant circulation. By removing the two covers the heating stove may be turned into a cook stove, and the makers claim that it operates without any disagreeable odor, smoke or soot. The device is simple, entirely new, and is offered the trade in a variety of styles, adapted for burning either oil or gas. By removing the lamp from the footpiece and placing it on top of the radiator, the heating and cooking stove is changed into an ornamental parlor lamp.

Clock-Registering Savings Bank.

T. G. Ellsworth, 85 Chambers and 67 Reade streets, New York, agent for A. H. Walker, Brooklyn, N. Y., is introducing the dime clock bank, as herewith shown. The minute hand registers the cents and the hour hand the dollars that are in the bank at any time. The operation of the bank is described as follows: The bank is automatic in its operation; the first dime that is put in locks the bank and registers 10 cents. Each subsequent dime deposited is indicated upon the clock dial, and the one hundredth dime deposited unlocks the clock so that the door may be opened and the $10 taken out. The clock is finished

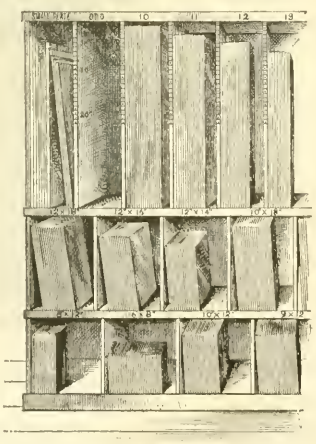


Clock-Registering Savings Bank.

in three colors of bronze and presents an attractive appearance.

Glass Rack.

We are indebted to the Hawks Hardware Company, Goshen, Ind., for a sketch of the Glass rack shown, which is referred



Glass Rack.

to by them as very convenient. A feature of this rack is the marking of sizes on the upper row of openings. The width only is marked above the openings, accommodating Glass from 10 to 24 inches wide; and spaces are also provided for small Plate Glass and odd sizes. The length of the Glass is designated on each partition, the markings running from 40 inches down to 18 inches. The smaller sizes of Glass are designated as usual, length and width of each size being marked above each opening.

T. S. Stewart, formerly of Springfield, Mass., has opened a new store in Orange, Mass.

The Hardware Club of New York.

A meeting of the recently elected Board of Governors was held at the office of Wiliam H. Williams, March 24, when in accordance with the requirements of the constitution the governors were divided by lot into three classes, holding office for one, two and three years respectively, with the following result:

For one year: Eugene Bissell, Thomas F. Keating, James H. Kennedy, John L. Varick, R. R. Williams.

For two years: Alfred D. Clinch, Charles Daly, Brace Hayden, Mortimer C. Ogden, Webster R. Walkley.

For three years: Arthur G. Sherman, Robert H. Swayze, Peter McCartee, W. H. Williams, E. C. Van Glahn.

The governors then proceeded to the election of officers with the following result:

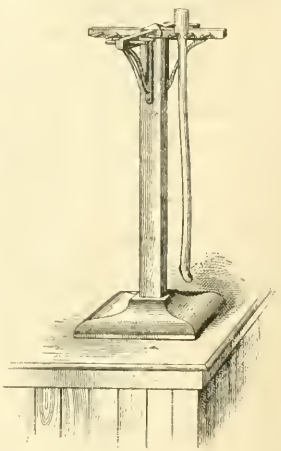
President, William H. Williams.
Vice-president, Robert H. Swayze.
Treasurer, Thomas F. Keating.
Secretary, John L. Varick.

It will thus be seen that the former officers were re-elected.

In accordance with the resolution adopted at the annual meeting of the Club, the treasurer was authorized and instructed to issue a circular calling for the payment of initiation fees.

Axe-Handle Rack.

We are indebted to S. J. Smith of Miller, Smith & Co., Chadwick, Ill., for a sketch of the Axe Handle rack shown. The post, which is 38 or 40 inches long, stands upon a base, the whole designed to stand on the counter. The cross pieces at the top of the post are held in position by brackets and have pegs or prongs 11



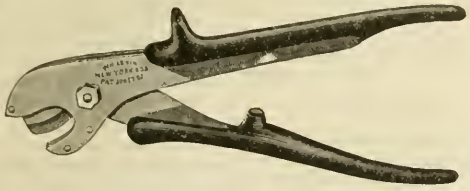
Axe-Handle Rack.

inches apart, between which the Handles are hung. The racks are made in three different sizes.

D. S. Decker of Wells, N. Y., has recently purchased a half interest in the stove and tinware business of Hon. John J. Hanson of Gloversville, and the firm name will be Hanson & Decker.

The Levin Pruner No. 2.

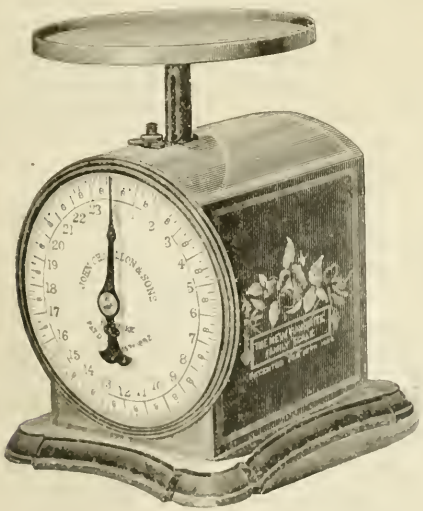
The Levin Pruner Company, 37 Dey street, New York, are offering the pruning shear herewith illustrated. It consists of two steel plates riveted at the three points shown in the cut, between which the cutting blade is pivoted and works, while the handles are of malleable iron. A long flat steel spring concealed between the plates of the upper handle opens the pruner. In operation the blade after the cut is made passes between the plates of the lower handle and is prevented from cutting against the rivets by the stop between the handles. The point is made that the pruner makes a smooth, clean cut like a knife. The manufacturers claim that though the pruner is capable of cutting through half an inch of dry oak it does not hurt the hand, jar the arm, or tire the operator in any way. The pruner is made in two sizes, No. 1, 7 inches long, No. 2, 9 inches long, and put up one each in neatly finished paper box.



The Levin Pruner No. 2.

New Favorite Family Scale.

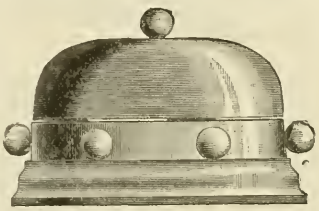
John Chatillon & Sons, 85–89 Cliff street, New York, are offering the scale here shown, which will be known as the New Favorite. The main difference between this and the Favorite is the material of which it is made and the method of construction. This scale is manufactured of sheet steel, making it light and strong, instead of cast iron, as heretofore. The risk of breakage in handling or shipping is minimized, and the freight charges reduced, as its weight is but about one-half of that of the cast scale. They will be made in four sizes, 5, 12 24 and 48 pounds, and in three styles, with platform, platform with scoop, and fork with scoop; These goods will be known by the same numbers, descriptions, &c., as applied to the Favorite, the manufacture of the cast scale being entirely discontinued.



New Favorite Family Scale.

Improved Revolving Table Bell.

The Hardware Specialty Company, Newark, N. J., C. F. Guyon Company, 99 Reade street, New York, agents, are offering the revolving table bell here illustrated. The central portion, to which the knobs are attached, revolves on a pinion attached to the base. When operated, a simple gearing connecting the base and center causes a circular brass plate, to which two loose hammers are attached, to revolve, which, striking against the gong, produces the effects of an electric bell. It has no complicated mechanism, springs or wires to get out of order, requires no winding, and is always ready for use. It is made in two sizes, 3 and 4 inch, and two finishes, nickel plate and quadruple silver plate.



Revolving Table Bell.

Myers' Combination Spray and Vermorel Nozzle.

F. E. Myers & Bro., Ashland, Ohio, are furnishing this nozzle, as illustrated herewith, in combination with their bucket spray pumps and barrel spray pumps.

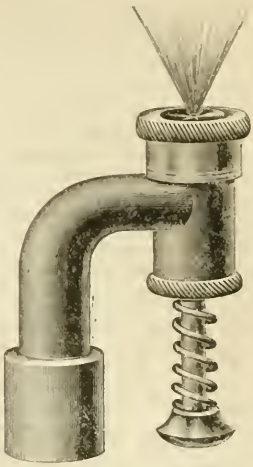


Fig. 1—Combination Spray and Vermorel Nozzle.

The spray nozzle is arranged so that the male end will thrown a solid stream. It is explained that by placing on the sprinkler tip it becomes a complete sprinkler for use in connection with flower beds and for any purpose where a sprinkler is required, and that the spray nozzle throws a spray as fine as mist. The point is made that with this combination the operator is able to throw a solid stream, to sprinkle or spray, giving the full use of the pump for any requirement necessary. The vermorel nozzle is constructed to throw a spray as fine as mist, and is supplied with two different caps, so that the quantity can be changed. It is also provided with a needle attachment to open up the port should it become closed with any sediment or particles that may be in the material used in spraying. The manufacturers state that the nozzles cover the requirements for spraying fruit trees, shrubbery, &c., and that they are furnished in connection with the Myers barrel and bucket spray pump

Waste in the Store and How to Avoid It.

FIRST ARTICLE.

By W. T. Warsop.

This is a subject worthy of attention, as the losses which occur to the dealer in the course of the year, from what may be termed waste, are considerable.

One of the first items is over weight and measure. Good

WEIGHT AND MEASURE

may be due the customer, but need not run to excess, and the salesman who makes a practice of throwing in a little more after weighing correctly is working against the interests of his employer, and if continued in will easily lose from 1 to 2 per cent. of the net profits for him. Very often this overweight and measure are given by salesmen who are not accustomed to weigh and measure goods, and it would be to the merchants' interest to give them a few lessons to perfect them in weighing and measuring goods.

Let them take 100 pounds of some article and weigh it up in 2, 3 and 5 pound packages so carefnlly as to make the requisite number of pounds. I think the result will surprise them.

OMISSION TO CHARGE

goods sold on credit is something that has cost most dealers quite a sum during their business career. Various reasons would doubtless be given for this should the salesman be questioned, but a very common reason is because it is not quite convenient to step to the desk to make the charge.

This could be corrected in a great measure if the salesman was obliged to carry a memorandum book for that purpose in his pocket, and to make the charge on same so that it will not escape his attention until he has an opportunity to report or make charge himself on the proper book.

Neglect to charge goods will also occur when the customer uses a passbook; the charge often made on the passbook is neglected on the store book. The way to avoid this is to first make the original charge on either of the books mentioned before, then copy same into the passbook.

KEEPING BOOKS POSTED.

Losses occur from neglect to keep books posted. A customer calls for the amount of his account; the merchant turns to his account on the ledger and gives him the amount, but finds in a few days (or sometimes weeks) in posting that there are a few more items that should have been added to his account, and these items, if small, are often lost, as the customer, if spoken to about it, refuses to pay, or does so unwillingly, or his trade may be lost because the customer is not a regular one.

A TRIVIAL MATTER.

There are many instances, too, when a thoughtless clerk has purloined from his employer goods for his own use. At first it may be a trivial matter, a cheap Rule, Pocket Knife or other small article, but if the practice is not stopped it soon ends by his taking something of more account. Merchants should insist upon being consulted when clerks want goods, and should, if the goods are to be charged or paid for, attend to the matter personally.

MARKING PRICES.

Many merchants lose because of failure to mark goods, thinking they can remember the cost price. The custom of not marking goods is a poor one, for if the proprietor should remember prices himself (which is doubtful), they are very apt to be offered for sale by a salesman who is obliged to guess at the price, and many times does not get cost for the goods. The best plan is to have all goods marked, either on the article, box, package, or by list prices put up in some convenient place.

COLLECTING.

Losses will sometimes occur by not collecting for all goods sold for cash. Several articles may in turn be wrapped up as they are purchased, and the clerk in adding up the amount of the purchase overlooks some of the articles, thus failing to get pay for them. This would not happen so often if each article was itemized separately in figuring up the amount, after which the goods should be counted and checked off.

PACKAGES OPENED.

Many salesmen use goods about a store as if they cost nothing, and new tools are allowed to become soiled, packages of goods opened and part used and part left to spoil, such as Paint, Colors; Putty left to become hard; Glass left where it is liable to get broken, and are wasteful in many other ways. Merchants should insist upon order in the store and should be consulted in regard to the use of new tools and goods liable to become damaged, as all goods of this character, if they are not entirely spoiled, must be sold at a sacrifice.

GOODS AT THE DOOR.

Goods are often stolen when placed outside the store and are neglected until darkness comes on. A practice should be made of bringing in all goods that are set out each day at an early hour.

SHORTAGES.

Loss sometimes occurs because invoices of goods are not looked over by the purchaser. There is willful waste in salesmen throwing in with goods to be fastened a handful of Screws, Bolts or Nails because it is too much trouble to count them.

LENDING TOOLS.

Hardware merchants are sometimes censured because they will not lend tools that persons wish to borrow. Unfortunately he cannot say he has none, for all around, displayed to good advantage, are Saws, Hammers, Axes, Wrenches, Screwdrivers, Squares, Plyers, Bits, Braces and numberless other things which the borrower wants to use, will not injure and will return in a minute! Some of these may be lent, but should be charged to the person and marked loaned, and if not returned to be paid for the same as if purchased.

UNDERESTIMATING COST.

The article of Mica is often sold at a loss as it is bought by weight and sold by the light. A good way to arrive at the cost and selling price is to take each package upon arrival and split it into sheet of the right thickness for use, throwing out any which may be too thin or broken, then weigh and count, dividing the cost per pound by the number of lights.

MEASURE A BARREL.

There are losses from goods bought by weight and sold by measure, such as Oil, and if the dealer will take the trouble to measure a barrel of Linseed Oil he will find it often run short from 3 to 5 gallons if a clean measure of standard size is used. This means a loss to him unless he uses a measure that will hold just the number of pounds he buys for a gallon, which is, I think, 7½ pounds.

The losses that occur from

SHOPLIFTING

by those who visit the store in the guise of customers are considerable. This class of thieves succeed best in stores where there is not much attention paid to customers. The incomer should be promptly met at the moment of entrance and not left to wander about the store from one article to another; by so doing losses in this way would in many instances be avoided.

UNPROFITABLE BUSINESS.

The losses I have mentioned many merchants fail to take precaution against or make allowances for them in their calculations as to their present worth. It frequently happens that when the year expires, inventory taken and accounts made up, the business, which seemed so flattering, is unexpectedly found to be unprofitable, or showing a profit much less than was expected.

Future prosperity will greatly depend upon the discovery of the cause of the discrepancy between calculated and actual results.

MONEY DRAWER.

Many small dealers use the money drawer as their private purse, taking from it whatever cash may be needed, and also take for their use articles kept for sale, and often neglect to make any charge of them. To such dealers, "Waste in the store and how to avoid it" is a subject which I am safe in saying would be of little interest.

MEMORANDA.

W. J. McKay & Co, 51–53 South May street, Chicago, Ill., were visited by fire on the night of March 21 and their establishment pretty well burned out. Their stock, however, was fully protected by insurance, and the fire means simply a removal to new quarters. The concern are located for the present at 399 West Madison street, where they are stocking up to place themselves in a position to promptly meet the requirements of their customers.

Young & Norwood is the name of the concern just started in the stove and furnace business at 114 Lake street, Elmira, N. Y. The new concern will handle Garnet and Peninsular stoves and the Palace Queen and Kelsey furnaces, together with a full line of hollow ware. The firm have a factory at Nos. 154–156 Exchange Place, where they turn out tin, sheet iron and copper ware.

The stove and heating business at present conducted by James Walp on North First street, Lehighton, Pa., changes hands, he having sold out to George L. Geibel of Danbury, Conn. Mr. Walp has

accepted a position with H. M. Norton of Easton, Pa., as superintendent of steam and hot water heating work, and will remove to that place shortly.

PHILLIPS & Co. of Niagara Falls, N. Y., are about to move into their new quarters in the Gluch Building, where they will have one of the largest and finest hardware stores in Western New York. The interior is to be entirely of oak; the offices will be located in the rear of the store, and also finished in oak. A line of the J. L. Mott Iron Works' plumbing samples will be displayed in the rear, next to the offices. They will all be connected so that the operation of each with water may be shown. The back of the samples of plumbing will be entirely of tile wainscoting, while the base of each fixture will be of marble. There will also be arranged 20 sample drawers of finished hardwood, showing samples of real bronze builders' hardware in different finishes, oxidized silver, antique brass, antique copper, nickel plated, old copper, dull brass, polished brass, in fact, all styles of door and window trimmings. The stock of house furnishing goods will be a very complete one. Half of the second floor will be devoted to the tin shop, with seven benches in a direct line with each other, each bench having a window, assuring plenty of light. There will be an 8-foot cornice machine in this department. Back of the tinshop will be the sample room for plumbing goods, steam heaters, stoves, &c. The basement will contain heavy stock and the plumbers' and steam fitters' departments. In this room will be set up two pipe cutting machines. These will both be run by power from an engine connected with the building. The entire place will be lighted by electricity and heated by steam.

J. WALTER DAVIS, West Gardner, Mass., has recently opened a new store, 31 x 100, three stories and basement, heated by steam and fitted up elaborately.

Returned Goods.

FROM THE JOBBER'S STANDPOINT.

While passing through the receiving room a few days ago my attention was directed to a strange medley of articles in the space allotted to returned goods, the accumulation of only two days—average ones at that.

There were small packages, large packages and lots of goods in no packages whatever. As it was quite an interesting conglomeration, I took a note of some of the articles which constitnted it and give it here:

An Iron Pump.
One-half dozen Post-Hole Diggers.
Two bundles Garden Hose.
One coil of Wire Rope.
Three bundles Shovels.
Two boxes Loaded Shells.
One-half dozen Cast Griddles.
A broken Spring Hinge.
A box of Calf Weaners, broken open and some parts missing.
Several packages Carriage Bolts, some of them in very bad condition.

Also several other articles in various conditions.

Being somewhat interested, I inquired the history of the various lots, and learned that the Calf Weaners, the Post-Hole Diggers, the Wire Rope and one number of the Loaded Shells were goods not carried in stock regularly, and had been picked up as an accommodation.

The Pump was specially ordered from the factory, and was returned because the dealer's customer had found one which suited him better before this arrived.

The Wire Rope was ordered and cut too short through dealer's mistake.

The Shovels were sent wrong by one of our order clerks.

The Hose was ordered in good season, but was delayed through negligence of the railroad company, and was not delivered till after close of season, consequently our customer refused it.

The Spring Hinge was not what carpenter wanted, so it was negligently wrapped and sent back, and arrived broken and worthless.

The Cast Griddles were returned for some reason or other—our fault I think—and as they had not been packed at all, they are very badly rusted and will be worthless until they have been repolished.

Thus it was through the entire list. Some of the mistakes rested with ourselves, but more with the dealers. Some of the goods came back accompanied by a terse letter, something like this: "We have retnrned the following goods. Please give us credit, &c." As much as to say, we can't sell them; you must take them off our hands.

This matter of returned goods is a very serious one to the jobbers of the country. At various times action has been taken on it and some good effects resulted.

A year or so ago, a number of the leading houses issued a circular, stating under what circumstances goods might be returned. Some refused to allow anything to be returned which had not been sent wrong through their own mistake; others were rather more liberal. Few adhered strictly to the rules for any length of time. At first they would make exceptions of old and favored customers, who had overloaded themselves, and as one step led to another, the matter is now virtually where it was before the agitation.

This really means a dealer can buy goods, keep them as long as he pleases and, finding them unsalable, return them to the jobber from whom he purchased them. If A remonstrates, the dealer calmly says he will transfer his trade to B, who will accommodate him. A knows this to be true, so generally gives in and is obliged to receive into stock goods which often are shopworn and damaged, and in many instances have to be sold at an actual loss.

This reveals a bad state of affairs which should not exist. The close competition of late years has led many jobbers to make rash agreements with their customers in order to secure their trade. In their zeal to gain and hold patronage they allow themselves to be imposed upon, and often make concessions which are uncalled for and certainly unbusiness-like.

The privilege of returning goods under many circumstances is right enough, but like nearly every other, it is shamefully abused. About the only remedy I can see is to do as the Edge Tool people have done with their warranty—shut down entirely. Nothing but concerted action will accomplish much.

I am glad to say that dealers, such as I have mentioned, are the exception rather than the rule, but they are numerous enough to be quite a thorn in the side of the jobber.

A word to all who may have occasion to return anything to jobber or manufacturer will not be out of place here. ALL GOODS SHOULD BE CAREFULLY PACKED to withstand the rough usage of the transportation companies. I thought while looking over the aforementioned heap what a howl would go up if the very same parties who shipped those goods to us were to receive goods packed as those were, and in the same condition.

Express companies are not responsible for goods merely wrapped in paper so as to hide the contents. Good strong wood boxes should be used for heavy articles. Surely if the jobber is expected to accommodate his customers, they should see to it that the goods are properly packed and shipped, thus doing all they can to insure delivery in the best possible condition. It is no more than fair, to say the least.

SCRAP.

FOR TWO OR THREE YEARS PAST we have followed the proceedings of the Tinned Plate Manufacturers's Association, which, at the time of the revision of the duty on tin plates, was an active agent in bringing about concerted action among those who contemplated going into the new industry. Rumors are gaining currency, however, that affairs with the association are not going altogether smoothly, and in fact there are some so skeptical as to believe that the association has not a very long future ahead of it. It has been pointed out that many prominent concerns are not members of the body, and what is perhaps more ominous, at the recent meetings a number of prominent members have not attended. However, all associations go through periods of varying efficiency, and it is by no means inevitable that the Tinned Plate Manufacturers' Association will cease to be conspicuously useful.

THE NEW SHEET AND TIN MILLS of the Falcon Iron & Nail Company of Niles, Ohio, will be completed so that the fires can be lighted the first week in April. All the machinery is in place and only trivial matters now require attention. The engines were tested on Thursday and found to work perfectly satisfactory. This mill will be one of the finest and most complete ones in the country.

A LONDON EXCHANGE reports that E. Morewood & Co., South Wales Tin Plate Works, Llanelly, have completed their new steel works, and arrangements are being made for the commencement of operations. The new plant includes a three high cogging mill. It is estimated that the new mills will be able to turn out nearly 1000 tons of bars weekly.

A SERVICEABLE PAPER WEIGHT comes to us from John Hamilton, Pittsburgh, Pa., who uses the useful device to call attention to Hamilton's Best American Redipped Roofing Plate, which is described as made by hand by the palm-oil process and fully guaranteed. The paper weight is of glass with rounded edges and corners, and the reference to the firm John Hamilton, Tin Plates, is applied to the bottom in black and white, so as to show through.

Paterson, New Jersey, has 597 manufacturing establishments, representing 73 industries and employing more than $27,000,000 capital. Ten years ago the number was 52 and the capital employed was only about $11,500,000.

STOVE TRADE NOTES.

Advice to Stove Buyers.

Managers of stove houses in Chicago are very properly endeavoring to prevent the World's Fair from interfering seriously with the usual course of their trade. They foresee that many of their customers will visit Chicago during the coming summer, and will arrange to purchase stocks for the fall trade at that time. It is quite natural to suppose that selections can be made to better advantage when the buyer has large sample rooms to inspect than if he merely looks over photographs or through catalogues. Numerous country merchants have but seldom, or perhaps never, had the opportunity to thoroughly inspect actual samples of the goods they order in the stove line, and may think they will be able to do better in this way than by accepting the statement of the silver-tongued traveling man. There is also, perhaps, a deeper impulse in the thought that direct contact with headquarters will give a man better terms or higher consideration than the ordinary second-hand acquaintance through a salesman or by the mails. Chicago managers believe this to be a matter which promises seriously to disarrange their business, and are, therefore, trying to provide against it. Rathbone, Sard & Co. have issued to their customers the following circular letter, and other houses are about to do something in the same line:

To the Trade: We would urge upon our patrons the very great importance of placing their orders this year for their fall stocks with the traveling men, the same as in previous years. We expect and look forward to seeing as many of our friends as possible in Chicago during the World's Fair, and will do all in our power to make the visit as pleasant as possible to them; but, at the same time, we would advise that the visit on us should be a social one, and not a business call, for several reasons:

1. The World's Fair will be worth all your time. It will use up all your strength and energy to properly see it, and you will not care to talk stoves and prices after a day at the fair.

2. Our offices and show rooms will, most likely, be crowded all the time, and we would not be able to give that careful attention we always aim at toward helping you to select a stock of goods.

3. You can better determine in your own office and store what you expect to need the coming season. You will then know what you have carried over, and have all the necessary information to make up an order.

4. The traveler that has always seen you, and knows better than we do the peculiar wants of your trade, will call on you as usual. You will not be able to see him in Chicago, and he may help you in estimating your wants.

5. Our travelers will start out, as usual, June 1, with every information about new goods and prices. They will advise you well in advance when they expect to reach your town. If you expect to be in Chicago at any special time, our travelers will arrange to see you either before or after your trip, if you will let us know when it will be.

6. When you come to Chicago to see the World's Fair, you will probably be accompanied by some members of your family, and you will see the difficulty of giving much attention to business without neglecting them.

We think you will agree with us as to the merits of these arguments, and we hope that you will call and see us, and have your time entirely free from business cares and worries.

The force of the suggestions made in this circular must be admitted by every stove buyer. The World's Fair will be no ordinary occasion of interest for but a few days and to a limited number of people. It will be a source of great attraction for months, and will draw vast crowds from all sections of the country, but more especially from the West by reason of its geographical location. It will readily be seen that, at times, there may be so many visitors calling upon the Chicago stove men that it will be a matter of great difficulty to give them proper attention. Every effort will, of course be made, but to properly handle a constant stream of customers it would be necessary to call in all traveling men, and this would leave those customers uncared for who may be disinclined or unable to visit the Fair. Further than this, experienced salesmen point out the difficulty stove buyers in general will have in deciding exactly what they want, unless they thoughtfully take an inventory of their stock before they leave home and know just what stoves and what sizes they are short.

The Chicago managers emphasize one point, namely, that whether their patrons come to buy or not, a most cordial welcome will be extended and every pains be taken to make the visit enjoyable. They are not trying to diminish the crowd of visitors; but, on the contrary, are endeavoring to shape matters so that the visitors and themselves will enjoy the World's Fair better.

American Stoves Abroad.

The project of sending American stoves to Europe concurrently with the shipments of anthracite coal to that market, which was noticed in *The Metal Worker* some weeks ago, appears to have evoked considerable interest on the other side of the water. One of our London contemporarics, in commenting on the matter, commends it to the consideration of English manufacturers, remarking as follows: "If the closed, or American pattern, stove will sell where our open grates and stoves find no purchasers, it is obvious that our manufacturers should meet the requirements of the would-be buyers by producing stoves in the American style. To do so might possibly be flattering to our friends on the other side of the Atlantic, but 'business is business,' and we must produce what will sell rather than what we ourselves may happen to prefer. It is important to remember, in this connection, that most other European countries have much severer winters than we have in the United Kingdom, and particularly that almost everywhere on the Continent closed stoves of porcelain or metal are in general use. With our facilities for producing and shipping and our nearness to the Continental markets, we certainly ought to be able to compete with the American makers."

Another English trade journal, in referring to the proposed venture, expresses the opinion that, looking to the perfection to which American stoves have attained, and their advantages over the open grate in economy of fuel and superior heating qualities, combined with the comparative smokelessness of the hard fuel used in them, American manufacturers are quite justified in looking to Europe as a possible outlet for surplus production at home. Nevertheless, the journal referred to regards the proposal to extend the American stove trade to the other side of the Atlantic as a singular phenomenon and a proof of "the restless energy and fertility of resource shown by our American cousins, which are such invaluable qualities in forcing open the doors of new markets."

The Woolson Stove.

The *fac simile* of an old stove catalogue which we published in these columns some weeks since, together with an illustrated description of Woolson's stove, has brought out a letter from the son of the maker of the stove which is highly interesting. As there are no doubt many readers of this department of the paper who would like to hear what the writer, H. C. Woolson of Buffalo, N. Y., who is 74 years old, has to say, we make a few extracts, as follows:

I was much surprised to see in *The Metal Worker* of March 4 a cut of my father's old stove. I did not suppose there was any one living who knew anything about it. It was invented in 1816 at Claremont, N. H., but our cuts were burned up, together with the patent papers. I think I can say, without fear of contradiction, that it was the first good working stove ever invented in the United States. It was a good baker and boiler. At the time it was made my father had never seen a cook stove, as there was none in the market. I did not think, however, to ask him until it was too late where he got the idea. There was no pattern maker in those days, and therefore nothing to start on. My brother told me the first stove he made was all sheet iron. He did not like it, so he built the Woolson stove. The sheet iron stove was afterward invented and is made to-day. It was then called the Yankee Notion. It is known now as the elevated oven, but every foundry has its own local name. The Woolson cook was made in New Hampshire, Vermont, Massachusetts, Detroit, Mich., and Cleveland, Ohio. When it was first made the farmers complained that it did not burn half enough wood. When it was laid one side the com-

plaint was that it burned too much wood. I do not know how my father got the patterns made, as there were no pattern makers at that time. The patterns were made of wood, with stays of wood and iron. The molders used to carry them out in the sun and down cellar to get them straight. The doors of the stove had wrought-iron hinges and latches. The stays of the patterns were stopped off when molded. There were some plows of cast iron made at that time. There were a good many stoves produced in New England after 1830. There were no railroads, so the stoves were carted out 40 or 50 miles and left with country merchants to sell on commission. Stanley did more than any one else to improve the stove business, and about the first heating stoves were those which he made.

It is a great pity there are no cuts of some of the old stoves. I think, however, some of them can be found. There were the Wilson, the James, the Premium, the Tenplate, Sixplate, the Box and some other stoves. In 1835 I drove a team to Albany and received a portion of my load at Pratt & Treadwell and a part at Joel Rathbone's. My load was made up of wood Franklin stoves, and I hauled them over to New Hampshire, 110 miles away.

The Stove Trade of the South.

ITS PAST, PRESENT AND FUTURE.

By On-the-Road.

Fifteen years ago a range was almost unknown south of the Ohio River. However, since bituminous or soft coal has been so extensively mined in the South, coal cooking stoves and ranges have been growing in popular favor. The Pennsylvania stove founders, with those who had branches at Baltimore, controlled the market in the Atlantic and Gulf States, while the Ohio River and St. Louis foundries catered to the States bordering on the Ohio and Mississippi Rivers. Pennsylvania stoves, with their peculiar basket grates, took the lead and have held their trade against the Southern-made articles. The new stove foundries of the South have, however, found a ready market for their stoves at home. The great trouble has been the idea on the part of the Southern stove founder to see who could make the cheapest goods regardless of style, finish and workmanship, with disastrous results financially as a consequence. Up to the present time there have been no fine grades of stoves made in the South. Baltimore and Louisville make some Franklins and direct-draft coal stoves for heating purposes of merit and moderate cost. South of these places the entire stove output consists of the cheap step, square cook and plain cast and sheet iron or steel range, with the wood box heating, egg and cannon coal stoves. It seems strange that with all their advantages the Southern stove founders have not attempted the better grades instead of leaving the Northern stove founder the entire field for the finer ranges, cooks and heaters. The Northern manufacturers of stoves need have no fear, for Northern stoves, with their superior get up, style and finish, will continue to find a ready market in the South, and sooner or later some of these Northern manufacturers will pack up, bag and baggage, and move their plants below Mason and Dixon's line, were iron and coal is much cheaper. As to skilled labor, that's another thing. Will our best mechanics go South? Why not? They can live cheaper there and the climate is milder.

A few years ago a Western maker of so-called steel ranges (he called them cast malleable) flooded the rural districts of the whole South with a sheet-flued range, having sheet-iron sides, bottom and oven, with cast malleable fire box and top. The sheet flue gave the range an easy draft. It drew like a house on fire, caught the "wimmin folks," and, it is unnecessary to state, there were "millions in it" to the maker of the range.

The writer has often wondered why stove manufacturers catering to the Southern trade did not "catch on" to the sheet flue long ago, for the Southern trade at least, and adapt it to their line of cast ranges; for nothing so quickly condemns a range in the pitch pine and soft coal sections as an ordinary two-flued range, made North for burning anthracite or hard coal. It is a failure in the soft coal section, though it may be lauded to the skies here in the North. For the benefit of those who do not understand the meaning of sheet flue, I will state that a sheet-flued range has no dividing flue or partition in the end of the range where the fire passes over and around the oven, but allows the products of combustion to occupy the entire width of the oven, passing to the underside, where a short bottom strip or flue keeps the fire along the front of oven to a point where it passes back to a flue bolted on the rear of the range, then up into the stove pipe, instead of going back up over the oven again. Such a flue, be it in a cast range, or in a steel range, or better still, a cast range with a steel oven, is the coming style both North and South, as the sheet steel or iron oven heats quickly, and does not crack and let ashes through, while at the same time it saves those exasperating jobs incidental to a top oven plate. Some of our Northern stove foundries have a line of sheet flue ranges, and they are a pronounced success, even with hard coal; for a range of a given body measurement can be made with a larger oven and sheet flue than the same body of range could with two end flues. Granting that a sheet flue range with 18 or 20 inch oven costs a little more to make than the same size range would cost with two end flues, owing to the fact that the flue on the rear or back of a sheet flued range adds that much more to the cost, the additional outlay for the sheet flue (which really is very little) is more than made up in the added length of the oven. This is owing to the fact that a sheet flue takes up nearly one-half less room than the two flued construction, which must have a wide flue to draw at all, as it requires a much stronger draft than the sheet flue.

I notice that four hole ranges are becoming very popular, and I think they will eventually drive the cook stove from the market, unless we except the cheapest of the coal and wood cooks. The range has as much room on the top, in the oven, on the hearth and shelf, and takes up much less room in the kitchen, while being far more convenient. Ten years from now a cook stove will be a rare sight, to my way of thinking, as cast as well as steel ranges are rapidly taking the place of the old cook stove where coal is used.

PROSPECTS FOR THE FUTURE.

The prospects for a future stove market are nowhere so brilliant as in the South. When once the tide of emigration turns from the West, where the long winter months hold their sway, with the consequent expense and suffering, and the benefits of the glorious climate of the South are more fully understood, there will be a hustle on the part of manufacturers to get there. Few realize the immense quantities of stoves now being sold in the South during a season. The writer has sold bills to some of the retail dealers of the South equal to any in the North, one customer buying nine carloads in one year for the retail trade; another dealer seven carloads; another five, and so on. And it is such a pleasure to do business with a Southerner (no offense, brothers of the North). Yet a Southerner always has that welcome: "Come in, sir. Have a seat, sir." (Gets up and offers you his seat.) No matter how busy, how tired; whether he wants any goods or not, he is always the gentleman. And there is another item that counts with me. The hotels of the South, as a rule, have a comfortable office or reading room, free from the saloon and saloon loafer, where the drummer can read and write in quiet. There are very few hotels up here in the North that have not either a bar in the office or in the adjoining room with open screen doors between, the noise and language making it next to impossible to read or write. And usually, the clerk up here is the bartender, all one and the same person, and when you want any information you have to wait until the barkeeping clerk has first waited on the thirsty ones.

While there are not as many fine goods sold in the South, proportionately, as in the North, yet the larger cities and towns have dealers who carry the latest base burners and large handsome six and eight hole ranges. Many of the largest stove manufacturers of the United States send their best travelers South hustling for trade, and being only too glad to equalize freight rates to most points, which often means an allowance of from 15 to 35 cents per 100 pounds. The South is growing rapidly, and now is the time for the capitalist, the mechanic, and the man of energy and push. Those had better stay at home who have none of these qualities, as it takes every inch a man to go down there and hold his own against the young Southerner of to day.

FIELD FOR GAS AND VAPOR STOVES.

To the makers of gas, gasoline and oil stoves, I would say the field is large and open for improvement. Yet, owing to gasoline being rather high, retailing at from 15 to 20 cents per gallon, mostly at the latter figure, those stoves are not as extensively used as further North. And again, wood is from $2 to $2 50 a cord, and coal from $2.50 to $4 50, which makes gas and oil stoves rather too much of a luxury for a darky to use.

The coming season will likely be the most prosperous the South has ever had. The crisis which had been threatening and which overtook that portion of the country in 1891-2, was caused principally by the ruinous system of long credits. An overstocked cotton market with low prices at the opening of last season kept merchants from placing their orders. However, later in the season, cotton jumped up out of sight, and then it was discovered that there was not only a short crop but a shorter acreage. It was a common thing last season for a merchant to tell the drummer he did not want any stock, as he would have to trust it out. Now stocks are very small, in the stove line especially, and for the past two years the Southern farmer has been raising less cotton and more corn, hogs and potatoes. The scarcity of cotton now in sight and good prices will, necessarily, bring a lively trade this fall. Never were prospects for the stove trade so good as they are for the season of 1893-4, in the North as well as in the South.

HEATING APPLIANCES.

And it will not be out of place to put in a word for the fire-place heater, the hot-air furnace and the steam and hot-water heater. The first two have long been used down there, though not so much as further north. Steam and hot water are the new things, and are being used now in most of the larger, especially public, buildings. But so long as steam or hot water are used to heat by direct radiation, they will never be popular for private residences.

Rathbone, Sard & Co.

now have architects at work on plans for another extension of their plant at Aurora, Ill. A new molding shop is to be added to the foundry, which will double the molding capacity and will make room for about 200 more men. The Aurora Works have been enlarged every year since they were built, and eventually the whole tract owned by the firm will be practically covered by buildings. The Chicago sample rooms are now undergoing re-decoration by way of some preparation for the World's Fair. The walls have been newly papered in a delicate pattern, with a rich frieze of oak leaves, which was the nearest approach to acorns to be found in wall paper stocks. The Chicago branch reports a large range trade this spring, exceeding that of last spring, which in its turn was heavier than for previous years. Special attention is being paid to this branch of their business, no less than six new ranges having been brought out this year, namely, Natural Acorn, a six-hole hard coal range; Magnet Acorn, six-hole, for hard coal; the same for soft coal; Puritan Acorn, six hole, for hard coal; Prince Acorn, four-hole, for wood; Senator, five-hole, for hard coal. These ranges give 14 different sets of patterns for the new catalogue, making what is claimed to be the largest line of ranges on the market. These new ranges are of a distinct type of finish, being built with semi-rectangular lines and panels, yet having all corners curved and softened The new back railing is a particularly fine piece of molding, having an acorn in the center from which open scroll work gracefully curves to either side. Designers this year have had an additional incentive in the approaching World's Fair, at which these goods will be exhibited.

The Thatcher Furnace Co.,

No. 33 Peck Slip, New York city, have issued from the press an exceedingly neat catalogue of warm air furnaces and ranges, which they manufacture. The size of page is sufficient to permit the use of cuts of liberal proportions, together with ample descriptive letterpress. The paper used is of good quality, the printing is well executed and the binding is in colored paper covers. The opening pages are devoted to an illustrated description of the Thatcher tubular furnace, which is furnished in portable form, and also for brick setting. The heater is fully described and directions are presented for setting. There is also illustrated the Thatcher tubular furnace with hot-water attachment, made in two sizes, and arranged for brick work if desired. A new heater which has been added to the company's assortment is known as the Scorcher. It is a steel radiator, low price furnace, having patent triangular grate, dust flue, large feed door and corrugated surface. It also has a diaphragm and radiating ring, which forces the smoke and gas first to the top and then down around the lower part of the ring, thus making two circuits before leaving the furnace. The manufacturers claim that by this method the gases are retained much longer and insure more heat than is generally obtained from furnaces of this class. The dome is of cast iron, made in one piece, while the fire pot is nearly straight and the casings heavy. This heater, we understand, is having a large sale, and the company are confident it will continue to grow in popularity. Several pages in the catalogue are devoted to the Thatcher range, made with fire box on either the right or the left side, as may be desired. The range is made in both portable form and for brick work, and with horizontal or vertical boiler. The ornamentation is neat and attractive without being pretentious. Tables give the dimensions of pit and trench for portable Thatcher tubular furnace; also capacity of warm-air pipes and registers. A few practical hints on warm-air heating constitute a feature of the volume. Several pages at the close are given up to testimonial letters from some of those who have used the goods made by the Thatcher Furnace Company, which show in a striking manner their great popularity. The Thatcher tubular furnace has been sold, it is said, for 40 years in every part of the country, and many thousands are now in use. As an evidence of the popularity of these goods the manufacturers state that among the large real-estate owners the Astor estate have used the Thatcher furnace in their houses for the past 30 years. The company are enjoying a good demand for their specialties, and thus far this year there is a large increase in the volume as compared with a year ago, when their business nearly doubled as against the preceding year.

ODD PLATES.

As our readers are aware, the Molders' Union made a request a short time since for an advance in the wages of stove molders of 15 per cent. At a recent meeting of the manufacturers the matter was considered and a reply sent to the Molders' Union. We understand that the molders are not satisfied with the answer of the Defense Association, and have requested a conference for the purpose of reaching an adjustment of the matter which will be entirely satisfactory to all concerned. The conference is to be held some time the coming week, probably in Chicago.

The many friends in the trade of George F. Dodge, president of the New York Nickel Plating & Mfg. Company, 227 West Twenty ninth street, New York, will be glad to learn that he is able to be at his desk once more and looking after his business interests. He has been confined to the house for something like three months past with a fractured limb, which resulted from an accident at his home. Mr. Dodge, personally, is the most genial of men, and has hosts of friends in Beekman and Water streets.

H. Rendtorff & Co, 16 Lake street, Chicago, Ill., have just issued their sixth annual catalogue of vapor, gas and oil stoves. The leading place is given to the Ideal process, shown with two burners in the top surface and one in the step at the left The company state that it is new in design, has double tubes, the return one encircling the drip tubes, and when in use constantly heating it, and thereby greatly increasing the evaporation. The burner drums are of brass, while the burner caps are easily removed. This stove is made in a number of sizes. The Ideal High and Low Juniors are next shown, together with the official price-list adopted by the Vapor Stove Manufacturers' Association of the United States on August 3, 1892, for the season of 1893. The company also show the Ideal gas range, made in a number of sizes and several modifications, together with the American Junior gas stoves, the American gas heater, the New Beauty oil range, the Royal lamp stove and the Electric oil heater.

A sheet-metal stove with cast iron top forms the subject of a patent recently granted to C. H. Melvin of Minneapolis, Minn. All the plates of the stove are flat in shape and so arranged as to be easily dismounted when required. The plates have flanges on their edges by means of which they are fastened together. Some of the flanges interlock directly with each other, while others are connected by removable hook-like corner pieces, which slide endwise over the joining flanges.

The Stuart & Peterson Company have issued under date of March 20 an announcement to the trade to the effect that they have removed their works to Burlington, N. J., where they have property embracing an area 410 x 200 feet, and a foundry which is thoroughly equipped with modern appliances for conducting their business. They state that they are but 17 miles from Philadelphia, on the main line to New York, and thus enjoy unusual facilities for the rapid handling of goods. With the greatly increased facilities which they now possess, the company feel confident that they will not only retain all their old customers, but add many new ones to their list. While their Philadelphia office is at 1120 Arch street, the company desire all communications addressed to the main office at Burlington, N. J.

The W. J. Loth Stove Company, successors to the Waynesboro Stove Company of Waynesboro, Va., have leased the grounds and buildings, bought the balance of the last named company's property, and have been running full blast since March 1. They are at present giving employment to about 20 hands, and are getting things well into shape. The foundry is 160 x 90 feet, and the mounting shop 160 x 60 feet, two stories in hight. There is a capacity for 50 molders. The company hope to run full in all departments by midsummer. In a very short time they contemplate erecting a warehouse 150 x 50 feet in size and two stories in hight. The works are located in the Shenandoah Valley at the junction of the Chesepeake & Ohio and the Norfolk & Western railroads, and in the heart of the iron and coal fields of Virginia. W. J. Loth, formerly manager of the Southern Stove Works of Richmond, Va., has supervision of the affairs of the company.

The Quick Meal Stove Company, St. Louis, Mo., manufacturers of Quick Meal gasoline and gas stoves, are running to their full capacity, and report a large increase in their business over the corresponding period of last year. As an evidence of the business they are doing, it might be stated that the demand for their gasoline and gas stoves has outgrown the capacity of their present factory, and they are now compelled to equip another factory, some blocks from their present plant, for the manufacture of ovens and ware only. This will give them additional room for the manufacture of stoves, and by this means they hope to keep abreast of their orders.

The Portsmouth Stove & Range Company, Portsmouth, Ohio, are increasing their manufacturing facilities by the addition of machinery, tools, &c., in order to promptly meet the demands of the trade for the wrought-steel range known as the Model. More room is being provided and the force of workmen increased. Special reference is made by the manufacturers to the patent oven door device, which is meeting with great favor at the hands of the dealers. The manufacturers have inaugurated a number of important features in the range named, and upon which, we understand, patents are now pending.

F. A. Root has been appointed manager of the Chicago branch of S. S Jewett & Co. Mr. Root is well known to the stove trade throughout the West, having been on the road for a number of years representing prominent houses, a part of which time was devoted exclusively to the Pacific Coast trade. The Chicago branch is now enjoying an excellent business in steel ranges and in gas stoves. Their line of gas stoves and ranges is now very complete and is proving remarkably popular. A catalogue recently issued gives illustrations and full descriptions of these goods. Large wrought-steel ranges are made, of

great capacity, for hotel use, with eight burners on top and six compartments below, which are respectively used for baking, roasting, broiling, warming and heating water. The water front is in the central lower compartment, with a warming oven above, which is operated by the surplus heat. The whole construction of this range is in the style of the best steel ranges for coal. Smaller steel gas ranges of various sizes are made for family use, also portable gas stoves, combination broilers and griddles for restaurants, double broilers having two chambers, and combination broilers with two cooking holes on top.

GEORGE WILLIAMS and GEORGE A. CUMMER, of Cleveland, Ohio, have patented a form of burner which is claimed to be economical, and which can be used without waste in lighting and starting the burner into action. The burner is said to be self cleaning and a constant generator. It consists in the union of a preliminary vapor generating and combustion chamber, and a mixing chamber, so arranged with the necessary details as to produce the objects sought. Mr. Williams has assigned his interest in the patent to P. J. Cummer of Cleveland.

THE ART STOVE COMPANY of Detroit, Mich., have brought out a very handsome new range, made with six boiler holes and embodying the modern improvements. The decoration involves the use of cast ornaments, nickel, and art tile, all judiciously combined, producing pleasing results. The stove has a very substantial appearance, and the company state that "it catches the popular idea and sells quicker than any six-hole range yet produced." It is known as the New Home Laurel, and is supplied to the trade at a reasonable figure.

F. H. BEECHER, for many years closely identified with manufacturing in the Naugatuck Valley, has been made treasurer and general manager of the H. A. Matthews Mfg. Company, Seymour, Conn. The concern were established in 1890, and their products include Stove Trimmings, Lamp Burners, and Fancy Brass Goods.

THE DURAND MFG. COMPANY of Medina, Ohio, have made some important improvements in their Medina oil stove for the season of 1893. The burners have been enlarged, leaky pipes discarded, and other parts simplified and rendered safe to handle and easy to operate, without smoke or odor. The stove for this season is known as the Oil Queen, in order to distinguish it from the Oil King of 1892, which was provided with a smaller burner and wick.

THE ELECTRIC OIL STOVE COMPANY of Homer, Mich., are vigorously pushing the sale of their Electric oil stoves, for which many claims are made. They refer especially to their new wick raiser and rewicking attachment combined as being the simplest and most complete device for the purpose ever applied to a stove. Their lamp goods are constructed with brass oil reservoirs, and are guaranteed not to leak. The base and top castings are nickel-plated and highly polished, thus giving a very attractive appearance.

THE NATIONAL ASSOCIATION OF STOVE MANUFACTURERS expected to hold their annual convention in Chicago this year. In view of probable difficulty in securing hotel accommodations, on account of the World's Fair, there is a movement on foot to change the place of meeting to Detroit. The suggested change is being very favorably considered by the members, so far as expressions of opinion have been obtained.

H. LEONARD WILTON of the Art Stove Company of Detroit, Mich., has recently started on an extended tour through the Western States. It has been the custom of the company for some time past to have one of their officers call upon the larger dealers at least once a year, and Mr. Wilton is now making one of these annual calls.

J. A. COMSTOCK & Co. of Kansas City, Mo., send us a copy of a neat catalogue of 80 pages relating to stoves, ranges and heaters which they handle. The line includes the Economy six-hole range for soft coal, hard coal or wood; the Noxol, also for coal or wood; the Irving, Fidelity and Dome ranges, together with a line of cook stoves, made under such names as Prize Economy, Golden Economy, Bessemer, Kaw and Omega. The wood-burning constructions are represented by the Eureka and Economy ranges; the American, Alpine, Economy, Stately, Iroquois, Magnolia, Sunrise and Mascot cook stoves. There is also shown a line of steel ranges. The heaters are represented by the Art Rosemont, made in several styles and sizes; the Radiant Gem, Social, Economy, Tulip, Motor, New American Oak, Garnet, Live Oak, Topic, Carbon, New Banner Cottage, Redwood, Solar, Tribunal, York and Duke. The pamphlet closes with a net price-list of cast-iron hollow ware, a few remarks to dealers, and the statement that, in addition to their large line of stoves, the firm carry in stock a full assortment of pieced tinware, stamped ware, galvanized iron, and black sheet iron, and all other goods used in connection with stoves.

THE MUCH-MOOTED PROJECT of a joint pavilion for the entire stove exhibit at the World's Fair has been abandoned. The different manufacturers will erect booths or inclosures according to their own ideas. It was found too difficult a matter to adjust the expense properly among the many exhibitors interested.

THE FULLER-WARREN COMPANY'S Chicago sample room will be greatly improved in appearance after the renovators get through with it. A metal ceiling has been put in, and the fittings generally have been overhauled. With a line of brand-new samples on the floor, including the Fuller & Warren Warming and Ventilating Company's school furnaces, a very attractive appearance will be presented to World's Fair visitors this summer.

CRIBBEN, SEXTON & Co. are not to be outdone by their competitors in the Chicago stove trade, but are making vigorous preparations for the proper entertainment of visitors to the World's Fair city. Their sample room has been thoroughly overhauled and brightened up, and the display of stoves and ranges will be a whole fair in itself.

A bill has been introduced by the Government into the British House of Commons, dealing with accidents in certain specific works. The aim of the measure is that employers may be compelled to give notice to the Board of Trade of any mishap occurring at their works which incapacitates a person from following his employment. It also gives power for investigation by an official of the Board of Trade into the cause of any disaster which may have happened. The bill has been called for primarily by the frequent casualties which have occurred at the Manchester Ship Canal Works. Some 1200 accidents involving injuries to workmen have taken place there, in addition to 130 accidents of a fatal character.

There are now about 15,000,000 bushels of wheat in store at Chicago and 10,500,000 at Duluth. The wheat in sight at lake ports approximates 4,000,000 bushels, which is above the average and will be an important factor in making strong freight rates on the lakes.

Prize Competitions

$25.00.

Prize Competition No. 18.

SUBJECT:

The Extent to Which Merchants Should Devote Their Attention to Outside Interests.

This competition is designed to call out views as to the desirability of merchants taking prominent part in the local interests of the place and as to how much time can thus be spent to the advantage of their business. Among these interests may be mentioned school matters, industrial development of the town or city, elections, boards of trade, railroad projects, good roads, manufacturing interests, public improvements such as water works, sewerage, gas and electric lighting, street railways, &c. Practical examples will add interest to the discussion. It will probably be generally agreed that attention to such matters increases the influence of the merchant in the community, and in that and other ways contributes to the success of his business, while at the same time it is a question as to how much time should be given to them. The subject is thus a broad one, covering the question as to the position which the merchant should occupy in regard to the public interests of the community.

This competition will remain open until April 22, 1893.

Those intending to compete are reminded that it will not be necessary to write long essays, but that comparatively brief and business-like answers will be favorably regarded as meeting the purpose for which these competitions are announced.

The following prizes will be awarded:

First prize	$12.50
Second prize	7.50
Third prize	5.00

The prizes will be awarded for answers which in the judgment of the committee of award are most suitable for publication and of the most general interest. We reserve the privilege of extending the time on any competition in case the contributions received are not of sufficient number or merit for the committee to award prizes. These competitions are open to every one, and it is hoped that there will be a general response from business men. We shall have the privilege of publishing any or all of the contributions received.

Replies are to be received not later than April 22, 1893. They should be addressed as follows:

DAVID WILLIAMS,
96-102 *Reade street,*
New York.
Prize Competition No. 18.

The committee to whom the contribu-

tions in Prize Competition No. 4 were referred have awarded the prizes as follows:

First Prize to BERNARD B. NEAL, New York.

Second Prize to J. E. BACKENS, Eureka, Cal.

Third Prize to G. B. KORBETT, New York.

Other Competitions which have closed are now in the hands of the Committees of Award, who are giving careful attention to the claims of the different contributions. From the number of these and the evident merit of not a few of them, we are assured that a great deal of valuable information and suggestion will be put at the disposal of the trade.

The Weekly Prize Competitions noted below are now before our readers and remain open until the dates named:

No. 15. Closing April 1.

Suggestions in Regard to the Sale of Athletic and Sporting Goods.

No. 16. Closing April 8.

Three or More Rules to be Observed in Buying.

No. 17. Closing April 15.

How Merchants Should Treat Traveling Salesmen.

No. 18. Closing April 22.

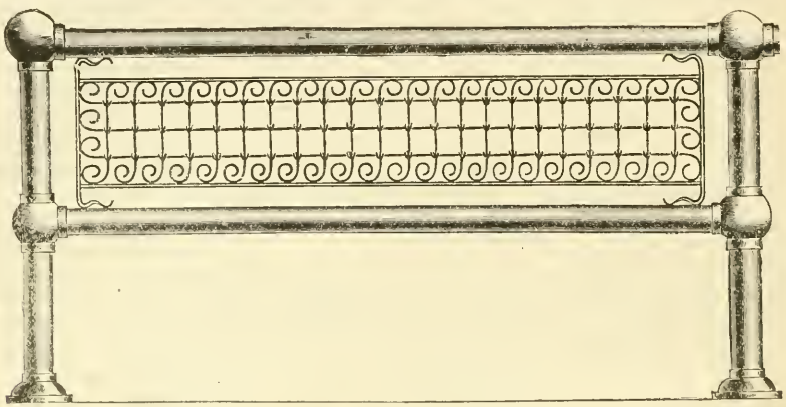
The Extent to Which Merchants Should Devote Their Attention to Outside Interests.

Another subject will be announced in our next issue.

It is acknowledged, observes an English gas exchange, that the best way of "earthing" lightning conductors is to connect them with gas or water mains; but it is important that the connection should be good, in order that there shall be no trouble at this point in the event of a heavy discharge. Herr Müller of Darmstadt sends to the *Journal für Gasbeleuchtung* a description of an arrangement of this kind, which is recommended as cheap, reliable and easily applied. The end of the conductor is wrapped once round the main pipe, and secured in place by means of a clamp made in halves and bolted together. The conductor passes up through a hole in the upper half of the clamp. When this is fixed, the whole thing is packed round with clay, and run in solid with lead, after which a coating of asphalt is applied to make a neat finish. The connection has been tested by Dr. Kittler, who found the resistance to be less than $\frac{1}{1000}$ ohm. It is, of course, wholly a question of obtaining and preserving, between the lightning conductor and the pipe, a clean metal connection large enough to carry off any charge that the conductor itself can withstand.

Exposition Railings.

The Crane Company, Randolph and Jefferson streets, Chicago, are devoting considerable attention to the manufacture of railings for the inclosure of exhibits at the coming World's Fair. These railings are made from 1½ to 2 inch pipe, and, together with the fittings and trimmings, are finished in four styles, namely, plain black for painting in any color, antique copper, polished steel and heavily plated brass. A variety of patterns has been designed to meet the views of purchasers, covering very plain forms, with single rail, a little more expensive with two rails and quite elaborate designs with ornamental panels. A section of the latter is herewith illustrated. Gates are made in a number of styles, such as a lifting bar, a telescopic tube or swinging on hinges. The company have issued a circular describing these railings, also stating that through an exclusive concession they have established on the exposition grounds a branch store and shop, where they can cut, thread and prepare any style of railing for erection.



Exposition Railing.

The Canning Industry.

The importance and economic value to the country at large of the canning industry has been constantly insisted upon, and with evident results for good, judging by the large yearly rate of increase reported in the number and capacity of canneries. In an article on this subject in the *Manufacturers' Record*, special attention is drawn to the facility of the canning operation and the small outlay necessary for setting up a factory. The preparing process requires no particularly expert knowledge beyond that possessed by any capable house wife who is used to cooking and preserving fruit and vegetables in her own kitchen. It can be easily learnt by any ordinarily intelligent person, while the manipulation of the cans—capping, tipping and sealing—requires but the most elementary acquaintance with the use of the soldering iron on the part of the operator. The article above referred to goes, in detail, into the cost of establishing and running a canning factory, showing with what a small investment of capital a canning plant may be started. For example, a plant having a daily capacity of 2000 cans of 3 pounds each, can be equipped with all necessaries for $100, exclusive, of course, of bricks and building. Similarly one for 3000 3 pound cans would cost $150; 4000 cans, $200; and 10,000 cans, $300. Once started the only outlay will be the payment for material and labor; the latter expense being calculated at $25 daily for a plant packing 3000 3 pound or 4000 2 pound cans. The wide field of agricultural products and fruits which can be treated by a canning factory ensures constant work pretty well all the year round, especially in the South, where the industry appears to be making long strides. Canned tomatoes—of which nearly 3,500,000 cases were packed in the United States last year—peas, beans, corn, peaches, pears, plums, berries, and an infinite variety of vegetable food, not to speak of meats and fish, find a ready market throughout the world, while the encouragement the canning industry gives to certain agricultural and other industries upon whose products it depends is considerable.

Soldering Metal for Aluminum.

An ingenious inventor in Norway claims, says the London *Plumber and Decorator*, to have realized the much-felt desideratum of a soldering metal for aluminum. It consists in combining cadmium, zinc and tin, mixed in substantially the following proportions: fifty parts cadmium, 20 parts zinc, and the remainder of tin; the zinc being first melted in any suitable vessel, the cadmium is added to this, and then the tin in pieces—the mass to be well heated, stirred and poured. The proportions of the various ingredients may be varied in accordance with the use to which the substance is to be put. Thus, where a strong and tenacious soldering is required, a large proportion of cadmium may be used; where great adhesion is desired, a large proportion of zinc would be essential; and, in case of an attractive and durable polish being sought, a greater per cent. of tin would be called for. The alloy produced in this manner—independent of its use as a solder for aluminum—is light in weight and capable of taking a very considerable polish; and, though as a soldering metal it can be satisfactorily employed for a variety of the ordinary metals, experience shows it to be of special adaptation to aluminum.

TRADE REPORT.

The Iron Market.

Various conditions have prevailed in the Iron market in different sections of the country during the past week. While there has been a demand and a somewhat stiffer market in some locations, the prevailing condition of trade in Iron and Steel is conservativeness, which manifests itself in a disposition to place orders only for immediate requirements, irrespective of any advancing tendencies in prices. The Eastern markets show very little change from last week, although on the whole the feeling is probably a shade firmer. The continued firmness in Steel and in Steel Stock has a sympathetic influence on the general market, although as yet without developing any actual change in prices. The next ten or fifteen days ought to test the situation, but for the present consumers are not placing much reliance in higher prices. Purchases, therefore, while fairly liberal, are not in marked contrast with the supply, consequently prices remain about on the same level as they have been for some time past. On general principles one might be inclined to look for a slight advance all along the line, but that point has not been reached yet, and until it becomes an actual demonstration it will be very hard to convince consumers that the market is going higher. At the same time, while they are open to conviction, they are not inclined to give much aid in bringing it about. The advance in Bessemer, and in Steel stock generally, has not aroused any great enthusiasm, because they doubt if it can be maintained. Prices are higher on paper, but so far as this vicinity is concerned they are not higher on actual transactions, and nominal quotations do not make much impression. It is admitted that the market may take a sharp upward turn, but when urged to place orders the general reply is that "we will risk the delay; if prices are going higher we shall be entirely satisfied to pay the advance." It therefore simply resolves itself to a question of supply and demand, which at present are evenly balanced, with perhaps a slight tendency toward scarcity at the inside figures, but at every 10¢ or 15¢ ℔ ton beyond that there are evidences of an increasing desire to market liberal quantities.

In Western markets, while the Iron trade appears to be in a mixed condition, the volume of business is steadily increasing, and the prospect for further trade brightens as the spring advances. A more confident tone pervades business circles generally, and some notable instances of advanced prices are reported, and yet at the same time there are sellers at very low rates, showing that some concerns are still exceedingly anxious for business. It is possible that the good volume of trade may in time enable these weak brethren to get in better condition. But as some withdraw others are ready to take their place. The advances in raw material made at Pittsburgh are looked upon as the most encouraging feature of the situation, and have played an important part in contributing to the better feeling.

Southern markets show some increase in the volume of business in Pig Iron during the week, and the general tone of the market is more confident; prices are not any higher for Southern Iron for immediate delivery, but there is less disposition to sell for long forward delivery, except at an advance of 25¢ ℔ ton; and, in fact, the leading furnaces discourage such orders, for they anticipate that Iron will be worth more money when the time of delivery arrives. There have been sales of several lots of 1000 tons for short forward delivery, as well as numerous carload lots, and buyers insist upon prompt delivery, for it is evident that they are leaving a narrow margin in purchasing over their present necessities, and stocks in consumers' hands are reduced to the lowest terms. The largest sale was 5000 tons of Gray Forge at $8.25, f.o.b. Birmingham, deliverable in equal quantities each month for five months. Small lots of this grade are selling at $8 for immediate shipment. Mottled Iron is in light supply and is difficult to buy for any less than Gray Forge.

The week has been uneventful in the New York Pig Iron market, no movement of any consequence having taken place. Northern brands are quoted at $14.50 @ $15.25 for No. 1; $13.75 @ $14.50 for No. 2, tidewater. Southern Iron, same delivery, $14.25 @ $14.75 for No. 1; $13.25 @ $13.75 for No. 2 and No. 1 Soft.

At Philadelphia stocks of good Pig Iron are in small compass, so that prices are steadily held and have a strong undertone. Consumers claim to be able to buy at concessions, but when it comes to a point they usually take their regular brands in preference to those that are nominally lower. It is inferred, therefore, that, quality considered, current quotations are about as low as they are likely to be, and that buyers are not inclined to experiment with new brands, unless at larger concessions than are now available. Several furnaces that furnish considerable Iron to this vicinity are temporarily out of blast, and as others are well sold up, there is an impression that it will result in a scarcity of good Irons after a while, and that in any event prices of such cannot be lower. Southern brands are not specially abundant, but at quoted rates there is sufficient for all present requirements, so that prices just about hold their own. In fact, the entire situation appears to be one of easy uniformity, whatever disparity there is being due to quality, necessity for realizing, or some feature not directly connected with the market. General quotations are about as follows for Philadelphia and equivalent deliveries, with 25¢ to 50¢ less on Southern brands at Harrisburg and intermediately to Baltimore:

American Scotch, No. 1X.....	$16 25	@	$16.75
American Scotch, No. 2X.....	15 25	@	15.75

For the week under review the amount of Bessemer Pig Iron changing hands at Pittsburgh was considerably less than for the preceding week. This was due principally to the fact that buyers have covered their immediate requirements, while those who have not bought very largely ahead are buying in small lots and taking their chances on the future of the market. The heavy sales of Bessemer made during the past month have placed consumers in a better position as regards supply, and the scarcity of prompt Iron has disappeared to some extent. One of the largest consumers in this district, who bought very largely within the past month or six weeks, is reported as having asked some of the shippers to defer shipment for a time, and this will place some Iron on the market that otherwise would not have been available. The closing of the Duquesne plant for a month or six weeks will decrease consumption materially during the time the plant is off. Prices during the week were maintained on a basis of $14, Pittsburgh, with several buyers claiming to have been offered Bessemer at $13.90, Pittsburgh. We quote as follows:

No. 1 Foundry.....	$13.75	@	$14.00,	cash.
No. 2 Foundry.....	12.75	@	13.00,	"
Charcoal Foundry No. 1....	17.00	@	18.00,	"
Charcoal Foundry No. 2....	16.50	@	17.00,	"
Bessemer Pig.....	13.90	@	14.00,	"

Three sales of Bessemer, aggregating 2300 tons, have been made for April and May shipment, at $14, Pittsburgh.

Quite a good business has been done at Chicago the past week in local Coke Iron. Buyers appear to have gained more confidence in the stability of prices and little difficulty is now found in getting advance of say 25¢ ℔ ton as compared with rates current a couple of weeks since. The situation would be very much better if it were not for the low price now being quoted by Southern producers. Soft Irons are in pretty good demand, but sales have been made at the lowest rates ever known here and there seems to be no immediate prospect of an advance. Southern Foundry grades appear to be in

greater supply than Soft Irons and, if anything, are a little weaker, and special efforts have been made to push sales. Consumers realize that they have a golden opportunity in being able to buy at the rates now prevalent, and it is likely that the next few weeks will see a great deal of business in this direction. Southern makers, however, are not disposed to sell at these terms on very long deliveries. Lake Superior Charcoal is in some demand, but only in small lots. Large consumers are deferring their purchases until later in the year. There is as yet very little doing in Iron Ore here and it is probable that not much will be done in this line for two or three weeks. We revise our quotations as follows, cash, f.o.b. Chicago :

Lake Superior Charcoal	$16.50 @ $17.00
Local Coke Foundry, No. 1	13.75 @ 14.25
Local Coke Foundry, No. 2	13.00 @ 13.25
Local Coke Foundry, No. 3	12.75 @ 13.00

The foundries in the Cincinnati district appear to be full of work, and the melting of Iron in the aggregate is apparently larger than it was a year ago. There is not much Charcoal Iron selling, but there is a good demand for No. 2 and No. 1 Foundry Iron. The sales for the week aggregate about 25,000 tons of all kinds of Iron. Many of the Southern furnaces are sold so far ahead that they will take no more orders for early delivery. Quotations unchanged.

Foundry.

Southern Coke, No. 1	$13.25 @ $13.50
Southern Coke, No. 2	12.00 @ 12.25
Southern Coke, No. 3	11.25 @ 11.50
Ohio Soft Stone Coal, No. 1	16.00 @ 16.25
Ohio Soft Stone Coal, No. 2	15.00 @ 15.25
Mahoning and Shenango Valley	14.75 @ 15.00
Hanging Rock Charcoal, No. 1	19.00 @ 19.25
Hanging Rock Charcoal, No. 2	18.00 @ 18.50
Tennessee and Alabama Charcoal, No. 1	15.50 @ 15.75
Tennessee and Alabama Charcoal, No. 2	14.50 @ 14.75

Metal Market.

Copper.—All the strong points that have been brought forward of late in the shape of reduced output of Copper, and prospective increase in the demand, seem to be barren of anticipated results. In any event, the larger demand is extremely slow about materializing, while the offering is strongly suggestive of some anxiety on the part of sellers. Certain it is that 11¾¢ has become a common selling price for Lake Superior Ingot and that business has been effected "on the quiet" at a shade less in more than a few instances. In fact, 11⅝¢ would appear to be very close to current market value for spot or near future deliveries. Speculators have offered August delivery at as low as 10½¢, without result in the way of attracting custom from any quarter. Casting Copper is not offered with the same persistency, but the fact has been brought out very plainly that buyers for round lots have only to bid 10¾¢ to be accommodated, although the nominal quotations are 10¾¢ @ 11¢ for ordinary quantities. Taken as a whole, the market seems to be disappointing and not without signs that the intended effect of reduced production in this country and Europe is, for the present at least, offset by the indifference of buyers. The possibilities for a large demand for Copper for electrical purposes exist, but, like other prospective outlets, this turns out to be rather disappointing up to the present time, and it is only in sporadic cases where immediate delivery was involved that sellers have secured the nominal quotations.

Pig Tin.—The finest work engineered by the "bulls" in the speculative arena to sustain or advance prices has been ineffective. As a matter of fact, the weight of heavy supplies seems to have outbalanced manipulation as a factor in regulating prices, and the outlook is shrouded with more doubt than it has been at any time since the McKinley duty boom was started in motion. Surface appearances are that distributors and consumers have been rather hasty and that the burden of heavy stocks on spot and about and afloat has become a little wearisome. Certain it is that the premium on spot stock has disappeared in this market, although nominally about £3 ℔ ton in London. April contracts are fully 15¢ ℔ 100 lb lower here at the present time than they were a week ago and 10 ton or larger lots have been offered in the interior as well as here at that reduction, without stimulating business. The Banca and Billiton sales in Holland realized prices somewhat below previous valuation and indicated that Continental as well as English markets are somewhat unsettled.

Pig Lead.—Some sales were made early in the week at 4 05¢ for good-sized lots and 4.07½¢ for single carloads, but the market has become quieter, and, with the turn in demand, there is some softening of values. That is to say, sellers at 4.05¢ are more numerous now than were buyers at that time, while the demand is extremely tame. It is not clear that supplies at primary points are heavier, but the offering for last half of April and later shipment is freer, indicating that prospects are favorable for a liberal supply of metal in the near future.

Spelter.—Ten car loads or more of Western Spelter have been sold for early shipment at about 4.30¢, delivered in the East. The demand has slackened during the past few days, however, and sellers are now more numerous than buyers at that price. Nothing new has come to light regarding the proposed combination of producers, and at present negotiations for sale of Spelter are carried on as though nothing of the kind had been contemplated.

Antimony.—Dealings have been moderate and prices are without radical change although rather soft. Current quotations are 10¢ @ 10¼¢ for Hallett's, 10¼¢ @ 10½¢ for LX and 10½¢ @ 10¾¢ for Cookson's.

Tin Plate.—In roofing sizes of Terne Plates there has been rather more business, but not enough to have any decided bearing upon values. Otherwise the market has presented a tame appearance and orders for both prompt and future deliveries have been filled at practically the same prices that ruled a week ago. Business with retailers remains in an unchanged condition, with no change in prices.

Coal.

The Anthracite Coal trade is slumpy and weak, notwithstanding the lower schedule of prices, and there are signs of growing dissatisfaction with the general management, some of the operators thinking that on the part of a prominent leader at the agents' meeting there is too much dictation, which may result in open warfare, perhaps, within a month. The independent coal miners are said to derive considerable advantage from their opportunity. It is certain that there is some cutting—that nobody, in fact, expects to realize more than $4 for Stove, though the schedule says $4.15, and other sizes are shaded in proportion. Pea and Buckwheat are scarce and firm. Operators deny that the new schedule is received with satisfaction, claiming that, on the contrary, it excites discontent and invites demoralization. The best that can be said is that the market absorbs a fair amount of Coal, but a period of continued weakness is not improbable as the spring advances, even if accompanied by activity. Respecting lower railroad tolls, the Philadelphia *Ledger* says that if the rate of tolls from the Schuylkill region is made $1.70, the rate from the Lehigh will be fixed at $1.75, and from the Wyoming district $1.80. The total shipments to market for the week ending March 18 were 766,126 tons, compared with 574,037 tons in the corresponding week last year, and for the year to that date, compared with the corresponding period of 1892, there is an increase of 368,570 tons.

Financial.

There is no special animation in business circles, due mainly to questions concerning the currency, though a tempestuous March and bad roads, interfering with the ordinary course of trade, have had much influence. Conjectures recently rife respecting the possibility of gold going to a premium are at least temporarily dismissed, the supposition being that the United States Treasury is no longer embarrassed by a lack of gold, the foreign demand having diminished, while bankers in all parts of the country readily surrender gold in exchange for notes. Henry Clews says: "The large outflow of currency to the West and other points which came so unexpectedly has suddenly abated, and the indications now are that, so soon as we have turned April 1, money will flow back to this center in considerable volume. Borrowers, therefore, feel assured that, so far as concerns the local money market, it is now only a matter of bridging over for the next two weeks; which is an assurance worth much as a contribution toward confidence." The fact is recognized, however, that the causes of the recent gold drain are still operative, and are liable to become intensified, should there be no improvement in foreign trade conditions and no definite prospect that the accumulation of silver shall cease. With low rates of interest in Europe foreign capitalists have no motive for withdrawing their invest-

ments from this side so long as confidence is not disturbed. A special feature this week has been a fall in the price of bar silver in London to 37 1/8 pence ℔ ounce, the lowest on record, caused by rumors that the Indian Government will close the mints against silver. Two notable events closely related to business interests are the decisions rendered by Judges Ricks and Billings, of Toledo and New Orleans respectively, the former holding that railway employees and railway officials are alike amenable to law and cannot sacrifice public interests in seeking their own advancement, while the latter discusses fully the rights of labor unions and finds that the merchants in New Orleans who asked for injunctions against combinations in restraint of trade are entitled to them.

The settlement of the cotton strike in England and the coal miners' strike in the Monongahela Valley had little effect, except as the former event caused a decline of several points in cotton quotations, due to heavy selling orders telegraphed from the South to Liverpool. Spot cotton was steady with a good export demand. Coffee was dull and slow. Coal was weak and irregular, and there were indications of dissatisfaction with trade managers. Sugar was stronger and advanced all round. Dry goods jobbers report that the condition of the market and of manufacturing are the best witnessed in many years. The mills of every description are full of orders. Wheat declined between 1¢ and 2¢ ℔ bushel, with nearly a corresponding reduction in value of corn and oats. Pork products were also lower.

Chicago Report.

Scrap.—Cast Scrap is in very good demand, but Wrought grades are comparatively quiet. Dealers' buying prices are as follows:

	Per net ton.	Per ℔
No. 1 Wrought Scrap	$13.00	....
Machinery Cast	10.00	....
Malleable Cast	7.00	....
Stove Plate (free of burnt)	7.00	....
Burnt Iron and Grate Bars	5.00	....
Sheet Iron and Hoops	4.00	....
Plow Steel and Breaking Stock	8.50	....
No. 2, such as Shovels, Hoes, &c.	4.50	....
Old Boilers—whole (Iron)	8.00	....
" (Iron)—cut in single Sheets and Rings	12 00	....
Old Gas-Pipe and Boiler Tubes	9.00	....
Cast Borings	5.00	....
Turnings	6.00	....
Horseshoes	12 50	....
Copper Bottoms	....	8¢
Copper Clips and Heavy	....	9¼¢
Heavy Brass	....	8½¢
Light Brass	....	4 ¢
Pipe Lead	....	3 ¢
Tea Lead	....	2¾¢
Zinc	....	3 ¢
Rubber	....	2¾¢

Anthracite.—Carload lots of 12 net tons are still quoted as follows:

	Egg, Sto. and Ch.	Grate.
Chicago, Ill	$5.85	$6.10
Milwaukee, Wis	5.85	6.10
Kansas City, Mo	9.05	9.30
Council Bluffs, Iowa	9.05	9.30
St. Joseph, Mo	9.05	9.30
Leavenworth, Kan	9.05	9.30
Omaha, Neb	9.05	9.30
Burlington, Iowa	7.35	7.60
Des Moines, Iowa	8.80	9.05
Davenport, Iowa	7.15	7.40
Dubuque, Iowa	7.15	7.40
Madison, Wis	7.35	7.60
St. Paul, Minn	8.35	8.60
Lincoln, Neb	9.20	9.45
Sioux City, Iowa	9.05	9.30
Aberdeen, S. Dak	9.10	9.35

Colorado Anthracite.

COLORADO FUEL & IRON COMPANY.

Denver	$8.00
Pueblo	8.00
Colorado Springs	8.00
Leadville	8.00
Cheyenne, Wyo	10.00
All points between Denver and Missouri River	9.35

CONDITION OF THE

Hardware Trade.

OUR REPORTS WITH SUBSTANTIAL unanimity refer to the volume of business as very satisfactory, and in some lines, among which Heavy Hardware and seasonable specialties may be mentioned, is especially active. With the advance of the season there is a general quickening in the demand, which has, however, been retarded somewhat by severe weather. Retailers are evidently placing orders carefully and are indisposed to purchase beyond their requirements, but throughout the country the prevailing prosperity and the prospect of excellent trade during the summer are having their effect on orders. In a few lines prices are slightly stronger and the market is characterized by a better tone than for some time. Quotable changes in price are, however, few and unimportant. There is more or less complaint in regard to collections, which are not as easy as could be desired, and in some sections are particularly slow.

Advices from Chicago.—Better weather in part of this section has stimulated the demand for Shelf Hardware to some extent. The business of the past week was certainly larger than the previous week, but there is still plenty of room for improvement. The roads are in exceptionally bad condition throughout the Northwest, and even with good drying weather considerable time will be required for them to get in good shape. Snow storms have also been prevalent during the past few days, and last week traveling men were again snowbound in some localities, which is rather a setback for this time of the year. The prices of goods are hardening in quite a number of instances. Stamped ware is dearer and staple goods are steadily moving upward. The strike in the Chicago carriage factories is affecting the trade of the Heavy Hardware jobbers, who have been enjoying an excellent demand from that branch of business. Collections are still bad and the prospects are not bright for an early improvement. It is expected that as soon as farmers are able to get in the fields they will be so busy seeding that they will be disposed to attend to nothing else for some little time.

Notes on Prices.

Cut Nails.—The Cut-Nail market is steady and without specially new features. Trade is continuing in very satisfactory volume, the aggregate of transactions being large. The market in the matter of price is represented by the quotation of $1.20 for carload lots at mill and $1.40 for similar lots on dock, New York. The new card is being adhered to remarkably well and is used with general satisfaction by the trade. While there is a disposition to regard orders with a high average with exceptional favor, the understanding that quotations are to be made without regard to average is very well carried out by the mills.

Advices from Chicago.—A very fair trade is reported by local manufacturers. They now quote $1.40 on account of the lower freight rates from the East after April 1, but express themselves very confidently as to their ability to maintain this price, notwithstanding the report of some cutting in other localities. Small lots from stock are held at $1.50.

Wire Nails.—The Wire-Nail market is in what is generally regarded as a very satisfactory condition, the volume of business being heavy and dealers evidently purchasing freely in confidence that Nails bought at ruling prices are a safe purchase. Quotations are on a basis of $1.50, f.o.b. factory, with Cleveland as the point of equalization for the West and Pittsburgh for the East. This quotation is maintained with exceptional firmness, and it is thought not unlikely by some well-informed parties that higher figures will be named in the near future. Small lots from store in New York are quoted at $1.75 to $1.80.

Advices from Chicago.—Manufacturers report a very good demand from the large trade, and in numerous instances very prompt shipment is wanted, showing that stocks are being run quite close. Prices are maintained very firmly, as is shown by the inability of manufacturers to purchase odd sizes from each other at anything less than the current market quotation. Inquiries are coming forward from large buyers who were supposed to have covered their wants for the greater part of the spring trade. The demand bids fair to continue in full tide longer than usual. A reduction of 2 cents per hundred in freight rates from Ohio mills goes into effect on April 1, but if the volume of business keeps up it is not likely that the reduction will be made on prices here, which are now $1.65 for carload lots and $1.70 for small lots from stock.

Barb Wire.—The Barb-Wire market is firm on a basis of $2.45 to $2.50 for Four-Point Galvanized in carload lots at mill. The volume of business is large and the condition is, on the whole, very satisfactory to the manufacturers. Anticipations are expressed that the year's business will be exceptionally heavy, some indications pointing to an unusually large demand. Carload lots on dock in New York are held at $2 65 to $2.70. There has been no recent change in the price of small lots from store.

Advices from Chicago.—Manufacturers note a steady improvement and expect a very heavy trade as soon as the weather improves throughout the Northwest. Jobbers are now in line, quoting prices no lower than those of manufacturers. This has given a better tone to trade, as it shows that jobbers' stocks are being worked off. Small lots are now selling at $2.30 for Painted and $2.70 for Galvanized. Carload lots are quoted at $2.20 and $2.60 respectively.

Tackle Blocks.—The market is very irregular and prices are probably lower than ever before, with a tendency still downward. This condition of things affects not only the Iron Strapped Blocks, but also the fancy and patent Blocks to some extent. This line as a whole is in a very unsatisfactory condition and characterized by a good deal of irregularity owing to the very animated competition between the manufacturers.

Carriage Bolts. — Common Carriage Bolts are in a somewhat more satisfactory condition than a few weeks ago. There is evidence of a reaction from the extreme prices which have lately ruled and some of the lowest quotations have been withdrawn. The market is still somewhat uneven, but there is an evident improvement in its tone. The volume of business is large and many of the manufacturers are full of orders.

U. M. C. Loaded Shells.—The Union Metallic Cartridge Company, Bridgeport, Conn., have issued a revised price-list of their New Club, Smokeless and Trap-Loaded Shells, in which some additions are made to their former line on which the list prices remain unchanged. It is subject to a discount of 40 and 10 and 10 per cent. In connection with it they issue a circular under date March 15, in which they give information in regard to the principles on which the Shells are loaded.

Steel Mortar and Brick Hods.—These goods are put on the market by the Avery Steel Mfg. Company, Chicago, for whom Wm. H. Jacobus is agent, 90 Chambers street, New York. They are sold from the following list, which is subject to a discount of 40 and 10 per cent.:

	Per doz.
No. 50 Steel Mortar Hods, galvanized, 24x12x13 inches	$45.00
No. 60 Steel Mortar Hods, black, 24x12x 13 inches	39.00
No. 55 Steel Brick Hods, galvanized, 21x6½x9 inches	34.50
No. 65 Steel Brick Hods, black, 21x6½x9 inches	28.50

Concentrated Soldering Flux.—Paul Thomas, Richard and Delevan streets, Brooklyn, N. Y., states that this flux manufactured by him, makes no poisonous fumes, does not discolor or stain the material, contains no free acids, does not injure tools or hands, runs free and easily, unites as strong as possible, is suitable for all purposes, and is absolutely non poisonous. He also states that, as the flux is of the highest possible concentration, it must be diluted with about two to three parts of water to one part of flux, bringing the actual cost to 1¢ ℔ lb. The flux is sold at the following net prices, f.o.b., New York:

	Cents.
In Barrels, per pound	4
Smaller quantities	5

Rosin.—As shown in our Metal and miscellaneous quotations, there has been a slight change in the price of Rosin. The change is in the nature of a reduction of from 1¢ to 15¢ ℔ barrel of 280 lb. The higher grades are the ones in which the greatest changes occur.

Pittsburgh Tin Plate Works, New Kensigton, Pa., are manufacturing a line of Roofing Plates, upon which the following prices are quoted, applying to New York and Chicago:

Kensington, IC, 14 x 20	$6.75
Kensington, IC, 20 x 28	13.50
Kensington, IX, 14 x 20	8.00
Kensington, IX, 20 x 28	16.00
Westmoreland, IC, 14 x 20	6.25
Westmoreland, IC, 20 x 28	12.50
Juno, IC, 14 x 20	5.75
Juno, IC 20, x 28	11.50

Avery Steel Tote Shop Box.—Avery Steel Mfg. Company, Chicago, for whom Wm. H. Jacobus is agent, 90 Chambers street, New York, are manufacturing this article. It is sold from the following list, which is subject to a discount of 40 and 10 per cent.:

Steel Tote Shop Box.

	Per 100.
No. 2, plain, 18 gauge, 18 inches long, 10 inches wide, 5 inches deep	$100
No. 4, plain, 18 gauge, 21 inches long, 10 inches wide, 5 inches deep	120
No. 6, plain, 16 gauge, 20 inches long, 10 inches wide, 5 inches deep	143

The above sizes are carried in stock; other sizes will be quoted on application.

Harvard Pants Stretcher.—This article is put on the market by Geo. H. Gregory, 35 Arch street, Boston. It is sold to the trade at $6 per dozen.

The W Stake Irons.—The malleable Surface and Mortise Stake Irons, manufactured by the Minnesota Hardware Company, St. Paul, Minn., are sold to the trade at the following net rates:

No. 1, Surface Iron	10 cents each
No. 2, " "	13 " "
No. 3, " "	16 " "
No. 4, " "	20 " "
No. 20, Mortise Iron	14 " "
No. 30, " "	17 " "
No. 40, " "	21 " "

Steel Web Picket Fence.—The De Kalb Fence Company, De Kalb, Ill., are manufacturing this Fencing. The list price of the Fence, 6 cables, 37 inches high, is 13 cents per lineal foot, which is subject to a discount of 30 per cent., f.o.b. De Kalb.

Wire Board and Ornamental Strip.—This article, which is manufactured by the De Kalb Fence Company, De Kalb, Ill., is sold to the trade at 3½ cents per pound, f.o.b. De Kalb.

Lake Superior Stone.—A. W. Chase, 107th street and First avenue, New York, has issued a new price-list of Lake Superior Stone, which is as follows, subject to a discount of 40 per cent.:

	Per pound.
Stone, 8 x 2 x 1½	$0.26
Slips, 3½ to 5 inches long	.40
Penknife Pieces 3½ to 5 inches long	.48
High Rounds	.40

Mounted in Polished Cases.

	Per dozen.
3½ x 1	$3.50
4 x 1½	4.00
5 x 2	5.00
6 x 2	5.50
7 x 2	6.00
8 x 2	6.50

Scythe Stones are quoted at $12 per gross, subject to a discount of 40 per cent.

Glass.—There is little of interest in the Glass market at present and no changes in prices or in the condition of trade. Local dealers report a moderate amount of trade, while factories are represented as shipping their product so that stock is not accumulated. Improved conditions in weather are likely to increase the demand for Glass in the near future. At a meeting of the National Window Glass Company, held last week, no action regarding lower discounts was taken. It is understood that the Glass importers of New York and Boston held a meeting at Boston on the 28th inst., looking toward concerted action in regard to prices. The Plate-Glass Market continues in a satisfactory condition, both in regard to prices being sustained and in the demand. We quote prices as follows: American Window Glass, 2000 boxes at one time, 80 and 10 and 10 per cent. discount; carloads, 400 boxes, 80 and 15 per cent. discount; less quantities than carloads, 80 and 10 per cent. discount. Freight allowed on car lots and over, not to exceed 17½ cents per 100 pounds; less than car lots, f.o.b. at shipping point. French Window Glass, 75 and 10 and 5 per cent. discount to 80 and 5 per cent. discount. American Plate ranges in price from 60 and 2½ per cent. discount to 60 and 5 per cent. discount. Imported Plate Glass, 60 per cent. discount to 60 and 10 and 5 per cent. discount.

Old Rubber.—The following are the current prices paid for Old Rubber delivered in New York:

Car Springs, in ton lots, ℔ lb.	....	@	$0.03½
Rubber Shoes, in ton lots ℔ lb.	....	@	.03
Large Hose, ℔ ton	....	@	9.00
Wringer Rolls, ℔ lb	....	@	.04½
Wringer Wire Rolls, ℔ lb	.01	@	.02
Syringes, ℔ lb	....	@	.05

Old Metals.—The following are the current prices paid for Old Metals in New York:

Heavy Copper	℔ lb 9½¢
Light and Tinned Copper	℔ lb 8½¢
Heavy Brass	℔ lb 7¢
Light Brass	℔ lb 6¢
Lead	℔ lb 3½¢
Tea Lead	℔ lb 3½¢
Zinc	℔ lb 2¾¢
No. 1 Pewter	℔ lb 14¢
No. 2 Pewter	℔ lb 7¢
Wrought Scrap Iron	℔ gross ton, $13.00
Heavy Cast Scrap	℔ gross ton, 9.00
Stove Plate Scrap	℔ gross ton, 6.00
Burnt Iron	℔ gross ton, 4.00

Old Rags, Paper, Etc.—The following are the current prices paid for Old Rags, Paper, &c., delivered in New York.

No. 1 White Rags	℔ lb		4 ¢
No. 2 White Rags	℔ lb		3 ¢
Mixed Rags	℔ lb	1½ @	1¾¢
Blues and 3ds	℔ lb	1¾ @	2 ¢
Hard Sized White Shavings	℔ lb	2¾ @	3 ¢
No. 1 White Book Shavings	℔ lb	2¼ @	2¾¢

The Cut-Nail Card.

TOUCHING on the advantages and disadvantages of the new Cut-Nail card, we have the following letter from a leading house in Georgia, who express. it will be observed, their desire that the Cut-Nail manufacturers should adopt a card based on the value of each size, whether or not the Wire-Nail manufact-

urers should see their way clear to taking similar action:

We are pleased with the new Steel Cut-Nail card, for the reason that it does away with averages; that it prevents small dealers, who buy on very high averages, from demoralizing the market by quoting Nails on a lower base price in consequence of their advantage in buying on high averages; that it makes the comparative cost between Wire and Cut Nails easy to arrive at, and that it necessitates salesmen remembering only one instead of two cards. While these are good, strong reasons in favor of the new Nail card, we think it was founded on a dangerous policy rather than on true business principles; that is, it was adopted through necessity rather than on the relative value of the various sizes of Nails, and for this reason we believe the card cannot be of any great duration.

We would be very much pleased to see the Cut-Nail manufacturers adopt a card based on the value of each size, even though it did not conform to the advances as made by the Wire Nail manufacturers.

Trade Notes.

Among the novelties for which the Stark Machine & Tool Company, Buffalo, N. Y., are manufacturing Dies and Presses are, Novelty Soap Powder Holder, for A. F. Stowell, Rochester, N. Y.; Automatic Garden Sprinkler, R. G. Parks, Walla Walla, Wash.; Improved Refrigerator Traps, for Baldwin Refrigerator Company, Burlington, Vt.; Ice-Cream Freezer Cups, Shepard Hardware Company, Buffalo, N. Y.; Improved Ice Cream Spoons, M. L. Sebech, Lewisburg, Pa.; Novelty Tea Pots for Aldrich & Ray, Buffalo, N. Y.; Improved Dinner Bucket for Grier Bros. Company, Dubois, Pa., and Improved Dinner Pail, Star Dinner Pail Company, Pittsburgh, Pa.

E. B. Finch, 239 Front street, New York, manufactures the New Daisy and the Popular Oil Stoves; also the Daisy Lamp Stoves. Cuts of these goods and some interesting particulars are given in an announcement elsewhere.

The J. F. Pease Furnace Company, Syracuse, N. Y., make an interesting announcement elsewhere in this issue relating to the Economy Heaters and Furnaces of their manufacture. The apparatus include combinations in a number of patterns, Steam Heaters, Hot-Water Heaters and Warm Air Furnaces in several patterns.

F. H. Lawson & Co., Cincinnati, Ohio, direct attention in an announcement elsewhere to the Lawson Old Process and Kalos Old Style Roofing Plates. The former is described as made of the finest Siemens steel, heavily coated, each sheet squared and stamped and the Kalos, which, from its name, must be a beautiful article, is described as an old style Roofing Plate, stamped and squared, with extra heavy coating.

The Otis Steel Company, Limited, of Cleveland, Ohio, are preparing an exhibit for the World's Fair, showing some very intricate shapes made out of Otis Steel by the Avery Stamping Company of Cleveland, Ohio.

John Grossus' Sons, 389 Main street, Cincinnati, Ohio, in an announcement in the advertising columns this week, direct attention to Warm-Air and Ventilating Apparatus of their manufacture. Cuts of Heaters are shown and the general advantages are stated.

In the advertisement of Gummey, Spering & Co., Philadelphia, Pa., they direct attention to Gilbertson's Old Method Roofing Plate, the special features of which are noted, and also refer to the Pennsyl Old Method Roofing Plate. They likewise state that they are manufacturers of Climax and Phenix Roofing Plates.

The Joseph Dixon Crucible Company, Jersey City, N. J., favor us with a calendar for the month of April. It is carried on a card measuring 3¼ x 5½ inches, which is embellished with a design consisting of scraggy boughs of a tree supporting what we assume to be a bird's nest made of Dixon's American Graphite Pencils. Above the design are lines by Margaret E. Sangster, as follows:

"And the prettiest thing in the world will be
The building of the nest."

Among recently authorized corporations in Illinois are the following: The Jackson Stove Mfg. Company, at Chicago; capital stock, $150,000; for the manufacture of stoves and fittings; incorporators, Thomas E. Paxton, C. E. Conway and L. L. Conway. The International Radiator Company, at Chicago; capital stock, $100,000; for the manufacture of materials for heating railroad cars with hot water and steam; incorporators, Charles Pfeifer, Joseph Shackelton and P. H. McCarthy. The Farquhar Heating Company, at Chicago; capital stock, $150,000; to conduct a general house heating and manufacturing business; incorporators, Albert F. N. Hambleton, Milton J. Farquhar and Charles Loughridge. The Chicago Electric Headlight Company, at Chicago; capital stock, $200,000; for general manufacturing and to deal in electrical goods; incorporators, John T. Van Smith, Arthur Horton and Clarendo B. Eyer. The Elevator Safety Appliance Company, at Chicago; capital stock, $20,000; for the manufacture of elevator appliances and novelties; incorporators, Richard Robins, Henry L. Norton and John J. Hayes. Chicago Steel Company, at Chicago; capital stock, $100,000; for the manufacture of iron and steel; incorporators, Roswell H. Buckingham, E. M. McKenney and A. Lehmann. Havana Metal Wheel Company, at Havana; capital stock, $15,000; for the manufacture of wheels; incorporators, Lewis E. Waterman, Harvey J. Phelps and Orland B. Thorp. The Electric Propeller Company, at Chicago; capital stock, $200,000; for the manufacture of electric propelling apparatus machinery; incorporators, William C. Marshall, David C. Kling and Louis C. Depproft.

The Chicago Stamping Company, Chicago, will remove their store rooms and offices May 1 from their present location to their new buildings adjoining their factories at Harrison, Green, Peoria, and Congress streets. The increase in their business has made it desirable to concentrate their factories and stores to facilitate the execution and shipment of orders with the least delay.

Walbridge & Co., Buffalo, N. Y., issue an artistic catalogue of Fine Builders' Hardware, which shows to advantage the line of goods displayed. The cover is finished in cream and gold with embossed work and raised letters, the plates and covers being held together with colored silken cord. The above company have recently fitted up a special room for the display of fine house trimmings, in which samples of the different finishes mounted on all the natural woods ordinarily used are shown. In this catalogue a photographic view of the interior of the room is given, and also larger views of each of the sample boards. The sample boards are made of oak, mahogany, cherry, white enamel, sycamore, maple, &c., which show to advantage the various finishes of Polished Bronze, Old Copper Bronze, Gold Enamel Bronze, Bower-Barff, Oxidized Silver, &c. The assortment shown is varied and comprehensive. The firm were led to fit up their bronze room to facilitate the selection of suitable Hardware by architects, builders and owners, as the necessity of harmony between the style of architecture of a building and the patterns and finish of the trimmings was fully recognized by them.

The Hart Mfg. Company have been incorporated at Troy, N. Y. The capital stock of the company is $50,000. The company are to manufacture cans, pumps, faucets, &c., in Troy. The directors for the first year are: William A. Thompson, James F. Cowee and Charles W. Hart.

A. B. Olsen, Kansas City, Mo., manufacturer of Olsen's Automatic Ejecting Rotary Corn Poppers, reports a heavy demand for all the different sized machines made by him. He is at present engaged on an extensive order for his Poppers, to be used in the World's Columbian Exposition in Chicago. Mr. Olsen also advises us that he is forming a stock company, with headquarters in New York City, to manufacture his Corn Poppers for the New England States, New York and Pennsylvania. This company will have a capital of $25,000, and will sell only in the localities above mentioned.

Matthai, Ingram & Co., Baltimore, Maryland, manufacturers of Tinware and kindred goods, who suffered recently from fire, announce they are not as badly damaged as they at first supposed. They have already commenced to rebuild and will push along vigorously. The damage to the retinning department proved to be not as great as at first appeared, and operations there have already been resumed. A large stock of Dripping Pans were stored in another building and, barring a few sizes, shipments are being made as promptly as usual. They will have the retinning and galvanizing departments entirely isolated hereafter from the other buildings and made as nearly fireproof as possible.

The Allerton, Clarke Company, 23 Lake street, Chicago, is a recent incorporation of which S. W. Allerton is president, C. C. Clarke is treasurer and C. A. Rosecrans is secretary. They are sole Western agents for L. A. Sayre, Norwich Lock Mfg. Company, The Arcade File Works, Columbia Tin-Plate Company, Columbia Encaustic Tile Works and Irondale Steel and Iron Company. The officers of this new company are men of high standing and long business experience, and, as the foregoing list shows, they represent a number of exceptionally high-class manufacturers of articles handled by the Hardware and allied trades.

New uses are being found for aluminum by the Illinois Pure Aluminum Company, Lemont, Ill.; an aluminum slate pencil is their latest product. The pencil is light, and, the makers claim, indestructible; the marks are erased with a wet sponge. The pencils are about the length and size of an ordinary slate pencil, and are partially covered with assorted colored paper. A crease around the blunt end of the pencil affords a place for fastening a string.

The Pecora Paint Company, 3600 North Fourth street, Philadelphia, Pa., have a very striking advertisement elsewhere in this issue respecting various Cements and other articles of their manufacture. The announcement in blue and red calls attention to the Pecora Roofing Cement, the Indestructible Stove Cement, the Pecora Asbestos Furnace Cement and the Pecora Plumbago Paint. All these goods are commented upon, and users of Cements and Paints will do well to note the advantages mentioned.

A slight change in the *personnel* of the firm of James M. Robinson & Co., manufacturers of Sheet Metal Working

Machinery, Cincinnati, Ohio, has taken place. William Moser, the "Co.," retires from the firm, having purchased the Tobacco Tag department of the business, while J. M. Robinson will conduct, as heretofore, the Sheet Metal Working Machinery department of the business, and will give to the latter more attention. He will also increase the facilities for the production of that class of machinery, including the Globe Cornice Brake.

The company recently organized at North Tonawanda, N. Y., for the manufacture of the Spang Pressure Blower and Exhausters have been incorporated as the North Tonawanda Mfg. Company. It has been announced that the company would be known as the Electric City Machine Company, but it was not possible to obtain articles of incorporation under that title. The company begin business with a large number of orders booked.

Berger Brothers, 237 Arch street, Philadelphia, Pa., have a page announcement elsewhere of the various goods that they manufacture and handle. Illustrations show eave-trough hangers, tinners' trimmings, registers, pipe straps and very many other goods, and the text gives a further notice of them.

The Thatcher Furnace Company, 3 Peck slip, New York, refer to the Thatcher Furnace as having a large and rapidly-increasing sale in all parts of the country, and they intimate that dealers will do well to secure agencies.

New Publications.

The Standard Guide to Chicago for 1893. World's Fair edition. 552 pages. Scarlet cloth. Published by the Standard Guide Company, 358 Dearborn street, Chicago.

This is a completely revised edition of Flinn's publication on Chicago, which has now become thoroughly known as one of the best of its kind. It is profusely illustrated and contains a great deal of interesting matter pertaining to the business interests of the city as well as the usual details regarding points of general interest which are handled in guide books. Those who propose to visit Chicago and the World's Fair this summer will do well to provide themselves with a copy of this work, as they may then be able to lay out their time to better advantage.

Geologic Atlas of the United States. U. S. Geological Survey, J. W. Powell, Director. Washington, D. C., 1892.

The first installment of the great geologic atlas of the United States, just issued from the engraving department of the U. S. Geological Survey at Washington, includes maps of the Chattanooga and Kingston districts of Tennessee, Hawley district of Massachusetts, and Sacramento and Lassen Peak districts of California. These five sections are treated in a manner which bears ample evidence of the thoroughness of the surveys which they record. Each separate district illustrated is accompanied by a sheet of text explanatory of the general principles of the geologic atlas. Other sheets appended to the maps are descriptive of the topography, stratography, geology, structure and mineral resources, &c., of the different districts treated, together with a special sheet outlining their geological history in a very comprehensive manner. The maps descriptive of each district are 21 x 18 inches, the scales used being 1 inch to 1 mile, 1 inch to 2 miles, or 1 inch to 4 miles. These atlas sheets are beautifully engraved, and embrace distinct maps showing the topography, areal geology, structure sections, economic geology and columnar sections of each district. In the map of structure sections the sections are introduced in profile across the topographical map at intervals, upon the exact line of country which they represent. The atlas sheets being parts of one great map, are laid out without reference to political boundaries of any sort. They are not State, county or town maps, but only parts of one map of the United States, although for convenience of reference they are given such names as will readily suggest the region shown. A glance at these initial sheets will give some idea of the vastness of the work undertaken by the Geological Survey when it is known that several thousand of such sheets will be required to complete the large topographic and geologic maps of the United States now being made by the surveyors.

Progress of the South.

The Southern section of the United States is now rejoicing in a gratifying revival of prosperity after a time of business depression which has taxed their powers of endurance to the utmost. The cotton, iron and coal markets are in a sounder condition than they have been for some time. Credits are good, and there is every prospect of large business for some time to come. But, notwithstanding the period of financial difficulty through which the Southern States have passed, their progress has all along kept pace with the general growth and prosperity of the country to a greater extent than is generally conceived. Practical evidence of the commercial and industrial advance which has taken place is given by a writer in the *Manufacturers' Record Magazine*, who says that: Ten years ago the South's agricultural, manufacturing and mining products aggregated in value about $1,200,000,000. Now they are about $2,100,000,000 and are annually increasing. The increase in population during that period was only about 18 to 20 per cent., as the South has no heavy immigration to swell its growth. So, practically, the same people who ten years ago were producing $1,200,000,000 a year are now, by reason of being more fully employed, able to turn out nearly $1,000,000,000 a year more than they were then doing. They have doubled their railway mileage and quadrupled the traffic. In addition, they have increased their coal and iron production four-fold, trebled their cotton mills, added $2,000,000,000 to the assessed value of their property, doubled their banking capital, and more than doubled their manufacturing interests. That this gratifying progress has been accomplished during a decade, several years of which have been marked by great commercial depression, which materially affected all the agricultural and manufacturing interests of the Southern States, augurs well for their prospects of advance in the future, should this ratio of progress continue.

A novel apparatus is reported to have been recently fixed in front of the show windows of a few stores in Paris, pioneering the way for the introduction of the invention. It consists of a small pipe laid along the exterior of the window, from which pipe, through numerous holes, is emitted a gentle current of warm air, slighly scented, which is very agreeable to the olfactory nerves of the window gazers, while it serves the purpose, so it is said, of keeping the window clear and bright, thus more effectively displaying the contents.

There appears to be no longer any reasonable doubt that the Canadian Pacific Railway Company intend carrying into effect without delay a scheme to secure an independent terminus at New York City, by means of connecting roads from Ogdensburg, opposite Prescott in Canada.

The Metal Worker Skylight Competition.

So far as can be judged from the number and general appearance of the plans and descriptions received in response to *The Metal Worker* Skylight Competition that closed a week ago, the results are exceedingly satisfactory. The work of preparing drawings and descriptions conforming to the requirements stated in the announcement is very considerable, but the contributions show that a large number of pattern cutters throughout the country have been enough interested in the matter to submit plans. The several contributions will be very carefully read and analyzed with a view to determine their relative merit, and as soon as practicable announcement will be made of the names of the prize winners. We hope to follow this with the publication of some of the more interesting designs. The task of making a decision is, however, one that cannot be accomplished by merely glancing over the articles, and we have arranged to reach a decision by combining the opinions of several experts, each one of whom will carefully review the plans and descriptions.

Indirect Radiators as Dirt Collectors.

If the reader has ever examined the interior of a stack of indirect radiators that has been in use for five or six years, the cold air box leading to it, and the radiator connection leading from the radiator box to the register box, he has found therein the following things, or things of a similar order: Dead bodies of spiders and other insects; cobwebs and a fuzzy substance that looks like carpet sweepings, and which upon examination with a good pocket magnifying glass proves to be chiefly carpet sweepings and fiber from door mats. In some instances, where work has been carelessly done, or where wooden air boxes have been used without tin linings, he has perhaps found a deserted mouse nest, or even a brood of young mice quietly enjoying life in the cozy quarters they have appropriated. He also found a quantity of accumulated dust whose origin, as relates to its several ingredients, is as hard to trace as that of the North American Indian. Closely examined, one may find in this dust minute bits of wood and straw; earthy materials; coal ashes; fragments and fibers of paper; tobacco (almost always present if the radiators have been used in houses where tobacco is used), which in contact with the heated surface of the radiator gradually becomes dry and pulverulent like snuff. Traces of salt, spices and similar substances used in the culinary department and of medicines employed in sick rooms may be discovered. Much lint from textures used for clothing, bedding and window drapery will be found, and numbers of other substances that no use or occupation of the building appears to account for. These accumulations are distributed throughout the passage from the exterior inlet opening to the register box; but in the radiator proper they gather to clog its air spaces, to cover over with a non-conducting medium its heating surface, and to more or less vitiate the air that enters apartments through the registers.

How the Dust Gets In.

Everywhere, and under all circumstances, the processes of decay and disintegration are going on. The moth gnaws. The very brushes and brooms used to remove dust are machines for manufacturing dust. Every step taken on a carpet or floor or a gravel walk removes therefrom a part of its substance. Road surfaces are ground into powder by passing wheels. All organic substances of a solid or semi-solid texture, if left to themselves, decompose, and the solid residue turns to inevitable dust, which is borne everywhere by passing air currents and dropped in corners or wherever obstructions exist that can arrest it. In every building there is a flow of air in and a flow of air out; and these air currents carry any floating dust that is within their influence. If strong enough, they will even pick up particles of dust from retaining surfaces and cause them to float. No substance is too dense to float in moving air if only sufficiently reduced in bulk. Gold, which is one of the heaviest substances, will float with the greatest ease when reduced to the thinness of gold leaf; and by a very moderate current of air it can be carried long distances. In buildings, during that part of the year when they are required to be heated, the flow of air is principally from the exterior to the interior, and during this period accumulations of dust generated in the house do not take place to any material extent in indirect radiators; but at this time considerable dust of the heavier kind is liable to get in the register boxes where registers are placed in floors; and it may be remarked, in passing, that, as compared with wall registers, floor registers are objectionable on this account. They are, however, so convenient in other respects, that their limited use is not likely to be dispensed with. Warming the feet on floor registers when the soles have remnants of street mud clinging to them is responsible for much of the earthy matter slowly accumulating in indirect radiators. Falling in a semi-dried state into the register boxes, this mud lies and slowly disintegrates there into fine dust. In summer, when windows and doors are opened, currents are often set up through the registers in exactly the opposite direction from that of the flow when the radiators are in operation. The dust accumulated in the register boxes is thus carried along to and into the radiators, and meeting with many angles and obstructions which arrest its further progress, some of it remains permanently there, forming, together with fibrous materials, a flock that, in proportion to its thickness and extent, is almost as thorough a non-conductor of heat as felt. This must necessarily affect adversely the efficiency of the radiators so clogged by a variable but very appreciable amount. In spite of settling chambers, screens, or other appliances for removing dust from air entering cold-air boxes, much dust enters from the exterior air and insects nearly always get in from the outside. Such a mass of mixed fibrous material is a most potent retainer of floating disease germs, and no building can be kept in a thoroughly antiseptic condition when its air for ventilation is caused to pass over and through such substances.

The Remedy.

What is needed for sanitary heating and ventilation is such a construction of indirect radiators, cold-air boxes and radiator connections as will permit thorough and convenient removal of dirt as often as may be needed; and such cleaning ought to be done at least twice a year, namely, at the beginning and close of the heating season. Carried out in some systematic and economical way, appliances for effecting the result would deserve to be called a system as much, or more, than some arrangements for heating and ventilation that have appropriated that title. It is not the purpose here to suggest peculiar modifications in radiators, cold-air boxes and registers, whereby the end sought can be attained. To think out the best way of accomplishing it will take some time and a good deal of careful attention to mechanical details. Our object has been to point out a defect and to show that it is remediable. The time is ripe for the introduction of anything that can clearly be shown to make for the highest sanitary conditions in dwellings, hospitals and schools. A large class of American people have now become possessed of wealth that enables them to have the best of everything; and in the selection of their personal surroundings they care little for cost when it fairly promises to them increased health, comfort and luxury in living. We do not know of any data in existence from which to calculate the loss of efficiency in radiators through accumulations of dirt, but the information could be obtained by a series of experiments.

The Evolution of Advertising.

A gradual change has been noticeable of late years in the methods by which men advertise their business, and—incidentally—themselves. A tendency to some artistic effect, combined with originality and greater simplicity may be observed in the various channels utilized for this purpose. The crudeness and wordiness of old-time advertising notices are giving way to a style which is very much more pleasing and concise. Pithy sentences replace the old long-winded announcements which the public has no longer the time or inclination to stop and perruse. The advertisements which are to-day the most effective are those of few and striking words, presented so that he who runs may, nay must, read. These are often embellished by decorations of a very meritorious kind, with a choice and blending of colors which show that the artistic perception has been employed in their arrangement. This kind of advertising board or notice is usually flanked by others embodying quaint conceits in phraseology or illustration which equally command attention and perusal. In a word, modern advertising to be effective must be artistic, original and concise. "no others need apply" for public favor. This change and improvement in matter and method is almost equally observable in the press "ads." of to-day. We refer here, primarily, to those in trade journals; the daily press is still hopelessly unartistic. A comparison of the advertisements placed by manufacturing and other firms 20 years ago, or even less, in the columns of trade journals, with those of the same concerns to day shows a marked improvement in style and effect. The cuts are better and clearer, the text more readable and to the point.

Catalogues and Signs.

The circulars and catalogues now issued by manufacturers are a striking proof of the general tendency to art in advertising. Many of these documents are gotten up in the highest style of artistic excellence, gilding and glorifying even the most prosaic and homely of wares by presenting them in a setting so attractive as to compel recognition. These catalogues are consequently prized and preserved where their more unassuming predecessors usually found a short road to the waste basket and an ignominious end. An advertising circular which is also an artistic production will, as a rule, command sufficient respect to be at least read, which, after all, is the end and aim of all advertisements. So art in advertising pays, as bad taste or ugliness does not pay. People will not be attracted by a commonplace or homely announcement any more than they will be attracted by a human face of such a character, no matter how meritorious the inward reality of either may be. Similarly in the cities the obvious tendency in the matter of store signs is to less ostentation and a rich simplicity. The ponderous painted signs conveying name and business at length are, in common with the great hanging signs which once so universally projected over the sidewalks, visibly yielding to a plain board, or, more often, to a brass or metal plate usually bearing no inscription beyond the name of the firm or owner. The business is allowed to advertise itself in the show windows. There is no longer thought to be any necessity to announce in large letters what one sells, when the information can be obtained by the object lessons placed for that purpose in the windows. The old time realistic signs—a boot, hat, glove, umbrella and so forth, which mutely told their owner's trade, are, like the Arab, silently stealing away, and will probably be only known by tradition iu the next generation. Now-a-days, a neat but massive plate of metal with the name engraved or imposed upon it in artistic lettering, is placed over the door, or in the form of a shield at its angle, while some of the most modern and up-to-date establishments are content with a single name carved in stone over the portal. This is supposed to give an idea of opulence and substantial elegance which could not be conveyed by the sprawling decorative signs covering square yards of the store frontage, which formerly prevailed. They are calculated to inspire confidence in the respectability of the establishment, and the change is, it must be admitted, more soothing and pleasing to the eye than the old store front covered with advertisements and bristling with sign boards.

Dear Building Material at Chicago.

All classes of building material, except iron and steel, have greatly advanced in price in the vicinity of Chicago on account of the heavy demand created by preparations for the World's Fair. Brick, lime, stone and lumber are all considerably dearer than they were a year since. The most notable rise seems to have taken place in sash and doors and inside trimmings. Discounts on manufacturers' lists which were 65 per cent. last spring are now only 40 per cent., showing an advance of over 70 per cent. on the net price then realized. The World's Fair demand has been a grand harvest for these manufacturers, whose trade had previously suffered most keenly from overproduction. It is now feared that the sudden curtailment of this demand, which will take place in May or very shortly thereafter, will have a disastrous effect. Numerous building projects, however, have been deferred for this very reason, and the building trades of the Northwest may be sufficiently well employed on miscellaneous work during the summer to counteract to a great extent the expected depression following the World's Fair rush.

Right of Seller to Hold or Reclaim Goods Sold.

A universal principle of law of the greatest importance to the seller of goods is that which gives him a lien on goods sold for the payment of the price thereof, commonly called a vendor's lien. Not only is this recognized at common law, but in most of the States, if not in all, there have been enacted specific laws providing that the seller of goods shall hold a lien for the price over them. But, of course, before this right will arise, the property in the goods must have passed to the purchaser, for a person cannot have a lien on goods belonging to himself. Neither will this lien extend to anything beyond the price of the goods. It will not cover a claim in the seller for storage of the goods, even if it is by the purchaser's default that the goods are kept in warehouse, or other charges are incurred in detaining them. The seller of goods has this lien upon them for their price, unless it is otherwise stipulated, so long as they remain in his possesssion, and, as against purchasers who become insolvent, until something occurs to make it inequitable for him to maintain it. A seller cannot follow property beyond the purchaser from him, as against the claim of any one, save one who purchases from such purchaser with notice. So if a creditor in good faith takes a mortgage, without notice of the unpaid purchase price of the mortgaged goods, he has a lien superior to a subsequent attachment for the purchase price. One who loans another money with which to purchase property, or pays for the property of another, has no vendor's lien or privilege thereon. A very interesting case arose in Massachusetts, where the owner of a large quantity of wood, which was lying in a pile on his own land, having sold a portion of the same, and measured off and marked the part sold, with all agreement that the purchaser might remove it within a year, gave the purchaser a bill of sale of the wood, and received from him his promissory note for the price, payable in six months, before the expiration of which time the purchaser became insolvent. On the one hand, it was contended that the title to the wood had so passed that when the purchaser made an assignment it vested in his assignee. While, on the other hand, it was insisted that notwithstanding the peculiar nature of the transaction, as the wood remained as it originally lay on the seller's premises, it was in his actual possession, and on the purchaser becoming insolvent, the seller had a right to detain it until payment or tender of payment; and this the Supreme Judicial Court agreed in. A vendor's lien may, of course, be waived by express contract, and any agreement which is inconsistent with its retention operates as a waiver of it. His lien is also waived by implication, as when the vendor receives some other security for the payment of the price. But a written receipt for cash and notes of the purchaser "in full payment" for property, the title to which has been retained by the seller until payment of the purchase money, does not operate to discharge the seller's lien as against the purchaser's assignee for creditors in the absence of evidence that the transaction was intended as a discharge. And where a note is taken as collateral for the price of goods they are, as between the parties, subject to a lien therefor. However, where one takes, as part of the purchase price, the note of another than the purchaser, it constitutes payment and is a discharge of the purchase money lien. And where one has assigned a note taken as part of the price, and is held only as an indorser on it and has not paid it, he is not in a position to claim a purchase money lien. The lien is also lost where goods have been sold in block for a lumping price, and proof sustains it on a part and fails to sustain it on the rest of the goods, on account of the impossibility to separate the price. It is also lost when goods have been unpacked and mixed with others, so that they can no longer be identified. The object of this lien being simply to secure payment of the price of goods; if the purchaser tenders that it will release them. Actual transfer of possession will also usually destroy the lien, as indicating an abandonment of it: but not always, as courts of equity will aid the seller in cases of insolvency and the like, where innocent third persons are not thereby injured, and in many of the States statutes to this effect have been passed. Where delivery would destroy the lien, merely marking the goods in the purchaser's name, or setting them aside, or boxing them up by the purchaser's orders, and putting his name on them, will not do it, so long as the seller holds them and has not agreed to give credit on them. Furthermore, the retention of open control by a seller's employee over machinery placed in the works of a company, which are being fitted up by the seller, is notice to said company of the existence of a vendor's lien.

THE TIN SHOP.

Patterns for Elbows in Elliptical Pipe.

From E. D., *Milwaukee, Wis.*—I would like to have meth ds published in *The Metal Worker* for describing the patterns of two-piece elbows in elliptical pipe. Patterns to be for elbows having their flat and narrow sides to the front.

Answer—The patterns for elbows in elliptical pipe are obtained in the same general manner as for those in round pipe. The profile is to be turned broad or narrow side to view, as may be required. In Fig. 1 the profile is turned with the narrow side to the view. Then, in Fig. 1, let A B C D represent the profile of pipe from which the elbow is to be made, E F G H J K the elevation of elbow, and F J the joint or miter line. The profile A B C D is drawn in line with one arm of the elbow, as shown. Divide the profile into any convenient number of equal parts, as shown by the small figures. With the blade of the T square placed parallel with K J of elevation, bring it against points in the profile and carry lines cutting the miter line F J. On E K extended, as L M, lay off a stretchout of the profile, through the points in which draw the usual measuring lines. With the blade of the T square placed parallel with the stretchout line L M, and brought successively against the points in F J, cut the corresponding measuring lines, as shown. Lines traced through the points thus obtained, as indicated by L P O N M, will give the desired pattern.

In Fig. 2 the same profile is used as in the previous instance, but is turned with the broad side to the view. In this fig ure A B C D represents the profile, Q R S T U V the elevation, and R U the miter line. To obtain the pattern, divide the profile into any convenient number of equal parts, and with the blade of the T-square placed parallel with V U of elevation bring it against the points in the profile and drop lines, cutting the miter line R U. At right angles to V U lay out a stretchout line of the profile, through the points in which draw the usual measuring lines, as shown. With the blade of the T square placed parallel with the stretchout line L M, and brought successively against the points in the miter line R U, cut corresponding measuring lines, as shown. Trace a line through the points thus obtained, as shown by P O N. Then L P O N M is the pattern desired.

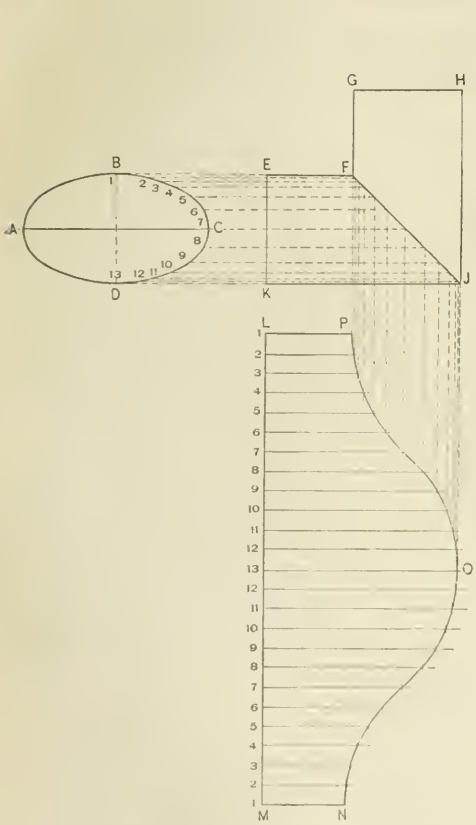

Fig. 1.—Profile Turned with Narrow Side to View.

PATTERNS FOR ELBOWS IN ELLIPTICAL PIPE.

THE LETTER BOX.

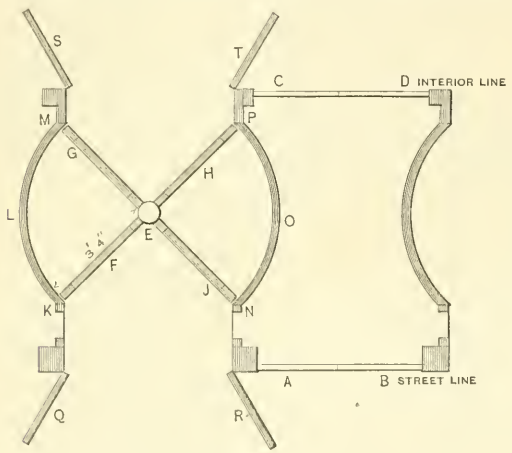
Soldering Flux.

From M. T., *Riverside, Cal.*—Could you inform me through *The Metal Worker* where I can obtain a soldering flux which is put up in the form resembling small cakes of beeswax?

Note—A soldering flux of the description our correspondent inquires for can be bought from The Norton Bros.' Can Manufacturing Company of Chicago, Ill.

Turnstile Storm Doors.

From E. R., *Chicago.*—The tallest of the tall buildings of Chicago is the Masonic Temple, 22 stories high, which is located at the corner of State and Randolph streets. The main entrance to this building was provided with two lines of swinging doors to prevent the air from entering in tremendous volume and rushing up the great elevator shafts. There are five sets of such doors, to accommodate the vast multitude of people who pass in and out of this huge building daily. These doors were at first arranged as shown in the accompanying plan, A B representing the outer doors and C D the inner. It was found that, as people were continually passing in and out during business hours, the doors were kept "on the swing," and consequently open most of the time, thus affording an opportunity for the air to enter after the manner of a cyclone. To remedy this condition of affairs, turnstiles were placed in alternate doorways, filling the entire space from top to bottom. In the engraving, E represents a wooden post which turns on iron pivots, the lower pivot entering the floor and the upper pivot the ceiling over double door way. F, G, H, and J are four glazed wooden doors secured to the post, thus forming the turnstile. These doors have rubber faces. The wood work on either side is represented by K L M and N O P. Glazed sash are placed at K and N. The doors Q, R, S, T can be secured in the position shown while the turnstile is in use. As the affair is arranged, people can enter the building through the turnstile by passing to the right and leave in the same manner, yet at no time is there presented a free passage for cold air to enter the building. During cold weather the doors similar to A, B, C and D are fastened, but can be used when the weather permits, thus allowing people to enter by these doors in place of the turnstile, if desired.



Turnstile Storm Doors —Entrance to Masonic Temple, Chicago.

Equalizing the Temperature of Rooms.

From A. P. W., *Somerville, Mass.*—In *The Metal Worker* of March 18, replying to "R. N. W." on the subject of withdrawing cold air from rooms to an extent that will render it possible to have the air at floor and ceiling at the same temperature, you offer suggestions toward the accomplishment of that end which do not seem to me as being competent, if fully carried out, to achieve that object. You state that the desired result—that is, the removal of cold air—can be attained by properly ventilating the rooms by registers, either near the floor level or located in the floor itself. I fail to see how this can be effected by having the register and the heated flue or duct so located. In the first place, it is difficult to perceive how the cold air is to be drawn out, even with the assistance of the hot air duct, from the opening at the floor, where the coldest stratum of air in the room is to be found. Suppose, for argument's sake, that the flue leading from that register or opening heats the column of air contained in the smoke pipe of the heater, and that such air ascends. Does any one imagine that the cold air from the floor will rush after it through the opening to be heated and ascend in the same manner? I do not think so. The motive force which causes the upward motion of the heated air is gravity, which acts by means of the greater weight of the cold air outside as compared to that which becomes heated in the duct. We know that air, being rarefied by the heat, becomes lighter than that which surrounds it, and that it ascends until it reaches that region of the atmosphere where the same degree of rarefaction exists. The air outside the duct, under a normal pressure of 15 pounds to the square inch, waits but the chance to obtain an entrance at the base of the column, and the velocity with which this is accomplished depends on the difference in weight between the ascending column of heated air and the descending column of cold air. If the cold air to be withdrawn through the floor opening be of the same temperature, or nearly so of the incoming air, there will be little or no displacement of the air in the room, whatever amount of circulation may be going on in the duct. The removal, therefore, of the cold air from the room through the heating of the air in the duct does not seem a thing that can be satisfactorily accomplished.

The establishment of a uniform degree of heat in all parts of the room presents a like difficulty. Air expands about $\frac{1}{490}$ of its volume for every degree of heat imparted to it, according to the best authorities. If, therefore, there is any artificial heat applied, be it ever so little, expansion will ensue and the ascent of the air so rarefied to the ceiling will at once commence, the colder air falling to the floor, to be made subject to the same law of expansion, by means of which a difference will always exist between the temperature at both extremes, viz., floor and ceiling, proportioned to the amount of heat applied, on which account your correspondent will find it difficult to extract the cold air from the room by what is known as "aspiration," or "the application of heat to move vertical columns of air in chimneys or heated up-cast shafts." Edward S. Philbrick, C. E., a well-known authority on the subject, in his *American Sanitary Engineering* says: "The extraction of the foul air near the floor can only be effected by special apparatus contrived for the purpose, with some aspiratory or mechanical force to move it," also that "the introduction of the fresh air near the floor is the simpler method." Again he says: "If the foul air be taken from the top of the room its higher temperature as compared with the outside air will provide for its (upward) motion." Summarizing my conclusion, therefore, I maintain: 1. That the cold air cannot be "drawn" out of a room by means of a heated duct opening in or near the floor, because of no expansion taking place at that point sufficient to act as a motive power of ascension. 2. That if any artificial heat is allowed to operate on the air in a room an equal temperature cannot be maintained at the floor and ceiling and intermediate space. 3. That if the cold air is to be removed it must be by mechanical means and not by gravitation. I may add also that it is conceded that no rooms can be "properly ventilated" merely by "outlets." There must also be "inlets" to do the work effectively, for the very essense of "proper ventilation" is changing the atmosphere—that is, displacing or expelling the vitiated portion, by the introduction of fresh or purer air.

As regards the ventilation of halls, churches, &c., the futility of attempting this plan will be better understood by reference again to Philbrick, who says that a hall heated in the first instance to 60° must be so ventilated as afterward to supply fresh air at the rate of 30 to 40 cubic feet per minute for every person in

the hall, and carry off the same amount of vitiated air without unnecessary drafts.

Note.—The argument that a room cannot be ventilated by heated flues drawing from the floor will hardly be borne out by experience. It seems to us that our correspondent has gone astray in his criticisms by assuming that the cold air in a room is the same temperature as the air out of doors. If this were so there would undoubtedly be a very sluggish current up the ventilating flues, for the air would only rise as it became heated to a higher temperature than the outside atmosphere. As a matter of fact, however, in speaking of the cold air of a room, the word "cold" is used in a relative sense only. It is cold as compared with the air in the upper part of the room, but on the other hand it is warm compared with the outside air, and this being so, it will be drawn up a heated ventilating flue.

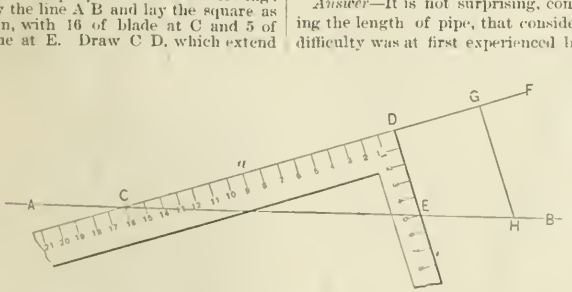
Air Chamber for Suction Pump.

From G. W. B., *Bradford, N. H.*—Is there any fixed rule to determine the size of an air chamber for a common suction pump.

Note.—There seems to be no uniform rule by which pump manufacturers proportion the size of air chamber to that of the cylinder of common suction and force pumps. Take any half a dozen common pumps of different makes and manufacture, but all having the same bore or cylinder capacity, and it will be found that the air chamber or barrel varies all the way from three quarters to twice the size of the cylinder. On information obtained from hydraulic experts, we believe that it is well to proportion the air chamber of a pump so that it will be of ample size, say about one and a half times the capacity or size of the cylinder.

Circumference From Diameter.

From J. D. A., *Remington, Ind.*—In *The Metal Worker* of January 21 I notice a communication from "C. E. L.," New Haven, Conn., asking for a short rule for finding the circumference of a circle when diameter is given. In answer to the above inquiry I submit the following: Draw the line A B and lay the square as shown, with 16 of blade at C and 5 of tongue at E. Draw C D, which extend

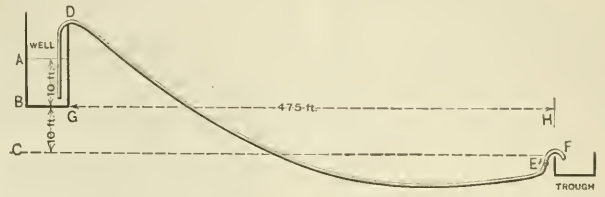


Circumference from Diameter.—Method Suggested by "J. D. A."

indefinitely, as shown by C F. To obtain the circumference of a circle, from C on C F space off three times the diameter, and at the point thus obtained erect a perpendicular to C F, cutting A B. The distance from this point where the perpendicular cuts A B to C will be the circumference. In the diagram the diameter C *a* was spaced off three times from C to G, and G H drawn; accordingly C H is the circumference of a circle having the diameter C *a*. The above method is convenient to use for finding the circumference of small circles, and I find nothing to equal it for tinners' use.

Difficulty with a Syphon.

From A. A. R., *Clifton Springs, N. Y.*—I had a job done last summer which is not satisfactory, and perhaps the editor of *The Metal Worker* can explain where the difficulty lies, if a proper description is given. I attempted to convey water through a 1-inch galvanized iron pipe from a well (fed by a spring) to a trough, the distance being 475 feet. The bottom of well is 10 feet above top of trough, and there is usually 10 feet of water in the well. Water did not run through the pipe for two weeks after the job was completed. One day, while pumping at the lower end of the pipe, there was a loud report like the "thumping" in steam pipes, and water poured through the pump rapidly, and continued to do so for several weeks. After that water would run freely through the pipe at times, at other times just a little, or not at all. Many people have looked the job over and failed to discover the difficulty. Some are of the opinion that it will never operate properly with iron pipe, but will if lead pipe is used. All the joints were well leaded and screwed together tight, so no air can enter the pipe, which is free from traps or short bends. It was expected the pipe would operate as a syphon, so there would be a continual flow of water from the lower end. Referring to the inclosed sketch, A B represents the water in the well, which is 10 feet deep. From bottom of well to top of trough, B C, is also 10 feet. From well to trough, G H, is 475 feet. A globe valve was placed at E for regulating the flow of water through pipe providing it would operate as a syphon. A full stream of water can be procured by means of the pump, which is placed at F.



Difficulty with a Syphon.

Answer—It is not surprising, considering the length of pipe, that considerable difficulty was at first experienced by our correspondent in exhausting the air contained in the pipe so water could be drawn by means of the pump placed at F. Regarding the action of the syphon, the weight of the atmosphere upon the surface of water at the sea level is about 14.75 pounds per square inch. If the syphon X D F, when arranged as shown, is filled with water, the end X being below the surface at A, the weight of water in D F will be greater than in D X. As the water runs out of D F, the pressure of the atmosphere upon the water at A will force the water up the pipe X D.

The pump being operated at F, exhausts the air contained in the pipe, and the pressure of the atmosphere upon the surface of the water at A forces the water up X D, thus filling the pipe. The pipe once filled with water, it can be drawn by means of the pump, or the pipe will operate as a syphon. Providing there is no air at D, there appears to be no reason why the flow of water through the pipe cannot be regulated by the globe valve at E. On the other hand, as air contained in the water collects at D, the flow of water will be retarded or interrupted, depending upon the amount of air at this point. As the pipe is arranged at present, it is intimated by our correspondent that air contained in the pipe can be exhausted by means of the pump at F, after which the pipe operates as a syphon, and this action continues until air again collects at D. It thus appears that, in order to have the pipe operate as a syphon, some means must be provided for exhausting the air that collects at D. If the present arrangement is not satisfactory, and if convenient to do so, the experiment could be tried of running the pipe in a direct line from D to F, and locating the pump at D and placing a stop cock between the pump and pipe. The end of pipe at F being under water, by opening the stop cock below pump, and operating the pump, the air contained in the pipe would soon be exhausted. The stop cock could then be closed to prevent any air from entering the pipe through the pump valves. This operation could be repeated as often as air collected in the pipe. Regarding the kind of pipe to be used, the water might encounter some resistance in coming in contact with the ends of the iron pipe at the joints, but providing there were no leaks or short bends, it is probable there would not be enough difference between iron and lead pipe to decide the operating of the job.

Now that the word "failure" has been finally written over one of the most gigantic frauds of the age—the Panama Canal—added interest is felt in the alternative interoceanic waterway of Nicaragua. The completion of the Maritime Canal of Nicaragua, to connect the waters of the Atlantic and Pacific oceans, is loudly called for in many quarters. This canal, which has been commenced by an American company, will take a course some hundreds of miles further north than its ill-fated rival, and therefore will be considerably more convenient for United States vessels.

WORLD'S FAIR NOTES.

Railroads Giving Bad Service.

With the opening day of the Fair less than a month distant every effort is being made by the officials to complete the work of preparation. The most serious delay now is caused by the unreasonable time taken by the railroads in delivering freight. The material for a large number of exhibits is kept by the railroads from ten days to two weeks when the distance hauled is only a few hundred miles. Even after the cars reach Chicago it generally takes four or five days to get them switched around. The Belt line, apparently, makes no effort to expedite the World's Fair cars. They lie on the side tracks for days, while exhibitors fume and fret at the chiefs of departments and the secretary of installation. Frequently exhibitors have brought a force of workmen from their home shops and the delay incurs a heavy loss to them, besides putting off the work that long. An aggravated instance of this kind last week came up in the installation office. The missing cars were traced finally to a side-track at Grand Crossing, less than two miles away, where they had lain a week without an effort having been made to get them to Jackson Park.

The material for the aquarium of the Pennsylvania Fish Commission has been over two weeks on the road. The officials are in Chicago waiting for the cars to arrive, but nothing can be heard from them. Cars over the Milwaukee & St. Paul have been two full weeks in reaching the park over the Belt line.

Although 200 cars a day are now being delivered at the fair the Transportation Department has had no trouble in handling the stuff as fast as it arrives, and the work is kept close up. The entire blame for the delays rests on the railroads, which handle exhibits the same as they would haul coal, and without the slightest apparent effort to get out of the rut. If the cars get side-tracked there they remain until the exhibitors fill the offices with complaints.

Exposition Roofs All Repaired.

Rain now has no terrors for the World's Fair chiefs or the exhibitors, for the roofs are at last water-tight. The great task, which was ordered by Chief of Construction Burnham before leaving for New York a week ago, was practically completed last Wednesday. A regiment of workmen had been employed. On the day previous there were 800 in the roof force, and 400 of them freckled the vast expanse of the Manufactures Building. There are still some repairs to be made, but they are more to preserve the roofs than to stop leaks.

The cost of repairing the roofs is estimated at about $100,000. This figure is given by a contractor's superintendent, who has much to do with the repairs. A portion of this sum was due to the snow slides on the Manufactures Building and Machinery Hall, but by far the larger part is chargeable to poor material and poor workmanship. The material for some of the roofs did not cost over 50 per cent. of what it ought. The contractors, however, were not altogether at fault. Canvas roofing was something new to most of them, and, as the roofs were only to last until the close of the fair, they naturally selected light material. The winter was against them, and a heavy loss has resulted. A considerable portion of the roofing was done with corrugated iron or steel, and even this was not as well laid as it should have been, but had to be repaired.

All the repair work has been charged against the contractors, but where they have been paid in full the exposition may have difficulty in collecting from their bondsmen. The contracts provided only that the roofs be water-tight, and did not specify the material. Some of the contractors say they will not stand the cost of repairs made by the direct order of the exposition and will fight the case in the courts.

Instead of waiting for rain the repaired roofs have been tested by water from a hose, and have not been left until they were shown to be water tight by resisting a downpour of rain.

Michigan's Exhibits.

In more ways than one the State of Michigan proposes to make itself known at the fair. Besides a building costing $50,000 it will have the only logging camp on the grounds, an exceptionally fine mineral exhibit, a grand horticultural show, and other conspicuous objects of interest. The State has been going along without saying much, but constantly making preparations for patronizing and supporting the exposition on a large scale. The Michigan board is the only State organization that has as yet opened an office on the grounds.

"In the Mineral Department, Mines Building," said Secretary Smith, "is where we expect to scoop the world. I have no hesitancy in predicting that when the doors are opened Michigan's exhibit there will attract as much attention and admiration as any other State or any other country on the globe."

The exhibit will be displayed in a pavilion made of stone, iron, ore, copper, crystallized salt, silver, gold, granite, marble, verde antique and other specimens of minerals taken from the quarries and mines of Michigan.

One of the unique attractions inside this pavilion will be a biblical representation of Lot's wife turned to a pillar of salt. There will also be a specimen of copper ore as it comes out of the mine, 98 per cent. pure and weighing 10,000 pounds. The cost of this pavilion is estimated at $20,000. It will stand in the center of the building opposite Germany and England, and is being constructed under the supervision of Peter White, member of the board for Marquette, and Jay A. Hubbell of Houghton.

The State has an outdoor space just south of Machinery Hall, where is being constructed a genuine logging camp 70 feet long and 20 feet wide. It will be an exact reproduction of the camps Michigan lumbermen live in, and the daily bill of fare, corn bread, pork and beans, strong black coffee, &c., will be the same as they have in the woods. Besides the camp there will be in this show the largest load of logs ever put on a sleigh and drawn by a single span of horses. These logs were cut and sent by Nester Bros. of Baraga, on the Sturgeon River. The load consisted of 50 pine logs, each 18 feet in length, piled in ten layers, varying in the number of logs from eight in the second layer to one capping the load. The biggest log contained 1225 feet, board measure, and the smallest 404 feet, and the whole weighed 300,000 pounds, or 150 tons. The logs were just cut, and were consequently heavy with sap and frost. They were loaded by means of chains and a pair of horses, with the assistance of three men. It took 1 ton of chain to bind the load together. The top of the last log was 33½ feet above the bottom of the runners of the sleigh. The horses weighed but 1700 pounds each and they pulled the load 80 rods on a level road to the rollway. The sleigh and team will be taken to the fair and the logs loaded again just as they were. It took ten standard size flat cars to transport the load to Chicago. The sleighs had 9 foot runners and 14-foot "bunks." That is, the width of the load was 14 feet. Near the camp will be a log train of five cars, and all about the place specimens of the tools used by lumbermen from the opening of the first camp in Michigan down to the present time.

Besides these State exhibits Michigan will be represented by about 1000 of its citizens with individual exhibits of manufactured goods and novelties, the products of their toil and genius.

From the Bay State.

Six carloads of the Massachusetts State exhibit are now in Chicago. There is included in this shipment the entire mineral section of that State's exhibit and much of the old fashioned furniture with which the Massachusetts headquarters will be furnished.

Commissioner Hovey, who is at the head of the Bay State Commission, says Massachusetts' exhibit in the agricultural department will be especially fine and will embrace many interesting features. Most prominent in this section will be the displays from the State agricultural training schools and experimental farms. Especially noticeable will be the educational section of the Massachusetts exhibit. Harvard University will make a magnificent display in this connection. The Massachusetts headquarters are now nearly completed. The building is a reproduction of the historic Hancock mansion and is among the finest of the State buildings.

Germany is Easily in the Lead.

Chicago papers say that it is at last possible to foretell where the honors of the exposition will go among the nations of the earth. Germany will be entitled to the first place among foreign exhibitors. The young Emperor's enthusiasm, spreading to his subjects, has produced the most magnificent exhibition of resources any nation has made outside of its own boundary lines. The beautiful structure, bearing the words "German Empire," has never been excelled as a national offering in a foreign land. It has been only since that structure neared completion that its beauty and imperial magnificence have come to be appreciated on the grounds. No one doubts that it is in Jackson Park to stay, for once the people of Chicago have seen it and roamed through its halls, public sentiment will not permit its destruction.

Mythology and metallurgy are a queer combination, but the pavilion now rapidly approaching completion in the Mines Building, which is to contain the exhibit of the great German iron works operated by the Barons Strumm, embraces in its details both of those sciences.

German mythology is illustrated by the devices with which the pavilion is decorated, and metallurgy is illustrated in every feature of the exhibit. The Strumm Brothers operate a plant that requires the employment of 5000 men. They are among the most advanced of the world's great iron manufacturers, and their display fully typifies the wonders that may be worked out of that base metal.

This structure will be 46 feet high and will occupy a floor space of 37 x 108 feet. The rear walls are of masonry, but the front elevation will be composed of heavy iron and steel manufactures of every conceivable device. Various German legends are being worked out in the design, merchant shapes forming the decorative material. A great portal in the center will give access to the pavilion. Over the entrance will be this inscription: "Vereinigte Eisenwerke Gebrueder Strumm, Nuenkirchen und Rudolph Boecking, Hallberger Huette." This will be worked out in mosaics with cinder and slag. Over this device will be the word "Strumm," also fashioned in the same manner. Iron and steel beams of different shapes will form the side columns of the portal, and surmounting the lettering will stand, upon a scroll of intricate design, a life-sized mythological figure of hammered copper

The scroll is made of manufactured iron pipes such as are turned out by the carload every day at the Strumm works.

At each of the four corners of the exhibit will be placed a large obelisk formed of T rails, round, angle and flat bars and various other products of the Strumm Mills grouped in artistic designs. These pyramids are 50 feet high. The two nearest the entrance are composed of transverse sections of beam iron. The trophies in the rear are of the same hight as those of the front elevation. The one on the right is composed of pipe iron, while that on the left is formed of band and strap iron, having the form of a gigantic flower stock, and fastened together at the base by hoops and coils of wire of various circumferences.

The rear of the pavilion is formed of solid masonry, and the front will be inclosed with a post and chain railing. The posts are samples of the results that may be obtained in iron and steel decorations. The head of each post consists of some familiar mythological god or goddess wrought in iron and steel, while the foundations are composed of manufactured articles of the same material.

The rear wall will be covered with photographs of the mammoth works of the Strumms, and there will be displayed the history of the concern since it was founded. The art of iron working has been brought to its highest development by this firm and their entire display is calculated to illustrate the schievements accomplished in that branch of industry in the past decade.

One of the most interesting parts of the exhibit is the immense iron rail which will form a portion of the frieze in the rear of the pavilion. This rail is 200 feet long and is bent in the form of a scroll, having been bent cold.

All along the front of the exhibit excellent paintings in oil are hung representing the various buildings and departments of the works. The visitor will also find there statistical references, such as the number of workmen employed in each division, the annual production, and the benevolent institutions for disabled and sick employees and their families, &c. Solid obelisks, 30 feet high, connected by scrolls of solid steel and cast iron, surround the interior of the mammoth exhibit.

Herr Maver, who superintends the construction of the pavilion, is a young man who has secured a position of responsibility in the great establishment. He is a graduate of the Saarbruecken Gymnasium. He served a year in the Garde-Fuesilier Regiment. He also completed a course in the Royal Technical School of Saarbruecken.

From New South Wales.

One of the most interesting displays that will be seen within the great structure devoted to mines and mining will be that now being prepared by the representatives of New South Wales. The work of installation is being superintended by J. E. Carne, F. G. S., of the Department of Mines, of Sydney. Speaking of the display yesterday, Mr. Carne said:

"It will undoubtedly surprise the American public to learn that in point of value gold does not rank first among the minerals of New South Wales. Coal will be made a feature of this exhibit, and it deserves the honor, because it is our most valuable mineral. The order of the output of the minerals of the colony is coal, gold, tin and copper.

"As a whole this exhibit may be said to be a heroic display of base metals. Along the front line will be massive trophies of silver ore, tin, copper and antimony. One particularly interesting feature will be the silver monument, which is to be erected at the northeast corner of the exibit space. It will represent one sixth of the entire output of the great Broken Hill Mine, which from May, 1886, to May, 1892, produced 36,500,000 ounces of silver and 156,000 tons of lead.

"In the rear there will be a triple arch, with two center pillars of coal and two outer pillars of petroleum oil coal, which is locally known as kerosene shale. These pillars will be 4 feet square and 11 feet high. Behind this feature will be shown full sections of principal coal scenes.

"That portion of the display which will be first seen by the visitors will be made up of bulk trophies of gold, siver, copper, tin, antimony, iron, manganese and chrome and building stone. These will be made as attractive as possible. Then there will be show cases containing collections of all metallic and non metallic minerals. In these collections will be some of the most valuable specimens ever discovered Quartz and placer gold and gems will be displayed as a distinct feature. And then there will be collections of fossils from the principal sedimentary formation. These will be accompanied by geological maps that will give one a comprehensive understanding of the physical formation of the colony."

The Great Waterbury Clock.

A few days ago the story was cabled to America that England would set up within the Manufactures Building a clock that would tell the time o' day in more ways than any other clock ever constructed But when the makers come to install that feature they will find, anomalous as it may seem, that they are way behind the times. In the center of the big building will be displayed a mammoth clock that will chime the time for all, built by the Waterbury Clock Company, that in the diversity of its accomplishments will be to the English clock as an hour is to a minute.

It was the original intention of the Waterbury Company to complete its clock so that it might be placed on exhibition at the Paris Exposition in 1889, but the scope of the undertaking assumed greater proportions as the work progressed, and it has been completed only a few weeks.

The timepiece stands 16 feet in hight, with a 6 foot base. It is made of black walnut, highly polished and handsomely carved with scenes representing American history from the landing of Columbus to the present time. At the lower part of the clock and on each side is an allegorical scene representing mechanical progress during the last century, every figure in each group being in motion.

The largest scene is in the center of the clock. It represents the "train room" of the Waterbury Clock Company, with all the shafting and machinery in operation and 25 operatives at work. The figures go through every motion of work in that department.

Four scenes are represented on the sides of the clock. The subjects are, first, a cotton gin in full operation in a cotton field, with the negroes carrying the cotton in from the fields and placing it on the cotton gin, while Eli Whitney, who stands by, is explaining the working of the machinery to a planter. A second scene shows the old method of manufacturing cloth. The operatives are at work beating the flax and preparing it for the looms and spinning wheels. A third scene represents a coal mine with the cage working and the miners digging into the banks of coal.

In a fourth scene is a representation of the improvement in sewing machines. Elias Howe is watching the work of one of his machines, while close by modern machines are plying, and in another adjacent group are a number of women laboriously sewing by hand. The fifth group indicates the advance in the electrical world. Electrician Daft is represented operating a dynamo. The sixth shows the interior of a telephone and telegraph office with operators at work and messenger boys running in and out.

Scene seven contrasts the old and new methods of manufacturing watches, showing the improved factories of the present day and a kitchen in Switzerland where watches were made by hand a century ago. The last is an old-fashioned saw mill with the saw running, logs moving, and children playing near by.

The figures are all operated by an electric motor and are constantly in motion. The center of the clock is occupied by a beautiful water color of the buildings of the clock company, while just above is the handrome dial of the clock. It is 3 feet in diameter and indicates the days of the week, month, and year, the hours, minutes, and seconds of the day, and the moon's phases and tides. Each figure represented is an exact likeness, and the whole is complete in every respect. At the top of the clock is a handsome carving of the "Declaration of Independence" with a reproduction of the famous old Liberty bell.

Will Light Chicago Harbor.

During the exposition season seven miles of the Lake Michigan front will be lighted by means of electric buoys. This is to be a feature of the fair, and will form a part of the Government exhibit.

Capt. W. S. Schley, U. S. N., who is now in charge of the Third Light House District, the headquarters of which is at Tompkinsville, Staten Island, arrived in Chicago last week. He will have charge of the work of arranging the line of buoys, and will superintend the greatest electrical experiment ever undertaken in any country.

If Captain Schley is successful harbor navigation will be revolutionized. The current for the lights will be furnished from one station. A power station will be erected at one end of the line and one cable laid the entire distance they propose to light. The wire will be of very small caliber at the dynamo, and taper up to about an inch at the return end. It will be made in this manner to save any loss of the current by friction. It is proposed to send 1500 volts over the entire line from one station, and a sufficient current will be taken off by means of a converter to supply each individual light. Fourteen miles of cable have been received, and will be used to complete the return circuit. The cost of the experiment will be about $25,000. To light the harbor by the old system would cost ten times that amount.

A Pavilion of Solid Mahogany.

One of the most magnificent and unique pavilions being constructed within the Manufactures Building is that which will house the exhibit of the Meriden Britannia Company. This pavilion is little more than 20 feet square, and yet will cost about $40,000. It is being constructed of solid mahogany and plate glass. It fronts on Columbian avenue, opposite the pavilon being erected by Germany. If the exhibit is worthy of the pavilion it will certainly be the finest of its line in the department.

A new method of securing cheap electric light from refuse has been exploited in England. A company has been formed in London, under the name of the Refuse Disposal Company, with the object of handling the dust refuse of cities and utilizing it, through the medium of destructors of their own design for electric lighting purposes. It is claimed that 20,000 tons of house dust, treated according to their system, may be made to produce as much as 5,600,000 indicated horse-power.

Hot-Air Heating.—II.*

(Concluded.)

LOCATING STACKS AND REGISTERS.

To insure the very best results from any job of heating, the location of furnace, stacks and registers should be planned out before the work of construction begins; and, while the owner cannot be expected to carry out the wishes of the furnace dealer to his own inconvenience, it will be found in planning a job that minor changes in the setting of partitions and swinging of doors and placing of studs and joists can be made without trouble, that will insure much better results from the heating than if the heating is ignored until after the studding is up. The general rules for locating stacks and registers are simple and easily borne in mind. The stacks should be placed as near to the furnace as possible and in a position to make the branches to the registers as short as possible, for the air in branches must travel in a horizontal direction, retarding the flow of air and losing in heat and volume. In many houses, as at present built, there is a main girder running lengthwise through the building on which the floor joists rest, and the stacks come down on this girder. The stack proper comes down to a point just below the floor line, and to complete the stack a boot is used with a collar to connect to the hot-air pipe. This boot is of different shapes and styles, as the position of each stack may be slightly different. When a stack comes down on the top of a girder and the joists are placed on top of the girder, an offset boot, as shown in Fig. 6, can be used.

Occasionally the joists are mortised into such a girder and the bottom of the stack comes down almost immediately on top of it, in which case the girder must be sawed off at an angle in order to allow the boot to be placed and a connection made with the stack.

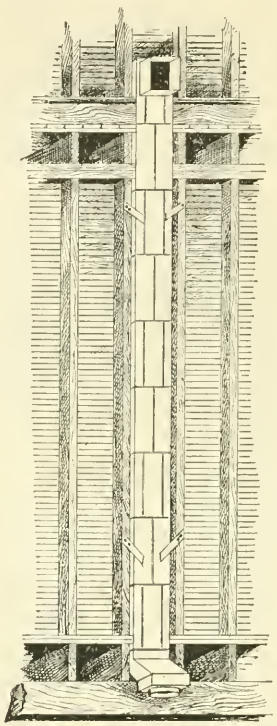
The cutting off of the girder, as indicated, weakens it to some extent, but is the best thing to be done under the circumstances. When a girder does not run through the house the stack generally comes down between the joists or along side of them, in either of which cases the attaching of the boot is a simple matter and the proper boot is easily selected. For stacks coming down between joists and near the center of space between, the boot shown in Fig. 7 can be used.

At times channels are cut in chimneys or walls to allow the stack to go up, in which case the stack is extended below the joist line and the boot attached as shown in Fig. 8.

A custom has prevailed in some parts of the country of running stacks down below the joist line, putting bottoms on them and cutting in collars on the sides of the stacks. This is a practice to be condemned in the strongest terms, for the reason that the sharp turn where the hot-air pipe joins the stack retards the flow of air and largely reduces the effectiveness of the stack and causes undue radiation in the basement. This class of work is done under the mistaken idea that it is more economical; but it is a mistake, for the boot costs actually no more than does the extra pipe needed to run down the stack below the joist line. In putting in the stacks they should be placed in the interior partitions, if such a thing is possible, and there are few cases, where space cannot be found for such stacks in the interior partitions. On all strictly first-class work it is supposed that double stacks are used. The outside size of the double stack is made 3⅝ inches in depth, so as to go within the 4-inch studs

* Reprinted from copyrighted catalogue of the Excelsior Steel Furnace Company, Chicago.

Formerly these stacks were made 3¾ inches in depth, but owing to the fact that the mill men have been dressing their studs down to less than 3⅝, it has been found necessary to change the size of the stacks. The inside stack is smaller to allow the circulation of air around it, and these stacks as made will be found to be absolutely safe and with their use no fire can result. The stacks are made in all sizes, so that the furnace dealer will select for each room a size of stack large enough to heat it. He will then place it in the partition that is the most accessible, having the carpenter on the job do the cutting necessary to get it in. If the job is planned carefully there will be no cutting of any importance, for in putting up his interior work the carpenter will have before him the plan showing the location of each stack and register, and will have the holes cut and the places for the registers framed out in case framing is necessary. If the register is at a distance from the stack a branch must be used to connect the stack with the register. This branch may be double square pipe, the same as the stack, or round pipe, double, of the same capacity as the stack. If a square pipe branch is used the connection will be made by means of a square stack collar, which is cut through the outside pipe and into the inside pipe and held in place by the notched edges of the collar, which are turned in and bent down to make a permanent connection. On the other end of the branch, which is of suitable length, the register box is placed and the ends of the branch are notched with the snips, the hole in side or end of box cut out and the branch connected in the manner described in case of the square stack collar. A better branch, and one more easily put in, is the branch consisting of two sizes of round pipe, one without the other and which is connected in the manner described, a round stack collar being used.



Hot-Air Heating.—Fig. 6.—Showing Manner of Using an Offset Boot in Connection with a Stack Over a Girder.

In some cases furnacemen prefer to make the connection with the register box by means of a collar, and in this case the collar is made a little larger in diameter than the regular collar, for in a connection of this kind the round or square pipe branch slips over the stack collar on the stack and inside of the collar attached to the box. As a rule, the former method is followed, although the connection is possibly not quite so neat or mechanical.

The registers should be placed as near to the stack as is possible, as explained in the above; also they should not be placed near the windows, nor where the doors will swing over them. It is a current idea of many people that a register should be placed under a window, but a little thought will convince any one that this is wrong, for air being a vapor and expanding as it is heated must force its way up into a room filled with colder air, and if the register is placed near a window, where the air is the coldest, the cold stratum of air will resist the entry of the warm air, and the heated air will have great difficulty in forcing its way into the apartment. If a register is placed where a door will swing over it the door will be warped. Furthermore, it is not advisable to place the register in the wall, for the reason that the circulation is not so good from a wall register, and the wall will be somewhat discolored by the dust that is occasionally blown up through the pipes, and which can be swept up from the floor without material damage.

With the double stacks excellent results will be obtained, but in a very particular job, where the maximum of heat is to be obtained with the minimum of radiation, these stacks can be wrapped with one or two thicknesses of asbestos paper and the little radiation in the partitions that results from the use of double stacks prevented in part.

The asbestos paper is not needed in general work, as the loss by radiation with double stacks is extremely small.

We are aware that in many parts of the country single stacks are wholly used and that exception will be taken to our allusion to the use of single stacks, but facts are facts, and we deprecate the use of single stacks no matter how well wrapped with asbestos paper. Asbestos paper is an article that is supposed to be absolutely fire proof, and genuine asbestos paper will not burn; but a certain class of papers have been sold for asbestos papers which contain a fibre that will burn, and if asbestos paper is used for wrapping stacks it should be the genuine article. We also find in many cases the asbestos paper is only wrapped around the stack and not pasted. In some cases it is only tied on with a cord or wire, which soon slips out of place. Even when it is put on properly there is more or less radiation and loss of heat, and in many cases the asbestos paper has been gnawed off by rats and mice and the single pipe entirely exposed. The only advantage in using a single stack is to get an increased space in the stack, which certainly is an advantage, but the disadvantage more than offsets it. It is a simple matter to move a stud an inch or two and thus get the extra space, or if it needs to be, furrow out that part of the wall where the stack is to go and get space sufficient for a deeper stack.

There are times and places were wall registers have to be used, and in such cases it is advisable to use convex registers, as they deliver more air than do the ordinary pattern registers. When wall registers are used the register should be placed as near the floor as possible.

We notice in plans sent to us that some dealers and house owners make provision for conducting the heat to the upper floors

by using one or more flues in a chimney. This is to be deprecated, for the loss of heat by radiation in the flue is very great and economical results cannot be obtained.

We have said above that stacks should be run in the interior partitions, but there are extreme cases where no suitable opening can be found on the inside, and the stacks must go in the exterior walls, and in such cases double stacks must be used, and in addition wrapped with three or four thicknesses of asbestos paper well pasted, and even then the stack should be of extra size if reasonably good results are to be obtained.

the outside branch pipe. In running branches where the distance is greater than one joint the branch should be supported either by wire attached to nails driven into the joists or else by short pieces of wood nailed between the joists.

The first floor outside box has an outside collar to give the job a finish. Some dealers omit the collar, leaving simply the hole for the inside box collar to slip through, but this leaves a raw edge on the outside box which does not look well. Single round pipe branches are in general use and are all right when wrapped with asbestos paper. Some of our cuts showing stacks and branches extween the furnace and joists by wire attached to nails or screw hooks. If the bonnet on the furnace is concave, the concavity can be filled with sand and the radiation much reduced.

What has been said above refers chiefly to residence work, and contemplates first-class work such as should always be done. Some little money can be saved by following other methods and being less particular; but the extra cost of good work over poor is so little that it does not pay either the dealer or house owner to have poor work done. Poor work has not infrequently killed a good furnace in a town and retarded the progress of im-

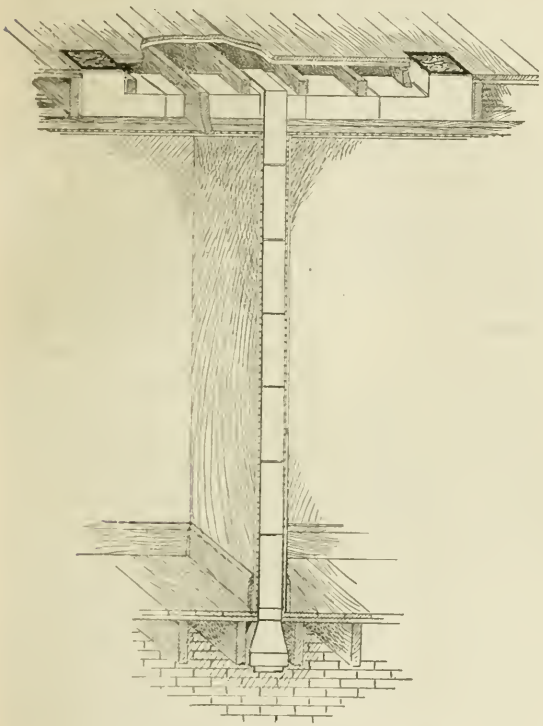


Fig. 7.—Style of Boot to be Used When Stack Runs Between Joists.

HOT-AIR HEATING.

REGISTER BOXES.

In putting in register boxes a common custom is to put in single boxes, and, to prevent liability to fire, to line the surrounding joists with tin. This is all well and good, but there is no economy in so doing, as there is a better and no more expensive way, and one which produces a more finished job. We refer to the use of double register boxes, or the placing of one box within the other. When the work is started and the holes are being cut for the stack the locations for the registers can be determined and the holes cut for the outside boxes, whose flanges are turned over and nailed to the rough flooring. They can then be protected by boards nailed over them and left till the job is ready for a finish, when the boards are removed, the inside boxes put in and the job completed.

On the second floor the inside box is connected with the inside branch pipe and the outside box is connected with

hibit single pipe branches. Before leaving a job it is important to test the furnace flue, for if the draft is defective the heating of the furnace will be greatly diminished. A cold flue will not draw well at first, but if of proper size will work well after it is warmed up. The proper size for hard coal is 8 x 12 on the inside and plastered smooth. In many houses you will find flues of smaller size, and when they are straight good work is obtained from them, but often a flue smaller than 8 x 12 gives serious trouble. For soft coal the flue should be one-half larger.

By wrapping the smoke pipe with asbestos paper the radiation of heat is reduced. The smoke pipe should be of galvanized iron. Black iron will answer, but has to be frequently renewed. If the top of the furnace comes within a foot of the joists a roof should be placed over it. This may be of galvanized or black iron, with a thickness or two of asbestos paper pasted on both sides and suspended be-

proved heating of all kinds, simply because of the ignorance or willfulness of the parties who placed the original heaters, and which failed to realize the anticipations of the purchasers.

There are, of course, many variations from the line of procedure set down in the foregoing and which will produce equally good results, but the work if put in as set forth can hardly fail to produce satisfactory results with any standard furnace of the right capacity.

MEASURING FOR CONNECTIONS.

We have given one method of running connections from a furnace, presupposing that the furnace was set in the basement and material for the connections on the ground. Another and possibly better way, but which involves some extra work to the novice, is to go to the building before the furnace is set, locate the furnace, take the center of that location and draw a diagram of the basement, then taking the center of location of furnace and two

walls of basement at right angles with each other, the exact distance of each box or boot from the walls can be noted on the diagram, which should be drawn to a scale. This diagram can be taken to the shop, and the exact number of feet of pipe, number of angles and elbows, dampers, and other materials needed calculated, and in addition the bonnet can be taken and the casing collars cut in before being sent out from the shop.

HEATING STORES, CHURCHES, ETC.

In heating buildings of the class referred to judgment comes into play so largely that it is not possible, without having each particular case before us, to do more than give some general rules.

In heating a store the most satisfactory plan is to have the furnace placed in the basement at a point some few feet from the center in the direction of the front entrance. Then above the furnace place a large register equal in capacity to the furnace, and connect the furnace with a register equal in size for supplying the cold air and located near the main entrance. The philosophy of this method is that in a store the front door is opened frequently and the register at that point will get the cold air when the door is opened and also the colder air of the store when the door is closed and thus supply the furnace. An outside duct can also be used in connection with the inside duct.

This system can be modified in case of there being two entrances at different sides of the building and two cold-air registers used, one at each entrance. Also two or more hot-air registers can be used, the only difficulty being that in heating a large store large pipes must be used and if registers are placed some distance apart the pipes must have sufficient elevation or a loss of heat by radiation will result.

In heating churches and schoolhouses this same system in modification can be used, locating in halls and vestibules the cold-air return registers, and in both cases the interior air can be used before the assembling of the congregation or scholars and when the rooms are filled the outside cold air supply can be used altogether if desired.

On large and complicated work it is desirable to give each job particular study if the best results are to be obtained. In public work there is more risk than on private, for there are more people to satisfy and more difficulties to be overcome. In large work ventilation becomes almost an essential, and some system should be incorporated. We ask attention to the section following this, in which we describe a simple and effective system of ventilation.

VENTILATION.

Every one knows that air once breathed becomes vitiated, owing to the carbonic acid gas with which it is charged, and is therefore unfit for breathing, and the primary object of ventilation is to get rid of this impure air and introduce a supply of fresh air. A secondary object is to facilitate the heating of the apartment. It is obvious that no two bodies can occupy the same space at the same time, and as warm air from a furnace must be forced into the rooms above, the air in these rooms must find an exit somewhere. Exits are often found in the spaces around the doors and windows, but are rarely sufficient to carry away the impure air as fast as formed. Carbonic acid gas as thrown out by the system is a mild poison, and being heavier than air falls to the floor, where it is liable to be breathed by children. The gases liberated by coal also collect on the floor, and hence a system for conducting away this foul air is almost a necessity. A system of sanitary ventilation should be introduced into every home during the process of construction, and the additional expense of such a system is small in comparison with the advantages gained in heating and the benefits derived from the standpoint of health and comfort.

The system that we advocate is simple and very successful. It is not a theory and not an experiment, and can be carried out at a small cost while a building is under construction.

In the modern house several flues are usually built into one chimney for convenience and economy, and one of these flues should be used exclusively for a ventilating shaft and connected with each apartment by means of pipes running between the joists, floor or side wall registers being placed at some point opposite the hot air registers, to which the ventilating pipes run. In order to be effective, however, it is necessary that the ventilating flue should be alongside of a flue that is used by the furnace or kitchen range, in order that this ventilating flue be warmed and a suction or current created. A ventilating flue will fail to do its work if not located where it will be warmed, as the foul air cannot force its way up a shaft without assistance. This shaft should be of ample dimensions, so that no matter how crowded an apartment is at any time the foul air can be removed as quickly as formed. The furnace, if a good one, will supply an abundance of fresh and pure air at all times, and the capacity of the ventilating pipes can be reduced at pleasure by means of the registers.

Copper Plating Sheet Zinc.

According to the *Metallarbeiter* the copper plating of sheet zinc for building purposes has recently been tried with considerable success, and the process can be especially recommended where mechanical wear takes place. The zinc combines very well with copper. The electrolytic method of copper plating is advantageously used, but the zinc may be coated with copper by ordinary means. In the first place the sheet zinc is cleaned with soda from any adhering dirt and grease, and is also purified by a weak acid bath from the covering of zinc oxide. There are then dissolved in 24 parts of water 1 part of refined verdigris and 12 parts of cream of tartar; the mixture is heated to boiling point, after which 3 or 4 parts of Spanish white are added. The Spanish white is here decomposed and is precipitated as lime tartrate. The dark blue liquid is poured off and filtered, and can be used either as a bath for the sheet zinc or for the production of a copper plating paste. The first mode of application is better, as the fluid forces its way into the corners and angles of the zinc articles and is uniformly distributed all over. If it be desired to coat an immovable zinc object with copper, the article, after being cleaned, is painted with the copper solution and a chalk compound, and, after drying, it is brushed. This very simple operation would also prove of value for architectural purposes, namely, where it is desired to remedy the generally unpleasing effect of zinc ornamentations.

The manufacturers of very thin sheet iron and steel may, says the London *Ironmonger*, be glad to learn that in Germany one of the latest fads of fashion is to have visiting cards made of iron. These are said to be so thin that a pile of forty of them only reaches a thickness of one tenth of an inch. The names are engraved in letters of silver or gold upon a black surface. A correspondent thinks these cards must look like coffin furniture, but as I have not yet seen any of them I am unable to form any opinion on the subject. At the same time, one must welcome any new method of using up the enormous quantity of iron and steel which is now being produced in Europe and America.

Ancient and Modern Automata.

A little book, by Conrad Cooke, has just been published in London, England, which treats of "Automata, New and Old." In reviewing it, *Engineering* remarks: After reading it, we are divided between admiration of the skill of the ancient mechanics, and wonder at the mendacity of the historians who followed them. Marvelous as were the apparatus of which we have authentic information, they were but poor affairs compared with others whose performances have been handed down by rumor. Mr. Cook commenced by noting the automata attributed to Vulcan, but he did not get to firm ground until the time of Hero, who was not only a most able mechanic, but also managed to get his inventions well reviewed in the technical press of the day Hence it comes that we not only know what effects he produced, but how he arrived at them. He was the inventor of the piping bullfinch, of the first penny-in-the-slot machine, and of many other pieces of mechanism which have since been brought out as complete novelties. After the time of Hero there was an interval of nearly 1000 years, during which no record of automata is to be found. This carries the chronicle down to the time of Charlemagne, to whom a most elaborate water-clock was presented by the Khalif Haroun al Raschid. Speaking heads came into vogue about this time, and an automaton of clay, over which Albertus Magnus spent 30 years, is said not only to have spoken, but to have walked, answered questions and solved problems. This was destroyed by St. Thomas Aquinas as the work of the devil. The great period for the construction of automata began at the close of the fourteenth century. The list of the principal examples is too long to follow, and many of the accounts are evidently gross exaggerations. Among the more interesting are a number of clocks, such as those at Strasburg and Lyons. It was in the middle of the seventeenth century that magnetism began to be utilized in automata to form an invisible connection between the works and the moving figures. After this date we come to a period from which more reliable accounts have descended to us. Among the well authenticated automata are the musicians and the duck of Vaucanson, the writing man of Von Knaus and the figures of Le Drorz. The chess player of Baron Wolfgang von Kempelen would need to be included, had it not contained a man to direct its movements. Mr. Cook tells the real story of the fraud. There were several exhibitions of automata in London at the end of the last century, and they must have found fashionable audiences, seeing that the entrance fee, to one at least, was half a guinea. Robert Houdin was the next great constructor of automata, and after him there was none others until Mr. Maskelyn, who is still puzzling the world with his wonderful productions. For other examples of this kind of mechanism we have to look to the toy shops and to the street hawkers who sell "walking postmen" and the like.

As a result of observations taken in the center of Manchester, England, and about 1½ miles distant, it was demonstrated that the presence of smoke prevents radiation to such an extent as to make an appreciable difference in the temperature. At the town station on Saturday and Sunday evenings, when the amount of smoke produced is less, the temperature is perceptibly lower than during the rest of the week.

STEAM AND HOT WATER.

Heating and Ventilating School Houses by the Blower System—I.

By Walter B. Snow.

IMPORTANCE OF VENTILATION.

The importance of perfect school house ventilation, as regards the health of the growing child, cannot be overestimated. And yet how far, how very far indeed, from perfect is the ventilation of the majority of the school buildings of the country. Few well-to-do parents would be willing that there should be indiscriminately brought into their homes as companions for their children the very companions that their children must associate with in school; companions, perhaps, from the very "slums," uncleanly, unhealthy, diseased. And yet these children must sit side by side, must handle the same books, must breathe the same air, for perhaps five hours per day.

If we could but see filth in the atmosphere as we can view it on the stagnant pool, but few weeks would elapse in any ill-ventilated school house before a remedy was applied and the children supplied with clean, pure, healthful air.

But there is an "if" in the way; we can only rely on other senses than that of sight, and while we inhale the air, with its disagreeable "schoolroom odor," and perhaps feel dull and fatigued after breathing it for a few hours, yet as it does not really make us sick we pass it by as something inevitable. But do we comprehend that, like the constant dropping wearing away the stone, so this continued effort to sustain a healthy young life on a polluted atmosphere must eventually result to a greater or less degree in the impairment of the health of even the most robust.

Upon air in sufficient quantity one's life is dependent; upon the purity of that air does the health depend. If we would bring up a generation of children not crammed with book knowledge, although they may have attended school, but educated, alert and healthy because their lessons have been learned and their school life passed in an atmosphere approaching in purity that out of doors as nearly as science can provide public spirit must be awakened.

QUANTITY OF AIR REQUIRED FOR VENTILATION.

No definite idea of the actual requirements of schoolhouse ventilation can be formed without at least a rudimentary investigation of the amount of air actually inhaled and the amount contaminated by an average person. Although the adult naturally requires more air for respiration than is necessary for a child, yet the greater emanation of odor and the greater prevalence of sickness among the young fully offsets it, and it is well in estimating to allow as much for child as for adult.

The average adult when at rest makes about 16 respirations per minute, which, at the average of 30 cubic inches each, makes a total of 480 cubic inches passing through the lungs per minute. Of this amount about one-fifth will be oxygen and four-fifths nitrogen, in addition to which there will usually be present about $1\frac{7}{16}$ per cent. of aqueous vapor and $\frac{4}{100}$ of 1 per cent. of carbonic acid gas. All this before it enters the lungs. After passing them, however, it will be found to have lost about one-fifth of its oxygen by the formation of carbonic acid, which will in turn have increased to about 4 per cent. of the total volume, an increase of 100 per cent. The water vapor will have increased to 5 per cent. and the air will have a temperature of about 90°.

In addition to the carbonic acid thus formed about ½ more is given off by the skin. Assuming that an amount of air is supplied sufficient to dilute this to the same proportion as the breath, there obviously will be required, about 580 cubic inches or 0.33 cubic feet of fresh air, to supply the fixed requirements of the body. But, furthermore, $1\frac{1}{2}$ to $2\frac{1}{2}$ pounds of vapor are evaporated daily from the surface of the skin by a person in still life. If the air is supplied at 70° with a humidity of 70 per cent. and is assumed to be saturated when it leaves the body, then at least 4 cubic feet of air per minute will be required to carry away this vapor.

Taking into consideration these various factors it becomes evident that about $4\frac{1}{2}$ cubic feet of air will be required per minute to thoroughly remove from an individual all vitiated air and to furnish fresh air for respiration and the absorption of moisture from the skin. This, however, is only on the assumption that any given quantity of air, having fulfilled its office, is immediately removed without contaminating the surrounding atmosphere.

But the spent air is immediately diffused into the atmosphere. Outdoor air usually contains about 4 parts of carbonic acid in 10,000; that discharged from the lungs has, however, 400 parts in 10,000, and therefore to secure the commonly accepted standard of good ventilation, as 6 or 7 parts in 10.000, it would be necessary to dilute each 0.33 cubic foot with 19 to 22 cubic feet of outdoor air. Hence the individual would require 1140 to 1320 cubic feet of air per hour.

But even this must be admitted to be the theoretical quantity. Of all the air admitted to the room a certain amount is sure to escape without serious contamination—that is, without doing its part as a diluting medium. For practical satisfactory results it is necessary to supply per hour per person about 2000 to 3000 cubic feet of outdoor air with 4 parts of carbonic acid per 10,000 in order to maintain an atmosphere around the individual containing not over 6 or 7 parts in 10,000.

In an ordinary schoolroom containing teacher and 55 scholars a supply per head of 3000 cubic feet per hour is equivalent to supplying to the entire room 2800 cubic feet per minute, which, with an air space in room of 250 cubic feet per occupant, would be sufficient to change the entire air of the room every five minutes

COST OF VENTILATION.

As all of the air thus supplied must be properly warmed, and as the room must be maintained at 68° to 70°, it is evident that an enormous amount of heat in the form of warm air must be discharged every moment through the vent flue to the outer atmosphere.

This heat means coal; the coal bill is visible; the effect of the best ventilation upon the health of the scholars is by no means as readily seen, for its work is long extended; consequently it will be found almost without exception that the measure of the ventilation is to be found in the size of the coal bill the school board is willing to approve. Ventilation is expensive; were it not such articles as this need never be written. The public must be educated to the fact that ventilation is a necessity; then, and then only, can we hope for marked improvement. Too often a system of direct radiation with no air supply or a furnace system with a supply that is inadequate is compared on a basis of running expense with a hot-blast system supplying from 30 to 50 cubic feet per occupant per minute, with the most natural result that the latter is deemed far more expensive. But compared upon equal volume of air supplied the tables are completely turned.

THE HOT BLAST SYSTEM.

The hot-blast or blower system, consisting of blower, motor and heater, with a system of distributing ducts and a primary supply of steam, stands to day as the only system adequate to cope with all the requirements of school house heating and ventilation. While the furnace system may be perfectly satisfactory, under certain atmospheric conditions, there are days when a dependence upon natural methods of ventilation results in a totally inadequate air supply, but with the blower system the air being impelled by mechanical means is positive in its action, and may always be driven to its proper destination.

To quote the words of experience of Robert Briggs—an expert on the subject—in a paper pertaining to mechanical ventilation: "It will not be attempted at this time to argue fully the advantages of the method of supplying air for ventilation by impulse through mechanical means—the superiority of forced ventilation, as it is called. This mooted question will be found to have been discussed, argued and combated on all sides in numerous publications, but the conclusion of all is that if air is wanted in any particular place at any particular time it must be put there, not allowed to go. Other methods will give results at certain times and seasons or under certain conditions. One method will work perfectly with certain differences of internal and external temperatures, while another method succeeds only when other differences exist. One method reaches to relative success whenever a wind can render a cowl efficient. Another method remains perfect as a system if no malicious person opens a door or window. No other method than that of impelling air by direct means with a fan is equally independent of accidental natural conditions, equally efficient for a desired result or equally controllable to suit the demands of those who are ventilated."

(To be concluded.)

The Capitol Heater Company of Detroit having acquired, as previously announced, the Bolton heater, and contemplating putting forth a line of steam

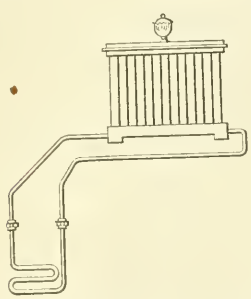
boilers, under the name Hecla, will change their name April 1, taking the more comprehensive title of United States Heater Company. The management of the company will remain unchanged, Messrs. Henderson and Smith who started the company a year ago, retaining the sole management. They have taken new offices in the Bagley Building, Congress and Randolph streets, Detroit, to provide the necessary accommodations for their largely increased business. The branch offices of the company will remain the same, that at Chicago under the management of John W. Mills, Ogden Building, and that at Boston under Gilchrist & Taylor, 106 High street.

English Practice in Hot-Water Heating—XXIII.*

EXAMPLE BUILDING WORKS.

In the following few examples it has to be mentioned, as was done when giving examples of horticultural works, that it may never fall to the reader's lot to erect an apparatus like any one of them; but by describing and also illustrating one or two methods of carrying out the works, great assistance can be rendered to the unskilled. The principles are thus made more clear, and once the principles are grasped nothing else can be gained except by actual experience. The examples are merely supposed requirements and the possibly best way of meeting them. It is impossible to do more than this as there are but very rarely two works anyway resembling one another.

Fig. 95 shows a convenient little arrangement (it can hardly be called an



English Practice in Hot-Water Heating.—Fig. 95.—Arrangement for Warming a Room Located Near that Containing the Fire.

apparatus) to give warmth into a room adjoining or near the place where the fire is. The coil is supposed to be at the back of an ordinary open grate fire, and furnishes heat to a few feet of pipe or a small radiator, which, however, should not be far away. This drawing shows a coil of three ¾ inch pipes, the top pipe being continued upward as the flow and the lower one forming the return. Two unions are shown just above the fire box to facilitate the removal of the coil if eventually it becomes fractured. There is no doubt it will fail one day if it has much usage, as dirt will find its way into the pipes and eventually fill up the lower one and cause it to split. If steam quality tube is used it will last very well for several years, only having use in the winter. A piece of copper tube for the coil would do well.

It is hard to suggest what actual work this little appliance is capable of doing—it depends upon several things. Firstly, the size of the fire. If it is a fire box holding a good thickness of fuel—that is, a mass of fuel deep from front to back, very effective results are obtained. If the fire box has wholly fire brick at back and sides (as with all good modern grates) it helps matters, and the attention to the fire will affect the heating of the pipes. In putting pipes containing water in the fire of an open grate we introduce a cooling influence that may completely spoil the utility of the grate, for it must be particularly noted that combustion effected in an open fire is very different to that in a close stove or boiler, with the important assistance

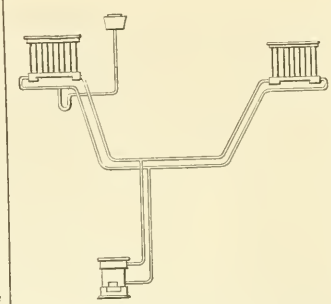


Fig. 96.—Two Radiators Connected with a Small Independent Boiler.

it has from the draft that is induced. With a close stove the draft passing through the fuel (and not over it as it does with a grate fire) causes combustion to proceed briskly irrespective of cooling influences, and this speed of combustion can be regulated just as may be required by the damper.

If the grate fire box is not a large one three pipes will have a deadening effect upon the fire, and one or two pipes only must be used for small requirements. The uses of this arrangement are that a radiator can be put into a neighboring room, which is perhaps of such a size as not to be heated by its own fire place; or it may be used to introduce a little warmth into a room that is not used regulary. If the coil was in a large fire it might be made to heat sufficient radiating pipe for the warmth a billiard room should always have when out of use.

The water supply may be provided for by a little cistern in any convenient place where it is not seen, or the radiator may be fitted with a little vase filling cup at top, as shown. This latter article then acts as an air vent. In any case an air-cock will be needed at the highest point in the radiator to allow for the escape of air as it is being filled. No stop-cock would be required with this apparatus; but a draw-off service (for emptying purposes only) might be found useful, if it can be conveniently placed.

The next example, Fig. 96, illustrates two radiators in connection with a small independent boiler, for heating an entrance hall or other similar purpose. Of course, coils or hot-water pipes could be used in place of the radiators, if so desired. There is scarcely a better purpose to which heating works can be put than this. The great gain that is effected by providing warmth in an entrance hall cannot be overestimated. This part of the house, with the staircases leading from it, has been likened to an artery, as it furnishes a constant current of air to the rooms and places that lead off from it. It must be known by every one that in nearly all cases the greater part of the air entering a house (and the volume is great) enters by the doors and openings it can find on the ground floor. This inflow is necessary, as the chimneys in a house require air, also the occupants, of course, and the house itself can well be likened to a great chimney, for an upward current of air, as a rule, always manifests itself inside. These conditions, perhaps, do not exist, or, at any rate, to such an extent when a good system of ventilation is provided; but this, unfortunately, is absent in too many cases.

Assuming that a considerable volume of air finds its way into the house by the best route it can, the larger proportion will pass through the entrance hall, and, as a rule, this part of the house is very cold. All doors in the vicinity have disagreeable drafts to them, and the staircases are in quite as bad a state. By introducing heat in the entrance hall a really important benefit is obtained. The heating medium should be placed as near the outer doors as possible, so as to contribute its warmth to the incoming air. By this means the hall is made agreeable, if not quite warm. The air entering the rooms is tempered, and that which passes up the staircases goes to make the upper parts of the house less cold. By keeping the boiler fire alight through the night the very disagreeable degree of cold experienced in the halls and staircases at early morning is prevented. Engineers are particularly cautioned against using the same quantity of radiating surface in an entrance hall as they would in a room, if they want to make a success of the job. These places are not usually expected to be of as high a temperature as a room, but notwithstanding this they require 50 per cent. more pipe. The necessity for this is due to the air of the hall being in tolerably rapid motion always, being taken by the rooms, and particularly the staircases, leading from it. If the gain effected was generally known no residence of any pretension would be without heat in the entrance hall.

In this example a small, independent boiler is shown, which would be situated in a cellar or basement room below. From the boiler is carried an inch flow and return service, by the best route (observing the principles already dwelt upon), and the pipes can be carried first to one radiator and then on to the other, or can be taken to a central point and branched each way, as shown. If the pipes be carried first to one radiator and then on to the other, the connection to the first would have to be as Fig. 94, or the second coil would be much longer than the first in heating.

In branching the services as illustrated a little better rise should be given to the pipes which extend furthest, so as to equalize results each way. There would be no need for stop-cocks in a little apparatus like this. The cold supply would be provided by a small cistern, as shown, either filled by hand or with a ball valve. If the latter, the cistern should only fill just an inch or two, so as to allow for the expansion of water when heating. An air cock would have to be fitted in each radiator and cleaning plugs and an emptying cock should be provided to the boiler.

The pipes from the boiler should be 1 inch, as just mentioned, but there would hardly be need for the branch to each radiator to be more than ¾ inch. It will be seen that the cold supply-pipe has the customary dip in it to prevent the heated water circulating into the cold-water tank. The way in which this acts has been fully explained and does not need repeating here.

HEATING NOTES.

THE HARRISBURG BOILER & MFG. COMPANY, Harrisburg, Pa., issue a catalogue attractively gotten up of boilers they manufacture. The publication, of oblong shape, is printed on heavy paper and begins with a description of the Star water-tube boiler, as adapted to power purposes. These are made in various sizes from 12 to 100 horse-power, and a table gives all the

dimensions and surfaces. Next is described the return tubular boilers, then locomotive and vertical boilers. Then comes the division relating to heating boilers. Accounts are given of the Star gas-burner boiler, Star water-tube boiler and the Star water-tube hot-water heater, besides the Star gas-burner hot-water heater. Numerous illustrations and complete descriptive text are presented. Miscellaneous goods such as flanging machines and pumps are noted at the close.

SEALED PROPOSALS will be received at the office of the Supervising Architect, Washington, D. C., until the 12th of April, for furnishing and erecting complete steam disinfecting plants at the United States Quarantine Station, Camp Low, Sandy Hook, N. J., in accordance with drawings and specifications, copies of which can be had at the office of the Supervising Architect, or at the office of the Superintendent of Public Buildings, New York City.

THE *German Valley Quarterly* comes out in its last number resplendent in blue ink and other attractive features. This quarterly, which is published by the F. D. Stephens Company, contains a lot of local news, some interesting short articles, suggestions about heating and various prominent announcements of the F. D. Stephens Company, German Valley, N. J., who, among other things, handle the Florida steam and hot water heaters.

SEALED PROPOSALS will be received at the office of the Supervising Architect, Washington, D. C., until April 26, for all the labor and materials and fixing in place complete of low pressure, return circulation steam heating and ventilating apparatus and power boiler, &c., in the U. S court house and post office building, Springfield, Mo.

THE SWAMSCOT MACHINE COMPANY, South Newmarket, N. H., with salesroom at 98 Milk street, Boston, Mass, issue a neat catalogue illustrating and describing their hot-water heater. The Swamscot heater consists of a series of horizontal cast iron sections connected together with a central water column. To speak more accurately the sections are dished so as to give an upward inclination toward the center column. They are connected together and with the fire pot by wrought iron nipples, the fire pot being surrounded by a circular water chamber. The apparatus is fully described and general and sectional views show very clearly all the features of its construction. The Swamscot heater is made in five sizes, with inside diameter of fire pot from 17 to 31 inches.

JAMES H. HUTCHINSON, New York City, has patented an improvement in radiators, the object of which is to secure large radiating surface, greater strength, free circulation and simplicity in construction. The invention consists in the combination of a radiator of inlet and outlet ports and a compound stop and check valve, consisting of a valve casing divided by a diaphragm into two chambers or passages, a stop valve in one chamber and a check valve in the other.

Gas jets, asserts an English gas trade paper, may be made important auxillaries to ventilation. Inserted in the bottom of air shafts, they establish active currents, which withdraw the vitiated air from living rooms. It has been proved by actual experiment that 1 cubic foot of illuminating gas can be so utilized as to cause the discharge of 1000 cubic feet of air; and as a common gas burner will consume from 3 feet to 6 feet of gas an hour, it will extract 1000 times that amount of air from a room each hour, if suitable contrivances are used, besides giving light.

Prize Competitions

$25.00.

Prize Competition No. 19.

SUBJECT:

Electrical Goods as a Part of a Hardware Stock.

The increasing demand for Electrical goods and their more general adoption in homes, hotels, stores, offices, public buildings, factories, and for street railroads, makes the subject a pertinent one to the Hardware merchant, especially as Gun and Locksmiths are endeavoring to absorb this line of trade in many places. The competition is designed to draw out expressions as to the advisability of including Electrical goods in Hardware stocks; to what extent these goods should be carried; assortment of goods which can be handled profitably; the best manner of arranging and displaying these goods; whether installing and Electrical repair work should be included, and to what extent electrical devices can be supplied to manufacturers and to street railroads.

This competition will remain open until April 29, 1893.

Those intending to compete are reminded that it will not be necessary to write long essays, but that comparatively brief and business-like answers will be favorably regarded as meeting the purpose for which these competitions are announced.

The following prizes will be awarded:

First prize	$12.50
Second prize	7.50
Third prize	5.00

The prizes will be awarded for answers which in the judgment of the committee of award are most suitable for publication and of the most general interest. We reserve the privilege of extending the time on any competition in case the contributions received are not of sufficient number or merit for the committee to award prizes. These competitions are open to every one, and it is hoped that there will be a general response from business men. We shall have the privilege of publishing any or all of the contributions received.

Replies are to be received not later than April 29, 1893. They should be addressed as follows:

DAVID WILLIAMS,

96–102 Reade street,

New York.

Prize Competition No. 19.

The committee to whom the contributions in Prize Competition No. 5 were referred have awarded the prizes as follows:

First Prize to H. S. DRUMMOND, Newark, N. J.

Second Prize to CHESTER G. AMBLER, Danbury, Conn.

Third Prize to H. P. KING, Portland, Ore.

Other Competitions which have closed are now in the hands of the Committees of Award, who are giving careful attention to the claims of the different contributions. From the number of these and the evident merit of not a few of them, we are assured that a great deal of valuable information and suggestion will be put at the disposal of the trade.

The Weekly Prize Competitions noted below are now before our readers and remain open until the dates named:

No. 16. Closing April 8.

Three or More Rules to be Observed in Buying.

No. 17. Closing April 15.

How Merchants Should Treat Traveling Salesmen.

No. 18. Closing April 22.

The Extent to Which Merchants Should Devote Their Attention to Outside Interests.

No. 19. Closing April 29.

Electrical Goods as a part of a Hardware Stock.

Another subject will be announced in our next issue.

We were favored with a card of invitation to be present at the closing exercises of the New York Trade School. Later we hope to present a report of the proceedings which attended the presentation of certificates, as well as of the addresses given on the occasion. Four hundred and fifty-three students received diplomas of proficiency.

Says an English scientific journal when considering the question of utilization of city waste: The waste of a great city might easily feed its desperate poverty. We waste our coal and our smoke, our gas and our water, our food and our refuse. What we want is more forethought in times of comparative prosperity. The chemist turns scrap iron into ink, old bones into lucifer matches, the shavings of the blacksmith's shop into Prussian blue, fusel oil into oil of apples and pears, and drainings of cowhouses into fashionable perfumery, beggars' rags into new pilot coats, and tar waste into aniline dyes and saccharine. In Paris they first utilize rats to clear the flesh from the bones of carcases, then kill the rats, use up the fur for trimmings, the skin for gloves, their thigh bones for toothpicks, and their tendons and bones for gelatine wrappers.

The Bulletin of the American Iron and Steel Association is responsible for the following story illustrative of the economic methods of the guardians of Uncle Sam's purse: It is interesting to note, says that journal, the absolute accuracy which the Government requires before it will receipt for light-weight coin. Only a short time ago a consignment of gold was received at the Treasury Department from San Francisco. The gold came in heavy canvas bags, and in an aggregate of a quarter of a million dollars of gold it was found that it was 9 cents light in weight. The cashier of the Treasury had to make good the deficiency of 9 cents, but the bags themselves were sent to the assay office at Philadelphia, and at an expense of probably a hundred times the amount of light weight the bags were burnt, the gold was recovered from the bags by a smelting process and returned to the cashier, who in the end lost nothing.

PLUMBING AND GAS FITTING.

Device for Destroying Sewer Gas.

At the store of S. A. Maxwell & Co., 134-136 Wabash avenue, Chicago, is to be seen a device, invented by engineer John Green, for disposing of sewer gas by burning. The device has been in use for some time. It was suggested to Engineer Green by necessity. Maxwell & Co.'s pipe system was faulty, and the defects eluded many attempts made to discover and correct them. In the meantime the rooms of the building, especially the basement, were impregnated with sewer gas and various "bad smells," to a dangerous extent. As from the building's sewerage system and from the main sewer. It is forced into the fire through longitudinal openings in the square boxes and is burned up.

In Fig. 1 is presented a view of boiler showing the arrangement of pipes and boxes. A and B are the two air boxes which are placed on either side of the fire box, the brick being cut away so they will be flush with face of brick wall. They are also placed as near the boiler front as convenient. The distance from top of grate to openings in boxes is 12 inches. C D is the 3-inch pipe leading to the sewer. C E and D F are $1\frac{1}{2}$-inch pipes connecting the main supply pipe C D with syphons and air boxes. G H J K is the $\frac{3}{4}$ steam supply

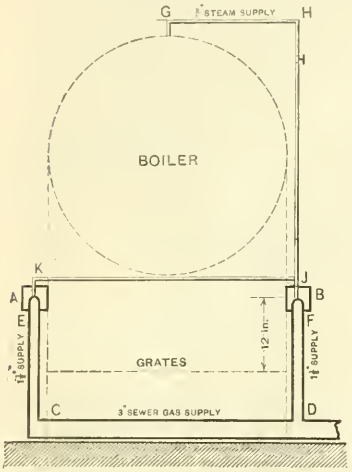

Fig. 1.—Front View of Boiler, Showing Arrangement of Pipes.

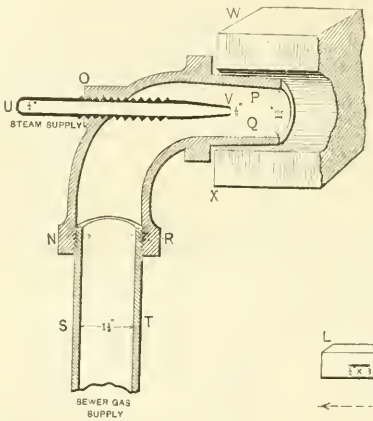

Fig. 4.—Section of Syphon.

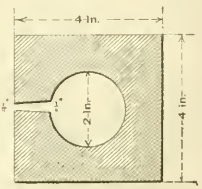

Fig. 3.—Section of Air Box.

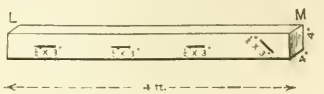

Fig. 2.—Air Box.

DEVICE FOR DESTROYING SEWER GAS.

is the case with many of the old style Chicago buildings, or those put up soon after the great fire, the exhaust from the engine is connected in the basement by means of a Y with the ventilating pipe which leads from the sewer up through the roof. Engineer Green is of the opinion that the result of this arrangement is either to force steam into the sewer, or at least prevent the escape of sewer gas up the pipe as intended. Hence he set about correcting this trouble, and invented the device referred to.

"There is no patent upon the device," said engineer Green. "All it cost was the expense of rigging up the boiler and running the connecting pipes to the sewer." The device comprises two iron pipes or boxes at the top and either side of the firebox of the boiler. A steam jet with an aperture of $\frac{1}{8}$-inch is screwed into the boxes. The latter are connected by 3-inch pipes with the sewerage system in the building, and the connection is also carried out to the street side of a trap opening into the large sewer under Wabash avenue. Steam is forced at a high pressure into the square boxes, the effect of which is to create a vacuum and a draft so strong as to draw in gas for syphons, and is connected with the boiler. One of the cast-iron air boxes is shown in Fig. 2. It is 4 feet long, and 4 x 4 inches at the ends. Four longitudinal openings, $\frac{1}{8}$ x 3 inches, are placed in the box, as shown. A 2-inch opening extends through the box, which is closed with an iron plug at M. The end L slips over the syphon. A section of air box is shown in Fig. 3. The longitudinal openings are $\frac{1}{8}$ x 3 inches outside, and $\frac{1}{4}$ x 3 inches inside. The top of opening is on an angle, the object being to cause the air to strike down on the fire. In Fig. 4 is presented a section of steam syphon and part of air box. N O P Q R is of cast-iron and made to receive the air supply pipe S T, which is indicated in Fig. 1 by E C or F D. U V is a piece of $\frac{1}{4}$-inch pipe drawn out so the opening at V is $\frac{1}{8}$-inch in diameter. U V is connected with the $\frac{3}{8}$-inch steam supply pipe as indicated at K or J in Fig. 1. The sewer gas supply pipes and syphons are placed inside of the boiler front, thus the only holes necessary in the front are those for the steam supply pipes, which can be placed outside.

The device having been tested by means of an anemometer, it was estimated that 3,840,000 cubic feet of sewer air passed through the pipes in one month. Engineer Green says the action of this device assists in the consumption of smoke, and he believes that in this respect it is as effective as many smoke burners of special make. The working of the device was explained by him to the Municipal Order League at a late meeting. He said that if the device was generally adopted manhole explosions would become a thing of the past. Engineer Green states that during January, 1892, before the device was in operation, 124,000 pounds of good coal were used, the plant being run during the day only. During January 1893, with the device in operation, 121,000 pounds of poor coal were used, the plant being run day and night.

The North Shore Plumbers' Association.

We have received from W. E. Goodwin, secretary, 714 Evanston avenue, Evanston, Ill., the following report of the organization of the new Master Plumbers' Association of the North Shore, which was effected at Evanston on March 23.

The initiatory degree was conferred by W. T. Geary, assisted by D. J. Rock, J. B. Breen, Alexander W. Murray, and Robert Thoroughgood of the National and Chicago Master Plumbers' Associations.

The members of the new association are Robert Thoroughgood of the Thoroughgood Plumbing Company, Rogers Park; J. J. Pickett, Evanston; John Eiden, South Evanston; Thomas Howe, Lake Forest; W. E. Goodman, South Evanston; George Wallace of George Wallace & Co., Evanston; Charles Wallace of the McDougle Plumbing Company, Evanston; A. Balfour, Evanston; Charles Beck, Evanston; Louis Beck, Rogers Park, and G. Specht, Wilmette. The officers of the

association are as follows: Robert Thoroughgood, president; J. J. Pickett, vice-president; Thomas Howe, treasurer; W. E. Goodman, secretary, and John Eiden, sergeant-at-arms. The towns included in this association are Rogers Park, Evanston, South Evanston, Wilmette, Winnetka, Highland Park, Lake Forest and Waukegan, lying north of Chicago in a rapidly growing district.

The leaders in this movement have assurances from all the plumbing firms in these towns that as soon as possible they will join, expressing themselves in hearty sympathy. Regular meetings are held on the fourth Monday in each month at Liberty Hall, Evanston.

Range Boiler Emptied Through Relief Pipe.

From E. P., *Stockton, Cal.*—In regard to the inquiry of "C. Q. A.," of Ohio, in *The Metal Worker* of March 18, respecting a range boiler emptied through a relief pipe, I would suggest that if he carried the vent pipe from the top of the boiler direct to the top of the supply tank he would not be troubled with the boiler emptying. The trouble is after the water becomes hot enough in the boiler it expands sufficiently to overcome the gravity of the water in the tank. If the tank was at a higher elevation there would be pressure enough to overcome the expansion of hot water in the boiler and the emptying would not occur.

From E. R. P., *Baltimore, Md.*—In *The Metal Worker* of March 18 and March 25 there appeared articles headed "Range Boiler Emptied Through Relief Pipe." In the issue of the 18th "C. Q. A." tells that such a thing is done, and in the issue of the 25th "W. T." explains why it is done, or rather the cause of the effect. Then "W. T." suggests three methods of overcoming the difficulty, the last of which would dispense with the relief or expansion pipe in the case of street pressure. I am of the opinion, as is "W. T.," that doing away with this portion would not bring about any dangerous results, and I would here raise the question why such a pipe is used in country houses, or wherever tanks supply the boiler. Last winter, which was a severe one, I have, in two cases, found the expansion pipe frozen at the tanks, which were under the roof and in the coldest part of the house. They were consequently rendered useless for expansion, while in the case of the supply pipe the occupant took the precaution of wrapping them to prevent freezing. This precaution would probably never have been taken had not their supply been cut off at all the outlets, and as the freezing of the expansion caused no inconvenience they never took the trouble to prevent the freezing. I therefore ask the question, What practical use are they, unless, perhaps, to prevent collapsing of the boiler (when not frozen), and if this is the only use what safeguard has a boiler against collapsing that is supplied by street pressure? I know that there are such devices as vacuum valves, but they are seldom used.

New York Plumbing Regulations.

From T. Y., *New Jersey.*—I wish to obtain a reliable book, giving illustrations, with the sanitary laws and regulations of the Health Department of New York City.

Answer.—The rules and regulations governing sanitary plumbing in New York City are published by the Building Department, corner Eighteenth street and Fourth avenue, and give only the necessary instructions, but no illustrations. Copies are supplied to plumbers doing work in the city who ask for them, and if our correspondent cannot apply in person he will have to get some friend to procure a copy.

TRAPS AND VENTS.

FROM A LOCAL PAPER published at Atlantic Highlands, N. J., we learn that Percy Falkinburg of that town has received a patent on an automatic flush tank for closets, which consists of an air-tight tank with a mechanical movement inside which causes the tank to fill with water when the closet is in use until the air pressure equals the water pressure.

THE KEYSTONE POTTERY COMPANY of Trenton, N. J., have just published a 14-page catalogue, covering their line of sanitary ware. It is printed on paper of extra quality, and the illustrations are tinted. Neatly bound in cloth, it will, no doubt, be very acceptable to the trade.

A DETROIT LOCAL PAPER gives an account of "Shipping a factory across the Atlantic," telling how the entire plant and equipment for the Steel Clad Bath Company's English factory was sent from New York. Presses and rolling machines of different descriptions will be erected immediately on their arrival under the supervision of James Hutcheson, formerly of the Detroit Company. The Steel Bath Mfg. Company have been doing a very excellent business, and their increase in trade has decided them to erect a new three-story building.

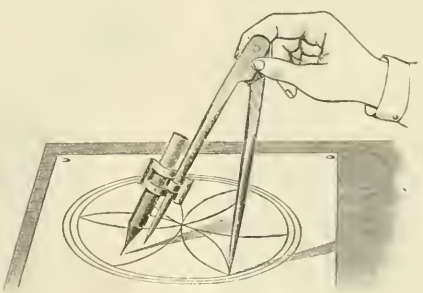
THE BEEKMAN SALUTARY SYSTEM COMPANY make announcement to the trade that they are closing out their retail branch at 56 Beekman street, New York. They mention that it has well served its end, in bringing the Whirlpool Closet and Beekman Duplex Tank prominently before the best architects, sanitary engineers and builders in the country. They now feel that they are in a position to confine themselves entirely to manufacturing this closet and tank and other sanitary specialties which they control, as was the intention of the company when incorporated. The Beekman System will hereafter be sold direct to the trade at close manufacturers' figures.

THE APPLICATION of cement to the construction of pipes was recently described in a French engineering journal. The method followed is what is called the Bordenave system of sidero-cement. The general principle consists in imbedding a frame work of iron bars in cement mortar. These bars are made in long lengths and wound in helical form. The working stress is calculated at 9.8 tons per square inch, so that for a pipe 2 feet 7½ inches, inside diameter, a bar 0.5 x 0.2 inches would have a pitch of 3.8 inches for a head of water of 33 feet. An experimental pipe line of four miles has been constructed on this principle and found to be entirely successful. The metal is said to be completely preserved from deterioration by the cement which adheres closely to it. Other advantages claimed for the invention are that no vegetation or deposit of any kind will attach to the cement; that the danger of leakage is less than in iron piping with lead joints, and finally, that there is a saving in cost over iron pipes of from 15 to 45 per cent., while the durability of cement piping is stated to be exceedingly good.

THE PECK, STOW & WILCOX COMPANY have commenced the manufacture of a line of Gas and Burner Pliers. These goods are referred to by the company as drop forged, solid steel, well tempered and polished, and fully warranted. The Burner Plier is made in 5, 6 and 7 inch sizes, the first two having one opening and the latter two sizes of grip. The Gas Pliers are made in seven sizes, 7 to 14 inches inclusive, with two sizes of openings and screw driver attachment on one arm. Both classes of Pliers have the usual grip for small work on the end.

Double-Grip Pencil Clasp.

Wm. H. Jacobus, 90 Chambers street, New York, is offering the above device, as illustrated herewith. The wedging action of the compass causes the clasp to grip the pencil rigidly, and a fine adjustment for the size of the circle is obtained by turning the clasp on the compass leg



Double-Grip Pencil Clasp.

The pencil may be easily adjusted in the clasp by loosening the clasp on the compass leg. The point is made that the clasp when attached to a pencil prevents it from rolling off the desk, and also serves as an eyelet for attaching a string. The clasp is made of rolled brass, nickel plated, and is designed for use on compasses or trammels, and for machinists, carpenters and draftsmen; also for use in schools.

The Effect of Melting Pig Iron.—The Valentine Iron Company of Bellefonte, Pa., have just issued the first number of a small publication called the *Nittany Bulletin*, which deals with their Nittany brand of foundry iron. From it we glean the following chemical data bearing on a recent experiment made by them to show the chemical change which takes place in the cupola. The following table shows the change in the chemical composition of iron as the result of remelting, the analysis given being that of the pig iron and of the resulting castings, one a heavy piece of machinery and the other a thin plate ¼ inch in diameter:

	Pig iron.	Large casting.	Small casting.
Silicon	2.080	2.400	2.380
Graphitic carbon	3.140	3.420	2.180
Combined carbon	0.740	0.100	0.430
Manganese	0.654	0.397	0.490
Phosphorus	0.508	0.530	0.502
Sulphur	0.041	0.089	0.097
Iron	92.230	92.850	93.130

The melt was made with a 48-hour coke having 1.46 per cent. of sulphur, which explains the increase in the sulphur contents in the casting.

The Pennsylvania Legislature has appropriated $625,000 for a fire proof State Library building.

ROOFING AND CORNICE.

The Country Cornice Shop.

VI.

By Cornice Worker.

MOLDED GUTTERS ON BRICK WALLS.

Fig. 47 shows the method of fastening a sheet metal molding to a brick wall, on which the gutter is formed of wood, and then lined with sheet metal. A is a section of the brick wall, the upper portion L being built up to but half the thickness of the wall, as shown, thus leaving a space on which to build the gutter, as shown at K. C represents the wooden wall plate, fastened to the wall by means of the bolt B, which has an angle at the bottom. The bolt is placed upon the wall when up as high as shown by the dotted line X. The wall is then built up around the bolt, after which a hole is made in the wall plate C and set over the bolt and fastened with a washer and nut, as shown. D represents the rafter on which the roof is planked, and to this the flange of the gutter lining is nailed. As all this has no bearing on the cornice work, it is only briefly explained so the reader may better understand the sectional views of this kind of work. In making the details for the molding and brace, shown in Fig. 47, care should be taken that the inside brace, shown from 1 to 5, is so drawn that a portion will meet the top member of molding at 1, at part of the ogee, as shown at 2, at the flat portion, shown at 3, and on the flange of the drip, shown at 4. Bolts are then inserted through the molding and brace, as shown at 1, 2, 3 and 4. The thickness of the wall A is taken and the brace made to extend through it, allowing for a flange to bend down behind the wall, as shown at 5. The length of the flange should be less than the hight of a brick. Care should be taken in drawing the top flange and lock of the molding that the lock J, Fig. 47, comes directly over the center of the gutter plank H, so that when the sheet-metal lock of the gutter lining is locked into J of the molding and pounded down with the mallet the blow will come directly over the center of the wooden plank H. If the lock J should come in further than the thickness of the gutter plank H, a bad seam would be the result, because the locks could not be driven together, there being no foundation to pound on. It will be noticed that that portion of brace in Fig. 47 which meets the ogee at 2 at once gives the shape of the gutter on the inside, against which the plank H is laid, as shown.

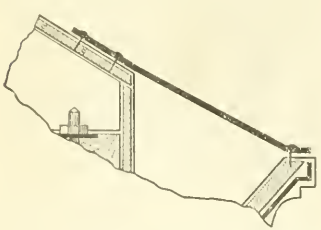


Fig. 49.—Part Section of Gutter, Showing Top Brace.

CONSTRUCTING AND SETTING UP THE WORK.

After the molding is formed on the brake, and set together to the required length, the braces are inserted about 30 to 36 inches from centers, care being taken that the length of the brace from R to S, in Fig. 47, is correct so as to slip over the wall.

The mason, when building up the wall, usually has a scaffold on the front, which is often used by the cornice maker to put up his work. One way to set moldings of this kind is to have the mason stop with his wall when he gets up as far as shown by the dotted line V, Fig. 47. The braces are put in the molding in the shop, with the flange S5 already bent. A hole is punched through the brace as shown at 5, in which to fasten the wire.

Now set the molding and braces upon the wall, and have the drip R of the molding fit well against the face of the wall, as shown. As the molding will

THE COUNTRY CORNICE SHOP.

have a tendency to tip forward when set, fasten a piece of wire in the hole 5 of brace, press down the brace at S firmly on to the wall, and fasten the wire with an anchor nail into the joint of brick work shown at 6. The wall L is now built on top of the braces, which holds the molding in its proper position. As the full depth of the gutter down to the wall K is not required, blockings of wood are placed upon the braces, as shown at E, Fig. 47. In gutters of this kind the carpenters should prepare the pitch of the gutter. F represents the lowest point of gutter, and N the highest; and after obtaining the required length of the gutter, the lowest point would be blocked up with wood to the hight of F, and the highest point blocked with wood as high as N. A chalk line is then stretched from N to F, and intermediate blockings placed. The gutter is planked out as shown by F F F and connected with the roof boards, after which it can be lined with either tin, copper or galvanized iron, locking the lining into the front lock on molding as before explained, and leaving a flange on roof of about 4 inches, as shown at O, which would be sufficient lap, whether the roof were covered with tin, slate or shingles.

It is the writer's preference in putting up moldings of this kind to let the mason and framer first finish their work complete. When the work is put up before, by the time the mason has finished his wall, and the framer has his wall plate and rafters set, the molding is usually pressed out of shape and flattened.

When putting up the molding after the wall is finished, set it temporarily against the wall and mark where the braces will come, so as to cut the holes shown from L to Y, Fig. 47. As before explained, the angle of brace S 5 should be less than the hight of a brick, so that the holes cut with the use of a chisel and heavy hammer through the brick wall need be the hight of one brick only. The braces having been slipped through are then drawn down with wire as before explained, and the mason closes up the holes with brick, thus holding the braces firmly in position. Y in Fig. 47 represents the leader to carry the water from the gutter. The back of the leader, laying against the wall, is carried up through the blockings, as shown by the dotted line, and intersects the gutter on the bottom line F. The front of the leader is run up through the molding and intersects the plank H at F. Now, if the leader was left in this position it would deface the entire front of the molding, so to overcome this a projection the width of the leader is placed over it, as shown at F', Fig. 47. This at once forms a leader or conductor head, the face of which is shown at E, Fig. 48. The projection 7 8 and 7 8, on either side of the leader F, Fig. 48, is the same as the projection 7 8 over the leader Y, Fig. 47.

Fig. 48 also shows a portion of front elevation of the molding G, which miters to the leader head E, as shown.

Fig. 49 is a part of Fig. 47 reversed, showing top brace fastened at top and bottom, to prevent the gutter from breaking down when filled with snow and ice. After the gutter is lined and the top lock is soldered water tight a galvanized-iron brace is screwed to the roof boards and into the plank of the front of the gutter, as shown. These braces are placed about 30 to 36 inches apart, and are made of $\frac{1}{8}$ x 1 inch band iron, the same material being used for the inside braces, shown in Fig. 47. The method of bending these braces was fully explained in a previous chapter.

Having now explained how the work is to be constructed and put up, we are in a better position to take the measurements and obtain the patterns.

OBTAINING MEASUREMENTS.

Fig. 50 is a rough sketch of the roof plan of a bay window showing the leader, projection of the leader head and angles of walls. The measurement for the moldings would be taken upon the wall line from A to B, B to C and C to D, the angles A B C and B C D being the same. The angle is taken with a bevel, as explained in a previous chapter. The angles at A E and D F are square. Two miter patterns would be required, one for the angle A B C or B C D and the other for the leader head shown in Figs. 47 and 48.

OBTAINING THE PATTERNS.

To obtain the two patterns for the miters, proceed as follows: Let A^2, Fig. 51, represent the section or profile of the gutter, shown at F', Fig. 47. Place the profile in its correct position, as indicated, having the line 12 13 of the profile A^2 perpendicular, and divide the profile into a number of parts, as shown. In line with 2 3 of the profile A^2 place the angle of the leader head, as shown by H I J or I J O in Fig. 50, which is a right angle, as shown by B A' C' in Fig. 51. Then again in line with 2 3 of the profile A^2, Fig. 51, place the angle of the wall A B C or B C D of Fig. 50, as shown by B A C in Fig. 51.

The next step is to obtain the miter lines of these two angles, for which proceed as follows: Place one leg of the compass at the point A', Fig. 51, and strike an arc, as shown from C' to B'. Now, with C' and B' as centers, strike the two arcs as shown intersecting each other at D' and O. A line drawn through these two intersections will be the required miter line, as shown from E' to A'.

The same method is employed for obtaining the miter line for the other angle. With A as center, strike the arc from C to B; then, with C and B as centers, strike the two arcs shown intersecting each other at D and J. A line drawn through D and J will be the required miter line, as shown from E to A, Fig. 51. When miters for different angles are required, and the profile is the same, it is well to use this method of placing the miter lines under one another, thereby saving considerable time in spacing the profile for each miter line.

From the divisions on the profile A^2 drop perpendicular lines, as shown, cutting the miter lines E' A' and E A. At right angles to the perpendicular lines draw the line H I indefinitely, upon which place the stretchout of the profile A^2, as shown by the small figures 1, 2, 3, 4, &c. At right angles to the stretchout line H I draw lines indefinitely from the small figures, which intersect with lines of corresponding numbers drawn from the intersections on the miter lines E' A' and E A parallel to the line H I. Draw lines through these intersections; then H I K J will be the miter pattern for the angle required for the leader head shown at E, Fig. 48; and L M N the miter pattern for the angle taken on the wall line A B C or B C D, Fig. 50. It will be noticed that the angle B' A' C', Fig. 61, is a right angle, and that the pattern obtained is for a square return miter. The method here shown is the long rule for obtaining square miter patterns, the short method having been explained in a previous chapter. It is the writer's preference always to use the short method; but when cases arise where miter patterns are required at other than right angles, and a plan must be drawn as B A C in Fig. 51, then we can just as well draw the plan of the right angle B' A' C', as but one operation is required to intersect any number of miter lines.

FULL SIZE PATTERNS.

Fig. 52 shows the method of cutting the full size patterns from a sheet of iron with as little waste as possible. Let A B C D represent a sheet of iron, upon which the patterns for the leader head are to be laid out.

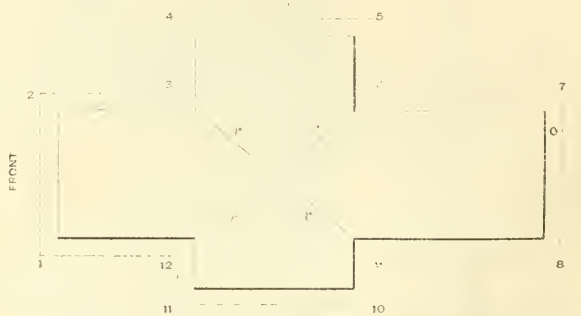
In practice, the front edge of the sheet A B would be cut straight, so that the lock would show an even edge when bent on the brake, and to which the lock of the gutter lining would be attached, as at J, Fig. 47. A stretchout of the profile A^2, Fig. 51, is now taken upon a strip of zinc about $\frac{5}{8}$ inch wide, upon which the bends of the moldings are dotted off. These dots are now transferred upon the sheet by placing the zinc stretchout even on the line A D, Fig. 52, and dotting off the sheet by means of a scribe awl and hammer. Horizontal lines are then drawn through these dots, which represent the bends of the molding. Next turn the pattern A of Fig. 51, and place the line 2 2 of pattern to correspond with the line 2 2 upon the sheet of iron in Fig. 52, and mark the miter, as shown, from H to I, with a scribe awl. Take the width of the leader Y, Fig. 47, and place it as shown from I to J on the line 15 15, Fig. 52; then, reversing the pattern A of Fig. 51, lay the point 15 of the miter upon the point J on the line 15 15, Fig. 52, and having the line 2 2 of the pattern upon the line 2 2 of the sheet of iron, mark the miter, as shown, from K to J. Then will K H I J or E of Fig. 52 represent the pattern of the face of the leader head shown at E, Fig. 48. As the bottom of the leader head is to be placed on the face E, Fig. 52, and the sheet of iron not being wide enough, a small piece of iron would be soldered on. At right angles to I J draw I S, equal in length to I J, and make a square, as shown. Draw the dotted diagonal lines, the intersection giving the center point from which to strike the circle corresponding to the diameter of the leader Y, Fig. 47, and which would be cut out with a circular shears or snips. This completes the pattern for the entire face and bottom of the leader head, laps being allowed as shown by the dotted lines.

Where the leader head intersects the moldings, as at H and O, Fig. 50, it is called an inside miter. Therefore the pattern A of Fig. 51 would be placed in such a position on the sheet of iron shown in Fig. 52 that L M would represent a reverse cut, or inside miter. As M N of Fig. 52 would be joined to I S, take the width of I S and place it as shown by M N and L O, and mark the miter cut. Then will L M N O or F of Fig. 52 represent the projection of the leader head, shown at F', Fig. 47, and the miter cut O N of Fig. 52 be connected to the face E on the cuts J K or H I. Now take the pattern A of Fig. 51, and place 2 2 of the pattern upon the line 2 2 of the sheet of iron and mark a reverse or inside miter, as shown by P R, Fig. 52. Allow laps, as shown by the dotted lines from P to R; then will A P R D or G represent a portion of the molding G, Fig. 48, on which the leader head would be joined, the cut L M on Fig. 52 being joined to P R of the same illustration. The measurement on the molding would be made upon the line R 15 of Fig. 52, that being the bend which sets upon the brick wall. Whatever more molding would be required to obtain the desired length would be joined to the piece G, Fig. 52, having the miter cut the same as B, Fig. 51, for the angles A B C or B C D, Fig. 50.

The face and the return of the leader head E and F, Fig. 52, could be formed upon the hatchet and mandrel stakes, using the ridge and gutter former to make the ogee. In forming the molding G, Fig. 48, it would be best to commence at the lock J, Fig. 47, bending it square with the mallet by using the brake previously illustrated, and then turning over the lock to its proper position with the use of the hatchet stake and mallet. The ogee and the square bends would be made as explained in a former chapter.

Roof with Single Leader Pipe.

From D. G., *New Hampton, Iowa*.—I would be pleased to have the opinion of *The Metal Worker* with regard to a matter which I will try to explain. Inclosed find outline plan of roof of a two story



Roof with Single Leader Pipe.

dwelling house 60 feet deep, the roof being about one-fourth pitch. The solid lines represent the eaves, the broken lines hanging gutter or eave trough. The figures 1 to 12 are 12 miters in the trough, eight outside and four inside. The size of the trough is 4½ inches. The entire run is 170 feet. The distance between 5 and 6 is 5 feet and between 9 and 10 3 feet. Please bear this fact in mind, as it may help to the solution of a difficulty made apparent further on; *v v v v* are four valleys terminating in four inside miters. O, at the southwest corner, is the only outlet and down pipe in the system. This job was put up last summer, and is not satistactory, as the water flows over at 5, 6, 9 and 10. The owner was particular that there should be but one outlet. I gave it as my opinion at the time that there would be serious trouble, considering the great number of right-angled miters in the trough, and experience proved that I was correct. I claim that the rush of water in the valleys, terminating in the short runs between miters 5, 6, 9 and 10, retard the uniform flow or dam it up, causing the water to flow over at those points. I apprehend also that no reasonable amount of fall would overcome this tendency to fill to overflowing. About the only thing, aside from more outlets, that suggests itself to me is a much larger trough and increased fall, the present fall being 6 inches. The proprietor avers that more than the present outlet is impracticable,

owing to no sewerage, nature of soil and close proximity to other property. Reconstruction is the word passed to headquarters, and I would like to have your opinion expressed through *The Metal Worker*.

Answer.—We think the last suggestion made by our correspondent is by all means the best, namely, to reconstruct the whole thing and put in more leader pipes. Of course the difficulty could be overcome by increasing the size of the gutters, as there must necessarily be a flow toward the outlet, and the only thing is to have the gutters of sufficient size to hold it, even though it be dammed up at the corners. The suggestion that the water flowing down the valleys forms an obstruction to what flows through the gutters from the other part of the roof is plausible, and we think explains the trouble. The water coming down with considerable velocity may flow against the opposite corner of the gutter and divide part of the stream backing up away from the outlet and necessarily damming the flow. A possible remedy that suggests itself would be to put in a deflector at the bottom of each valley which would throw the water into the run of the gutter so that it would not flow directly across and give rise to back water. The introduction of this deflector, however, would probably make it necessary to widen the gutter where it passes the bottom of the valleys. This might give a queer architectural effect, but would possibly prove a remedy and permit the owner to dispense with more leader pipes against which he has such an objection. We would like to hear from members of the trade in this matter.

FLASHINGS.

THE CANTON STEEL ROOFING COMPANY, Canton, Ohio, announce that their exhibit at the World's Fair will be located at Section H, Block 3, Space 14 in Manufacturers and Liberal Arts Building, near the northwest corner. They invite every one to call upon them, notwithstanding that their exhibit will not be as elaborate as intended, because of the very small space assigned.

THE CANTON STEEL ROOFING COMPANY, Canton, Ohio, issue a handsome illustrated catalogue, reference book and price-list of their manufactures. The volume, bound in dark green paper, with embossed gilt lettering, is of convenient size, and contains many hundred pages of text. On a separate sheet are printed directions for measuring the H. W. Smith patent folded lock seam steel roofing, also for iron doors and shutters. This style of roofing is thoroughly described in the early pages of the publication, together with illustrations. Next, attention is given to ventilators, the Monarch ventilator being illustrated in two styles. Paints of various kinds are noted; then corrugated iron in several varieties, also corrugated curved moldings and curved iron for ceilings and arches. Crimped iron, weather boarding, siding, beaded iron, sheet steel pressed brick, cluster shingles, &c., window caps, sills and jambs, hip coverings, chimney flashings and other articles are noted; and several pages are given to fire proof doors and shutters. The next section of the catalogue takes up eave troughs and conductor pipes, a very large variety being illustrated and briefly described, the material being stated and tables of dimensions given. Cut-offs and strainers are included in this section. Sheet metals are dealt in by this firm, and price-lists are given. Ornamental ridgings, crestings and finials, window caps, vanes, &c., complete the list of articles, while at the end is an index of the contents.

BERGER BROTHERS, 237 Arch street, Philadelphia, have issued their annual catalogue of Tinners' Hardware and Roofers' Supplies for 1893. The present issue is enlarged to 90 pages and contains a number of new goods, including a full line of registers, tinners' machines and Tools, and other fresh articles which have been added to Messrs. Bergers' extensive line of supplies. The catalogue is profusely illustrated, containing over 400 cuts of articles kept in stock. Special attention is called to Berger's patent eave trough hangers, which are stated to have become very popular with architects and builders; also to Berger's ornamental pipe straps, soil pipe, gas pipe and plumbers' hooks, and to the pail ears, saucepan handles and tinware trimmings, of which the firm handle a very comprehensive line. Berger Bros. announce that they have increased their plant, giving better office facilities and more storage room. The firm's Trade Discount Sheet for 1893 is forwarded with the catalogue.

AMONG newly licensed corporations in Illinois is the Sykes Steel Roofing Company, at Chicago, for the manufacture of roofing; capital stock, $50,000; incorporators, R. G. Sykes, C. O. Hart and H. G. Murphy.

Talks About Trade.

"I never miss an opportunity to have a social chat with a customer," said a Minneapolis merchant who asks not to be quoted personally. "Now please note, I say an 'opportunity' for a 'social chat.' First of all, every time is not opportune. Sometimes my customers are in a hurry, or I am in a hurry; or they are repellent in manner (though I do not let that disturb me very much); or some other cause arises to prevent my chat. Now, I also say a 'social chat,' but without meaning precisely a chat on social topics. My chat is always based, directly or indirectly, on the goods I handle. In other words, while taking an interest, and a very lively interest, too, in what my customer's wants are, I let him or her—say, principally, her—know that we can both be interested in and by other goods which she may not want at that moment. Of course such goods are in my line and in my stock—always. I take infinite pains to make her purchase the starting point of the conversation which (sometimes, I confess, by very indirect methods) will lead us up to the point where I can name new goods, point out novelties, tell of improved housekeeping helps and conveniences. In other words my 'social chat' is 'shop talk.'

"Do you know I won't permit a clerk to say in that stereotyped hand-me down fashion, with which as customers we are all wearisomely familiar, 'Anything else this morning, madam?' I believe in shop talk, but I know also that the ordinary 'shop talk' is a nuisance and a bore to all save a few silly women and soft-pated clerks who have mastered a certain jargon which they think will appeal to the women whose trade they wish to win. I carry a general line—all kinds, I might say, of housekeeping supplies. There is not a week in the year but what I have something new in stock.

"Now I don't want a clerk to make himself interesting to my customers; I want him to make my goods interesting, and if he can't do that I have no place for him. There are scores of clerks in this town in demand because it is believed they carry trade with them. In many cases there is too much of the aroma of the 'masher' in the atmosphere around these young men. If I ever get one of them on my pay roll he either reforms (and reformation in such cases is as rare as a thunder storm in midwinter) or he goes—quick. The best clerks I have ever had are men whose chief interest lies not in themselves, but in the goods they sell; men who inform themselves about the stock and can give the customer not merely the points of value in the goods but the reasons why they are points of value; men who talk the goods as if they believed in them and loved them, and men who can, therefore, interest a customer because they themselves have the unction and the influence that come from enthusiasm in their business."—*The Hardware Trade.*

SCRAP.

THE MANAGERS of the New Castle Tin Mill of New Castle, Pa., have just ordered an improved automatic pickling machine. This machine is manufactured in England. The engines and other machinery for the new plant are arriving every day, and the mechanics are placing them in position. The managers of the mill confidently assert that tin will be made in New Castle by June 1.

WORK OF REMODELING the old Malleable Iron Works, at Youngstown, Ohio, will be commenced shortly, preparatory to the starting of a tin plant by a company known as the Youngstown Tin-Plate Company. The machinery for the plant has all been bought and is now ready for shipment. The proprietors expect to put the plant in operation in about a month. Two Morewood machines will be placed in position and worked night and day; they will have a capacity of 35 boxes of bright tin and 8 boxes of terne plate every 24 hours. The men who have interested themselves in this enterprise have worked in tin mills on both sides of the Atlantic. The officers are: Samuel Thomas, president; David T. Edwards, secretary and treasurer; Joseph Chapman, superintendent.

THE NEW SHEET AND TIN MILL of the Falcon Company at Niles, Ohio, is being hurried to completion. The machinery of one of the sheet mills is being run to "limber" it up, and the intention is to commence rolling iron full turn Monday. A large force of men is at work, but it is not expected to have the tin mill ready for operation in less than two months. The plant is said to represent an outlay of $500,000, and will give employment to 350 persons. It is so planned that if the tariff on tin plate is disturbed so that American manufacture is made unprofitable, most of the plant can be operated as a sheet mill. It is equipped to roll the widest sheet of any mill in the country—55 to 60 inches across.

IN *The Metal Worker* of March 25 we printed a description and illustration of a galvanized iron vase made from scrap metal by William A. Wittbecker, Lansing, Iowa. In a recent letter from Mr Wittbecker he states that he has received so many letters of inquiry for patterns for making the vase, that he has decided to get up a carefully prepared set, with printed instructions, and will sell them, post paid, for 50 cents.

W. E. LOVEGROVE distributes cards, calling attention to his business at 939 Westminster street, Providence, R. I. Mr. Lovegrove works in tin plate, sheet iron, copper and zinc. He also does plumbing and gas fitting, furnace setting, roofing, &c.

House Warming.—VIII.

CHEMISTRY OF COMBUSTION.

The next branch of our subject which it will be necessary to consider is that of the chemistry of combustion, together with such physical laws as relate to it directly, and also incidentally, in connection with its effect on ventilation and sanitation.

Combustion, of whatever form, is a purely chemical phenomenon, and it is, therefore, governed by laws which are absolutely exact and unchangeable, irrespective of existing conditions, though, of course the latter will affect the rapidity or intensity of the combustion, as well as its degree of perfection.

Broadly stated, the terms combustion and oxidation are synonomous: combustion is oxidation and all oxidation is combustion, whether it be the rusting of iron, the purification of our blood by respiration, or the production of the most intense heat in a steel furnace. The burning of Chicago was the rapid oxidation of the combustible portion of the materials of which the buildings were composed; and the function of breathing effects the slow combustion of the impurities contained in the venous blood in its passage through the lungs, after having been the rounds of the entire circulatory system.

Were we considering the subject of heating alone we would need to investigate only the rapid oxidation or the combustion of fuels in the production of fire; but, as before mentioned, the sanitary phase of the matter demands that we examine into the requirements and effects of the less rapid rate referred to.

ELEMENTARY LAWS.

All chemical combinations occur in certain fixed and unvarying proportions of the different elements; and these quantities, although designated by volumes, or equivalent in the chemical formulæ and symbols, are really based on the weight (in vacuum) of a single volume, as compared with that of an equal volume of some other element. As hydrogen is the lightest of all known bodies, it is usually taken as the unit or basis of comparative weight, and from this unit the respective weights of light volumes of all other elementary bodies are calculated. These—called "atomic weights"—will be necessary in our calculations, and are given in Table XXI, as are also the symbols by which the elements and their several combinations, necessary to our purpose, are designated.

The first five items in the table, it will be noticed, are represented by symbols of a single initial letter, which indicates that they are simple elements. All of the items following employ different groupings of these letters or symbols, some of which are accompanied by numbers. These latter are all combinations or compounds of two or more of the elements, and their compositions are expressed by the groupings of symbols and figures which constitute the chemical formulæ by which they are invariably represented. Carbonic oxide, or carbon monoxide, for instance, is written CO, and means that one equivalent or volume of carbon and one of oxygen have combined to form this gas.

Referring to the table, we find the atomic weight of carbon to be 11.97, and that of oxygen 15.96; therefore, the formula would express that 11.97 pounds of carbon had combined with 15.96 pounds of oxygen to form 27.93 pounds of carbonic oxide.

But we see that carbonic acid is represented by CO_2, and we must know the meaning of the figure to understand the formula. All such figures placed to the right of the elementary symbol, below the line, are called indexes or indices, and indicate the number of volumes of the element entering into the combination.

Our formula, then, should be read: One equivalent or volume of carbon, weighing 11.97 pounds; and two volumes of oxygen weighing $(15.96 \times 2 =)$ 31.92 pounds, combine to form 43.89 pounds of carbonic acid.

In the case of olefiant gas, we find both carbon and oxygen have the index number, and C_2H_4 expresses $(11.94 \times 2 =$ 23.88 pounds carbon$) + (1 \times 4 =$ 4 pounds hydrogen$) =$ 27.94 pounds olefiant gas. In the case of sulphurous acid, we see the formula $H_2.SO_3$ is a combination of three elements—hydrogen, sulphur and oxygen. It will be noted that the H_2 is separated by a period from SO_3, which means that two volumes of hydrogen have united with a combination of one volume of sulphur and three volumes of oxygen, resulting in 81.86 pounds sulphurous acid gas.

Again, in the case of sulphuric acid, H_2SO_4, we see that the only difference will be one volume of oxygen, but our quantity of the acid will be $81.86 + 15.96 =$ 97.82 pounds.

We find atmospheric air represented by $N_4 + O$, and not N_4O, as in the previous cases. The reason for this distinction is that air is not in any sense a chemical combination, but is a purely mechanical mixture, in which the two elements, nitrogen and oxygen, in the proportion of 4 to 1, although very thoroughly mingled, are readily separable without involving any chemical reaction such as would be necessary to separate the oxygen and hydrogen, of which water is composed, and when they are in chemical combination.

It will be observed that the table shows the atomic weights of all the compounds named to be the sum of the weights of their constituents—that is, their atomic weights multiplied by the number of volumes. Thus H_2O gives $(1 \times 2) + 15.96 = 17.96$ as the atomic weight of water; and $H_2.SO_3$ gives $(1 \times 2) + 31.98 + (15.96 \times 3.) = 81.86$, atomic weight of sulphurous acid.

It is important to note, however, that, although the weight of a compound is the sum of those of the constituent elements, the volume after combination will always be governed by the number of elements, regardless of the number of equivalents of each. Thus, to find the number of cubic feet in one pound of a simple element, we divide the volume of 1 pound of hydrogen (at 62° F.) by the atomic weight of said element—as, for example, the atomic weight of oxygen is 15.96, and $\frac{189.7}{15.96} =$ 11.88 cubic feet per pound, as per column, 5 of table. For a compound—say olefiant gas—we see C_2H_4 gives a total of 6 volumes, and the atomic weight, 27.94; yet the number of cubic feet per pound will be 189.7×2 (the number of elements only) and divided by 27.94 or $\frac{189.7 \times 2}{27.94} =$ 13.587, as per table.

In the case of sulphurous acid, having three elements and six volumes $(H_2.SO_3)$ we have $\frac{189.7 \times 3}{81.86} = 6.4364$ cubic feet per pound. To find the weight in pounds per cubic foot, we divide 1 by the number of cubic feet in 1 pound, as $\frac{1}{6.4364} =$ 0.15536 pound = the weight of 1 cubic foot of sulphurous acid gas; or $\frac{1}{189.7} =$ 0.00527 = that of hydrogen, as per column 4 of table.

Table XXI.—Atomic Weights, &c.

Element or compound.	Symbol.	Atomic weight.	Weight per cubic foot at 62°.	Cubic feet per pound at 62°.	Specific gravity at 62°.	Relative density.

According to an English journal, a true copper age has been established. At a recent meeting of the Académie des Sciences, Paris, M. Berthellot read an interesting paper on the archæological question whether there was an age of copper prior to the age of bronze. Pieces of copper have been unearthed by M. de Sarzec in Mesopotamia which are apparently older than any found in Babylon and more ancient than the celebrated vulture steel of Chaldea. Copper is easily reduced from its ores by carbon, but bronze requires the addition of tin, a comparatively rare metal, as it is chiefly found in Malacca and Cornwall. Its use, therefore, implied the power of making long voyages and a considerable advance in civilization. M. Berthellot has analyzed the Mesopotamian specimens and finds them to contain no tin or zinc and only traces of lead or arsenic. Air and water have oxidized the specimens to a mixture of protoxide and metallic copper. M. Berthellot is also analyzing a portion of a scepter of one of the Pharaohs of Egypt who reigned about 3500 years before Christ, and so far he has discovered no tin. Of course, a large number of specimens will require to be analyzed before the question of a pure copper age is really settled, but his researches are in favor of the supposition. We may add that Prof. Flinders Petrie has adduced much evidence from Egypt in favor of a copper age.

An investigation of the affairs of the bankrupt Lombard Investment Company of Boston is said to show how a concern enjoying high repute may at the same time be entitled to no higher commendation than that of rare skill in deceiving the stockholders.

THE RETAIL STORE.

Local Advertising.

There is a great difference of opinion among retail Hardware merchants as to the most effective method of advertising their business. It is a recognized fact that bright, judicious newspaper advertising produces good results, while dodgers or gutter snipes are considered by many to be worthless as an advertising medium. Regular customers need to be frequently reminded that they can purchase goods to better advantage where they are in the habit of trading than at some other store where they may happen to drop in. Live merchants stimulate trade at dull seasons of the year by offering special inducements in certain lines. The stereotyped form of notice attracts little if any attention in these stirring times, and something striking, which will instantly rivet attention, must take its place. The manner in which this was done in one case may be suggestive to some of our readers. A firm in a Western city prepared themselves for a large business in tools by providing sufficient stock in this line to meet all demands, and then sent the following postal card by mail to mechanics whose names were selected from the city directory :

WE HAVE BEEN ACCUSED

Of maintaining the Best and Cheapest place in the City whereat to buy

HARDWARE.

We are now making a Special Sale of PLANES, SAWS, CHISELS, AUGER BITS, BRACES, SQUARES, HAMMERS, HATCHETS and Everything in the TOOL line at Reduced Prices, for Thirty Days. Call and see us.

CASE & UEHREN.

TERMS CASH. 29 River Street.

We are advised that the results were entirely satisfactory, a good many inquiries having been stimulated and a demand created for those goods.

Famous Parer and Slicer.

The paring and slicing knife which the accompanying cut illustrates is being introduced by Charles F. Spery, Herman, Mo. The knife is made of one piece of refined steel, providing two blades, one for cutting and the other for paring and slicing. The point of the knife is designed to remove the eyes of potatoes and the side of the blade to remove the decayed parts of fruits or vegetables. The point is made that the construction of the blade enables following the curves or uneven surfaces of the fruits or vegetables upon which it is used, as well as straight surfaces. The maker claims that by the use of the knife 5 to 10 per cent. of the peel is saved, and equally as much time ; that the forefinger is not made callous or the thumb cut; that an even peel is taken off and that the blade is easily cleaned. It is designed for use on potatoes, carrots, parsnips, turnips, squash, apples, pears, quinces and firm peaches.

Famous Parer and Slicer.

MEMORANDA.

CHARLES E. BOND died at his home in Pavilion, N. Y., March 21, after a brief illness. He was the youngest son of the late Elias Bond, one of the earliest settlers of Genesee County, and was 42 years of age. He conducted a hardware business in Pavilion for a number of years, and had served as postmaster and town clerk. He leaves a widow and four children.

CHARLES H. BOWNE of Gouverneur, N. Y., has sold his hardware store to Charles Loveland of Potsdam, N. Y., and will give possession at once.

WILLIAM MERRITT is about to open a tinsmith shop on Canal street, Hinsdale, N. H. He was at one time associated with Edward Stebbins, but for the past few years has been in business in Northfield, Mass.

THE HARDWARE STORE of F. B. Karl, located at 158 North Main street, Delaware, Ohio, was visited by fire on the morning of Saturday, April 1, resulting in slight damage, which was fully covered by insurance.

A. L. BURTIS, who for ten years has been in partnership with John Lambert at Lockport, N. Y., has started in business by himself at 41 Pine street, that city, and is prepared to do all kinds of work in sheet metal, as well as put in warm air furnaces. Mr. Burtis has been for over 30 years almost daily in the tin shop and is therefore most excellently equipped for his new venture, in which all his friends will wish him success.

WHITCOMB, KIRKHAM & HAZEN is the style under which will be conducted the business heretofore carried on by C. S. Whitcomb and Kirkham & Hazen at Springfield, Mass. The firm will begin business on May 1, occupying the old stand of W. L. Wilcox & Co., who just 30 years ago succeeded A. M. Galpin at the same location. C. S. Whitcomb of the new firm began the stove business 33 years ago, when he entered the employ of Mr. Galpin, then a leading stove dealer. Mr. Whitcomb followed the business through numerous changes, and finally in 1876 accepted a place with Leonard Clark. Two years later, however, he began business for himself, and has since been located at 150 State street. Mr. Kirkham of the new firm began in the stove business as a clerk for W. L. Wilcox & Co. in 1880, and six years later formed a partnership with George L. Esterbrook, which continued for three years. He then took E. C. Hazen as a partner, and the business was carried on under the name of Kirkham & Hazen. Mr. Hazen had previously been engaged in the business, and was several years a member of the firm of Simpson, Clark, Clark & Co. We understand that all three members of the firm are favorably known to the trade and have a thorough knowledge of the heating business.

Housewives' Delight Can Opener.

The accompanying cuts illustrate a can opener being put on the market by F. E. Kohler & Co., Canton, Ohio. It is described as being made from the best malleable iron, with steel knives adjustable to any size of can, and as cutting smoothly and without exertion. It combines openers suitable for round and square cans with a skewer puller, as shown in Figs. 1, 2 and 3.

Fig. 1.—Housewives' Delight Can Opener.

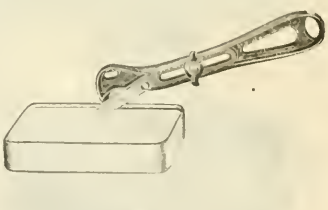

Fig. 2.—Adapted to Square Cans

Fig. 3.—As Skewer Puller.

Gem Cake Pan.

North Brothers Mfg. Company, Lehigh avenue and American street, Philadelphia, Pa., are offering the set of pans and cup as herewith illustrated. The pan, Figs. 1

Fig. 1.—Gem Cake Pan.

and 2, is in two pieces only, the side being removable from the bottom, and is made of extra quality heavy bright plate. As seen in Fig. 2, the rim on the bottom of the pan is so made that when the sides are pushed on the bottom it is tight, and the

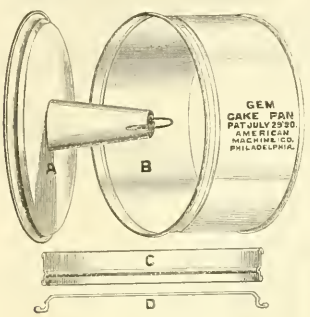

Fig. 2.—Gem Pan Apart.

makers claim that no batter can leak through or get in the joint. It will be noticed from letter D that the bottom of the pan where the cake rests is above the

Fig. 3.—Layer Pan and Measuring Cup

rim which supports the pan in the oven, so that the cake is elevated from the oven, to prevent its burning. The layer pans, Fig. 3, of which there are three in the set, come apart in the same manner as in the pan shown in Fig. 1, and are constructed upon the same principle. The cup is for measuring flour, sugar, &c., in receipts furnished with the set of pans. The pans are for baking delicate and other cakes without greasing the pans, and for removing the cake from the pans without tearing or breaking. It is explained that the pans permit of inverting the cake to cool when taken from the oven; prevent the cake from falling, and make cake larger and lighter than the ordinary style pan.

Retailers' Trade-Marks.

It is often found desirable by merchants to associate their names in the minds of the public with a peculiar typographical arrangement, as an effective form of advertising. This is done by

Fig. 1.—Stationery Size.

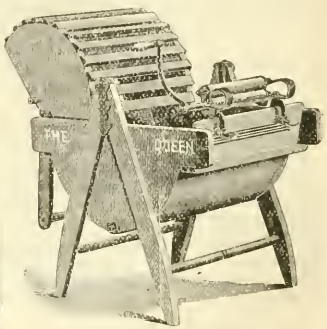
Samuel H. Blackwell, Fairfield, Maine, by using a trade-mark of white letters on a black background in various sizes, combining in an ingenious manner the words Blackwell and Hardware. Reproductions of the trade-mark in two sizes are given in the accompanying cuts, showing the happy way in which this is accomplished. It appears singularly fortunate that the name is Blackwell, and that the business engaged in is Hardware, which combine so happily in the typographical arrangement shown. The smaller sized trade-mark is printed upon letter heads, business cards, checks, receipts, memorandum

Fig. 2.—For Circulars, &c.

blanks, &c. It is also printed upon gummed paper for pasting on everything that goes out of his stock, and for sticking on circulars of manufacturers and jobbers, which he distributes to his customers. The larger size, Fig. 2, is used at the bottom of circulars of goods upon which special efforts are being made, printed for home use. Circulars of this kind, one devoted to each article, with the article illustrated on it, relate to Pocket Cutlery, Bucket Pump, Mixed Paints, Washing Machines, &c., with plenty of space below the description to print the large trade-mark. This is also used in newspaper advertising. The trade-mark is used for road-side signs also; for this purpose the words cover 8 x 17 inches of paper. It is glued upon smooth boards and afterward varnished to render it water proof. These boards are then nailed upon trees and buildings where they can be seen by people passing. These are much cheaper than painted boards and give satisfactory results. The goods carried in stock include Hardware, Iron and Steel, Cutlery, Cordage, Glazed Windows, Doors, Sash and Blinds, Farmers' and Mechanics' Tools, Kitchen Furnishings, Artists' Materials, Paints, Oils, Varnishes, &c., but are all grouped under the one word, Hardware, and by the method described are associated in the minds of the people in and about Fairfield with the name of Blackwell.

The Queen Washing Machine.

The accompanying illustration is of a washer being put on the market by the Buckeye Churn Company, Sidney, Ohio. It is explained that the slats for rubbing are semi-circular quadrilateral in shape, with their inclines running from the extreme points of the rubber toward the center, with sheet-metal lining covering over half the slats; and that in the tub the slats are of similar form, with their incline running from the center of tub below toward the top. Thus, when the rubber is in its place, resting on the goods, the inclines are in opposite directions. It is claimed that by every motion of the lever



The Queen Washing Machine.

the goods are moved in opposite directions; and reversing and dipping, as in filling and pressing a sponge, the sheet-metal lining over the rubber slats giving force to the water. These are some of the features claimed as being of especial advantage; also, that there is less friction on account of taking hold of the goods and not slipping over them. The manufacturers state that they are substantially made, rapid in operation and will not tear the clothes.

The New York Tack Puller.

The accompanying illustration is of a tack puller, put on the market by Maltby, Henley & Co., 20 Warren street, New York. It consists of a high-grade steel plate riveted on to a japanned iron handle, 6 inches in length. In operation the steel point at the top of the puller is forced under the tack, and by a downward pressure of the handle the tack is drawn. The point is made that the tempered steel point, by its peculiar construction, is stronger and more durable than forged steel, and that it is better adapted for the purpose of pulling tacks than ordinary tack claws.

The New York Tack Puller.

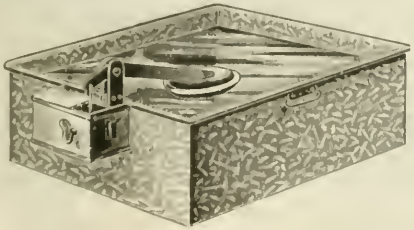
The Wayne American Washer

The Anthony Wayne Mfg. Company, Fort Wayne, Ind., are putting an improved form of washer on the market, as illustrated herewith. The difference between this and their Anthony Wayne washer consists in the American being wide on the bottom instead of on the top, as in the former. In this machine, it is stated, no nails are used inside the machine where they would be apt to come in contact with the clothing, and all nuts, washers, bolts, &c., that are used inside the machine are galvanized. The machines have solid corrugated staves and bottoms, which obviates the necessity of nailed cleats. The cover is hinged, and when thrown back lifts the gearing and inside working parts out of the washer.

The Wayne American Washer.

The Gurney Alarm Catch Basin.

An illustration is herewith given of an alarm catch basin for refrigerators and ice boxes, manufactured and sold exclusively by the Gurney Refrigerator Company of Fond du Lac, Wis. It is made of heavily galvanized iron, with an alarm attachment to be kept wound up. Connected with the alarm is a float, which rests on the surface of the water in the basin. As the water reaches a certain hight it automatically raises the float and starts the alarm, which calls attention to the threatened overflow, and thus prevents the ruin of carpets, or the injury of ceilings below.



Gurney Alarm Catch Basin.

The device is especially useful in connection with refrigerators having the waste pipe in the back, where the catch basin cannot easily be seen. It is made in two sizes, with a capacity of 12 and 16 quarts, respectively.

Columbia Hose Mender.

J. W. Lander & Co., East Greenwich, R. I., are introducing through Alford & Berkele, agents, 77 Chambers street, New York, the hose mender herewith illustrated. By means of the right and left hand screw of the mender the ends of the hose are brought firmly together, and thus made ready for the clamp. The clamp is referred to as a feature peculiar to this mender and as a great improvement over wires used for completing the joint. The clamp is in two parts and requires only a screw driver in adjusting it. Insuring, it is claimed, a perfect joint and preventing the hose from splitting at the ends where it has been mended. The menders are made in ½, ¾ and 1 inch sizes.

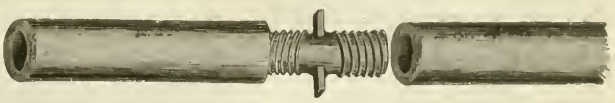


Fig. 1.—Columbia Hose Mender.

Aluminum Cooking Utensils.

A statement regarding aluminum cooking utensils, made by Joseph W. Richards of the Metallurgical Laboratory, Lehigh University, Bethlehem, Pa., in a letter to the Illinois Aluminum Company, Lemont, Ill., is given herewith. This statement is of interest to the trade, as it is the result of two years experience, and is as follows:

Speaking from an actual experience of two years with aluminum cooking utensils, I can state unreservedly that in point of lightness, cleanliness, durability and all-round adaptability to their purpose they leave nothing to be desired. They are the perfection of cooking utensils. As to durability, let me cite an instance:

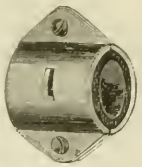

Fig. 2.—Hose Clamp.

Two aluminum boilers have been used in our kitchen for cooking all sorts of food in all sorts of ways, preserving, stewing fruit, etc., for two years. They have been used, washed, rubbed once, twice or three times a day for that time. They look as good as they did a week after we received them. Weighed on March 14, 1892, they weighed 1 pound 12½ ounces and 1 pound 11 ounces, respectively. Weighed to-night on the same scale they turn it to exactly the same weight, not a fraction of an ounce less. They both look good for many years' service.

The Monroe Refrigerator.

The Monroe Refrigerator Company, Lockland, Ohio, claim to have made some radical changes in the method of securing a low temperature in their large sizes of refrigerators without the use of crushed ice or melting the ice by salt or other artificial means, but with the greatest possible economy in the consumption of ice.

By their new system of refrigeration they claim to carry the cold dry air directly from the ice to the lowest parts of the refrigerator before it enters the provision compartments, thus securing a very low temperature at a great distance from the ice. It is explained that with their new system of refrigeration there is no passing of air, as the entire movement of the air in the provision compartment is upward, and there is never any mixture of flavors or tastes, and that if cream, milk and other delicate foods are placed at the bottom of the refrigerator, they received the pure, dry cold air directly from the ice before it touches other food. This system of refrigeration and dry air circulation is used in connection with their patent glazed earthenware lining, which it is claimed is free from absorption and metallic poisons therefore as cleanly as a dinner plate.

The Mexican correspondent of a contemporary reports that, as a result of the recent excursion of American manufacturers into Mexico, a number of prominent firms have established agencies in the City of Mexico. Others have purchased considerable tracts of coffee and agricultural lands, which they intend developing.

Effective Wall-Case Displays.

The Springfield Hardware Company, of Springfield, Ohio, advise us that they endeavor to arrange goods, especially those which bear a good profit, in so effective a manner as to claim the attention of customers entering their store. The accompanying illustrations give an idea of their manner of doing this, and indicate that they believe the time and labor required is well expended. A wall case near the entrance is devoted to Cutlery and fancy goods, as shown in Fig. 1. First are Knives and Forks, sampled on the original boxes, standing on shelves and so arranged as to present a uniform appearance. In the next apartment are Razor Strops, Razors, Shaving Brushes, Key Chains, Ticket Punches, Police Nippers, &c. In the next space are arranged Scissors and Shears, the larger ones in the center diminishing in size toward the edges. Razors occupy the corners at the top. The next opening contains Razor Strops, Brushes, Razors and Traveling Toilet Sets. To the right of these, though not shown in the cut, are shelves containing Table Cutlery, arranged to correspond with the shelves at the other end of the case. This arrangement of the case results in Table Cutlery on shelves at each end, and three apartments with glass sash in the center, making a pleasing and uniform appearance. The part of the center showcase nearest the door contains Scissors and Shears arranged in piles, one Shear on the top of the other. These are held in place by upright wire pins passing through the openings in the handles. The other part of the showcase contains Pocket Knives, sampled on their original boxes. Fancy Tea Kettles, Stands, &c., are shown on the top of the showcase, and also above the wall case. Another wall case, as shown in Fig. 2, is devoted to Bicycle Locks, Guns, Revolvers, Fishing Tackle, Dog Collars, Whistles, Calls, Wrenches, Jointed Rods, Nets, &c. Above these are Fishing Poles suspended by cord from the platform above, Fig. 3. Electrical goods are displayed in a section of shelving, Fig. 4, with a battery bell and push button in working order. Planes are shown, in Fig. 5, on inclined shelving with rods in front to prevent them from sliding off. These are adjoining the shelving containing the Electrical goods. Shelf Hardware is sampled on wooden shelf boxes, while under the ledge are drawers for Chisels, Braces, Squares, &c. The business was established in 1840 and incorporated in 1890.

Fig. 1.—Display of Cutlery and Fancy Goods.

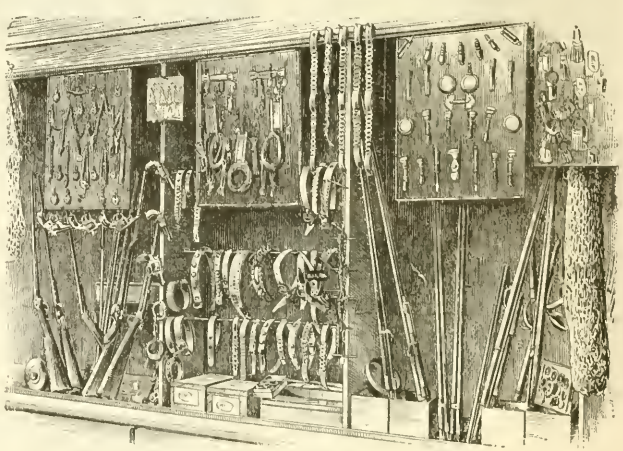

Fig. 2.—Sporting Goods, Fishing Tackle, &c.

How to Keep the Store Neat and Clean.

FIRST ARTICLE.

By M. W. Carleton.

That Hardwaremen in general are noted for their enterprise and intelligence is a fact generally recognized, and for this reason it seems strange that so large a number of them are negligent of the arrangement and cleanliness of their storerooms. A great many of them who have scrupulously clean, neat and tidy houses, and who would quickly find fault at any breach of the laws of order therein, will permit their offices and storerooms, in which they probably spend more of their time, to become so untidy and unclean as to cast reflection on the entire craft.

The fact is, the old proverbs, "Cleanliness is next to Godliness" and "Order is Heaven's first law" are as applicable to the Hardwareman as to his fellow merchant in any other line of business. That it is possible to have a Hardware store almost if not quite as attractive as that of the clothier, dry goods man, or even the jeweler, may be demonstrated by a visit to a store of the modern class, such as are happily becoming quite common in most localities.

When the actual advantage, attractiveness and economy of such a store is seen, it is a cause for wonder that these facts are not more generally recognized by the Hardwaremen, who, of all others, have the reputation of being the most progressive and ready to adopt any advanced business methods. So, laying aside all moral and social considerations, it seems strange that there are so many stores of the "good (?) old kind" in existence at the present time.

OLD FOGY.

Comparing one of these with one of the modern, progressive class, the contrast is startling and the advancement of late

years, especially of the last decade, very noticeable. In locating a storeroom of the former class the size is one of the principal considerations and such matters as light, ventilation and general arrangement are of minor importance. The shelves and counters are inconvenient, rough and unattractive features: the show windows entirely too small; the floor of wide pine boards, often warped out of shape, while Nail kegs, case goods, Agricultural Implements, &c., are disposed around the room with little regard for anything but convenience. Such a store as this can scarcely be made presentable even at the expense of prodigious labor. In contrasting the modern store the difference is such as ought to make even an "old fogy" a convert to the new *regime*.

Fig. 3.—Samples of Fishing Poles.

PLENTY OF LIGHT.

In place of the plain, open shelves with untidy rows of goods, and the old, unsightly counters with the rows of Nail kegs alongside, there are the attractive, cleanly rows of drawers with the samples advantageously displayed on the background of green or black, and the broad, oak counters with the convenient bins for Nails, &c., beneath.

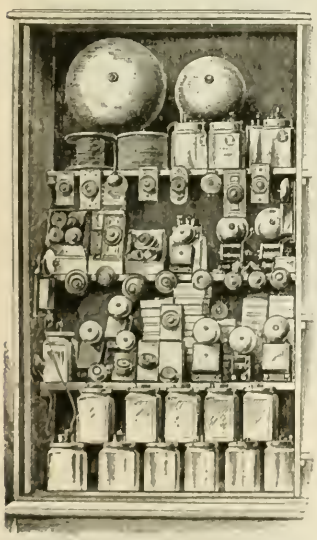

Fig. 4.—Electrical Goods.

By these arrangements two of the principal causes of untidiness, viz.: the open, dusty shelves and the unsightly Nail kegs, are obviated. Another great improvement is the racks or brackets for Steel Goods, Shovels, &c., by means of which these articles may be suspended from the ceiling or wall, leaving the floor entirely accessible to the broom. The Stoves carried in stock are placed on trucks and may readily be moved for sweeping or display. Then the little untidy show case with its seldom-changed assortment of Knives, Scissors, Revolvers, &c., is superseded by a larger and more attractive one, with effective display arrangements, while still another improvement of much importance is the windows of large, clear glass, admitting plenty of light and dispelling the gloom usually found in so many stores of the older class.

ATTENTION TO CLEANLINESS.

So much for arrangement, for in that lies half the solution of the problem, but it is not the other and usually neglected half by any means, since no convenience of arrangement or elegance of fixtures can compensate for lack of attention to cleanliness. Of course it will be admitted that it is not as easy to keep a Hardware store presentable as some other lines, but it is not an impossibility by any means. A store may be scrupulously clean so far as freedom from dirt is concerned, yet be far from attractive and inviting, because of the untidiness and confusion. To prevent this is fully as important as sweeping and dusting. To this end waste baskets should be placed behind the counter at convenient intervals, in which all discarded wrappings, &c., should be deposited. Another cause of untidiness is the habit of leaving articles on the counter and ledges after a sale is made, and to avoid this salesmen should be instructed to replace everything as soon as possible. However, it is sometimes impossible to do this during the busy time, but it should be attended to at the first opportunity, since it not only improves the appearance of the room, but loss by theft, &c., is avoided.

ORDER.

Where purchases are left to be called for they should be carefully wrapped and plainly marked and put in a certain part of the store. It is important that there should be a certain place for this purpose, and one clerk should be made responsible for these packages as far as possible, as much confusion and annoyance will be avoided by such a plan. While replacing the stock the tools in use around the store should be returned to their proper receptacles and the loose Nails, &c., gathered up.

COVERING COUNTERS.

At the close of business the counters, cases, racks, &c., should be covered over with gingham covers to protect them from the dust caused by sweeping and dusting. These covers will be found very convenient, as they not only lessen the labor of dusting, but preserve the goods from damage and soon pay for themselves for this reason alone.

SWEEPING.

All stores should be swept daily, and if possible the sweeping should be done in the evening in order that the dust may settle during the night.

While sweeping seems simple enough, it is a fact that it is seldom properly done. To tell the average man that he does not know how to sweep will probably arouse his indignation, but it is true, nevertheless. To some it may sound ridiculous to talk about the "science" of sweeping; nevertheless, there is a knack about it which can only be acquired by experience. It is amusing to hear a man speak about the dust in his store when you know that he does not even dampen the floor before sweeping. This scarcely sounds reasonable, but there are many who do not do this. Dampened sawdust, scattered on the floor, is better than sprinkling, since it absorbs the dust, and the floor may be swept cleaner and more satisfactorily. The old broom in the hands of the average "junior" or porter is responsible for a great deal of the dust on the shelves. The sweeping brush is so much better in every respect that its use will be continued after one trial. While the first cost is greater, they are really more economical than the brooms, as one brush will outlast several brooms.

Fig. 5.—Plane Display.

GET IT OUT OF SIGHT.

The old method of disposing of the sweeping or rubbish was to sweep it under the stove or in the corner, the easiest way to get it out of sight; but the proper way is to burn it wherever possible. If this cannot conveniently be done, it should be deposited in an iron can until it may be otherwise disposed of. It is important

that an iron can be used, since there is danger of fire from cigar stumps, &c., where wooden receptacles are used.

DUSTING.

Next comes dusting, and it is very essential that this be thoroughly done. Good feather dusters should be used, the windows raised and doors opened, and every particle of dust removed. All shelf goods should be thoroughly dusted at least twice a week, and the upper tiers taken down and thoroughly cleaned. When doing this, the older or shopworn goods should be placed on the top, where they will be the first sold. Attention to these minor details will do much to improve the appearance of the stock.

After the dusting is completed, the showcases and windows should next receive attention, as a dirty, grimy case is worse than none, because it advertises carelessness and slothfulness instead of the goods, as intended. It will usually be found necessary to clean the showcases at least once a week, and the samples should be rearranged frequently. The best method of cleaning glass is to use a cloth dampened with alcohol and dipped in whiting, ending with a polish by means of a dry chamois skin. In this way a brilliancy is imparted which is not attainable otherwise. It is a common mistake in cleaning show cases to overlook the metal corners, and the effect is as bad as unfinished work in general. These should be brightened whenever necessary, but all traces of polishing material must be removed from the glass.

In summer much annoyance will be experienced from flies, and at that season windows and cases will require careful attention to keep them clean. An effectual and inexpensive protection against these pests is common colored mosquito netting.

A SEPARATE ROOM.

Unless it be possible to have a separate room or a certain part of the storeroom for the purpose of receiving and unpacking goods, much dirt and confusion is unavoidable. Wherever possible this work should be assigned to a responsible and trustworthy person, and all goods received by him should be entered in a book especially for the purpose and the invoices checked from it. This plan does away with many errors and the unpleasantness of claims for shortages is avoided, and it is not necessary to keep the goods out of stock pending the arrival of the invoices. Under no circumstances should the cases be trucked to the various parts of the store and there opened, as such a plan not only causes a great deal of untidiness, but the goods are frequently lost or stolen.

Attention should be paid to the samples in the showcases and on the drawers, and they should not be allowed to become soiled and rusty. Whenever they show tendencies of this kind they should be replaced by new ones at once.

ENTIRELY OUT OF PLACE.

Another point worthy of mention is the gaudy and senseless placards, &c., often displayed promiscuously around the room. They seldom improve the appearance of the store and in many instances are entirely out of place. Of course there are many which are really attractive and may be displayed to advantage, provided they are not too numerous, but nine-tenths should be thrown in the fire. There are many other points worthy of consideration which cannot be treated here from lack of space, but they will readily suggest themselves to any one giving the subject the study essential to its successful application, and it is to be hoped that the interest will continue unabated and the advancement in the next few years be as satisfactory as in the past decade.

Star Hose Band.

Syracuse Specialty Mfg. Company, Syracuse, N. Y., are putting the hose band herewith illustrated upon the market.

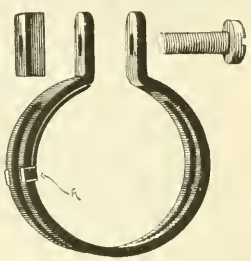

Fig. 1.—Star Hose Band.

The bands are made of rolled-strip steel, plain or coppered; well adapted, it is remarked, to this use on account of its tensile strength. The piece A, Fig. 1, is adjustable, and slides out of position when the band is being placed on the hose, obviating the necessity of spreading the band enough to destroy its form. After the band is in place on the hose the adjustable piece is slid into position, Fig. 2. This arrangement, it is stated, allows the end of the band to draw over it uniformly from both sides. The manufacturers claim that there are no sharp ends to destroy the covering of the hose or to imbed themselves, thus preventing the tightening of the screw; that there is no strain whatever on the adjustable piece; that the bands are carefully formed, uniform in shape and size; that there is no surplus metal in

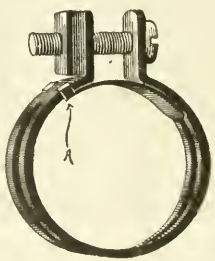

Fig. 2.—As Adjusted on Hose.

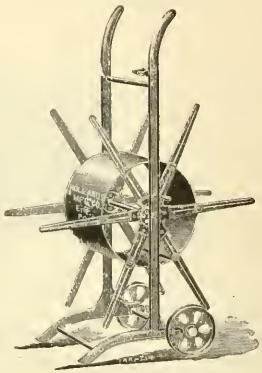
them, and that the screw would break before the band would give. The screw is adjusted with a screw driver. These bands are made for hydrant, also for steam and brewer's hose, from ⅛ inch to 2½ inches.

A colony of 2000 Waldensians, refugees from Italy, will soon remove to 12,000 acres of land purchased in North Carolina, where there is promise that they will become valuable citizens. Lumber for their dwellings is being prepared.

Metal Hose Reel.

The accompanying cut represents a ree manufactured by The Hollands Mfg. Company, Erie, Pa. The cylinder is made of heavy galvanized sheet iron, and is provided with an automatic attachment which allows it to revolve or to remain fixed, as desired. The other metal parts, with the exception of the wheels, are of malleable

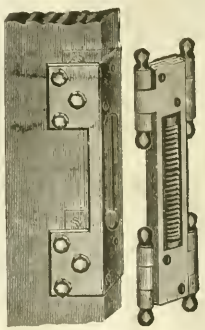


Metal Hose Reel.

iron, designed for rough usage. There is a nozzle holder attached to one of the handles, in connection with which is a spring for holding the hose firmly in place. The wheels are made larger than shown in the cut, to allow them to run freely and easily over lawns and walks. We are advised that the reels are painted and varnished in an attractive manner. Accommodation is provided by the reel for 150 feet of garden hose.

Marble Water-Closet Door Hinge Attachment.

Chicago Spring Butt Company, Union Park Place and Carroll avenue, Chicago, Ill., are offering the above attachment, as



Marble Water-Closet Door Hinge Attachment.

illustrated herewith. The attachment is made for the hinges and blanks of the Chicago spring butts, so that a door may be hung with a pair of hinges; or with a hinge and blank, when one hinge is strong enough to open the door. As the doors are of wood it requires the attachment only for the marble partitions, the hinge being attached to the wood door, as in ordinary cases. The attachments are made in sizes corresponding to their various sized spring butts, and are supplied in brass or bronze metal, and in finish to match other manufacturers' goods. The point is made that though the attachments are more suited to the Chicago spring butts, they can be used with other makes, by drilling the screw holes in them to match those in the attachment.

STOVE TRADE NOTES.

An Early Three-Flue Furnace.

More or less attention has recently been given in these columns to early cooking and heating stoves, and we are led to believe that our readers will not be less interested in some illustrations of an early three-flue furnace. We therefore present in this connection engravings of what was known as the Blanchard Furnace, the patterns for which were made in 1871 by the Boston & Maine Foundry Company of Wakefield, Mass., and passed into the possession of the Smith & Anthony Stove Company of Boston, Mass., when they bought the plant of that concern. The engravings which are here given were made direct from photographs of the old furnace and were sent us by the Smith & Anthony Stove Company as an interesting contribution to the literature of down-draft furnaces. Fig. 1 shows a partial front and side view of the furnace with the casing removed, while Fig. 2 represents a rear view.

The Smith & Anthony Stove Company have recently made a new furnace patterned after this original construction, the work being done from one of the old furnaces in the company's establishment as well as from the old patterns. The makers call special attention to the original furnace as being the first one constructed with brick-lined fire pot and having three outside vertical flues, one on either side for the descending draft and one at the back for the ascending draft. At the base the furnace has what is known as a horseshoe flue, all of these features being peculiar to several other well-known heaters now on the market. The Smith & Anthony Stove Company, referring to this old construction call attention to its priority in the field. As originally made the furnace is said to strangely resemble its modern successors. The old furnace here illustrated is said to have been a remarkable heater and there has been a steady revenue for its maker in the way of repairs.

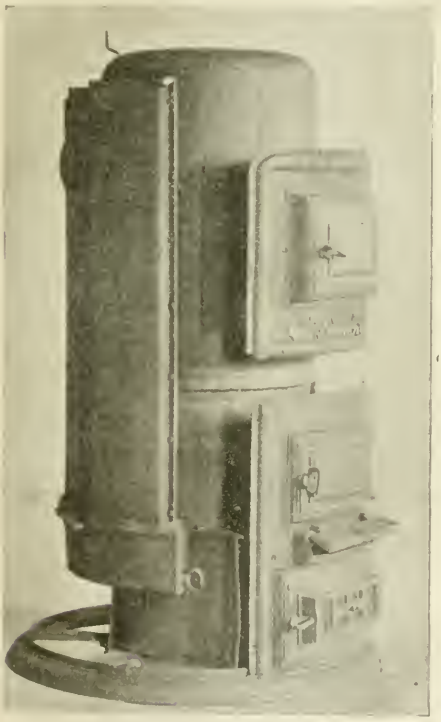


Fig. 1.—View of Side and Front.

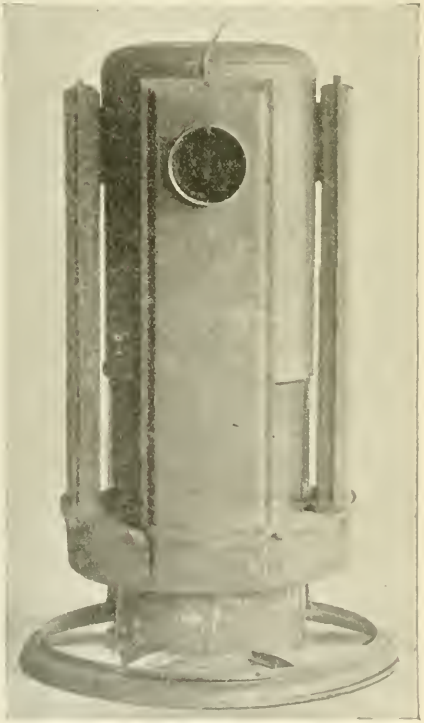

Fig. 2.—Rear View.

AN EARLY THREE-FLUE FURNACE.

AN ATTRACTIVE CATALOGUE of 32 pages has just been issued from the press of Gies & Co. by the Carton Furnace Company, Utica, N. Y. The pages are devoted to the Carton furnaces and combination hot-water and hot-air heaters, which the company manufacture in great variety. The construction and superior points of these goods are considered in a manner likely to interest the trade, while the illustrations are of such a character as to clearly show the arrangement of parts and general opperation. In connection with the illustrated matter are tables giving various dimensions of the different sizes in which the goods are made, the prices and heating capacity in cubic feet. The floor plans of an average house occupy one page of the catalogue and are presented as a guide to inexperienced furnace dealers, the company calling attention to the location of pipes, registers, sizes of the same and location and size of the cold air box. A feature of the publication is found in a number of rules for setting and piping. This is the company's forty-sixth annual catalogue and price-list, and in offering it to the trade they state that as the patterns for the Carton tubular and Carton warm-air furnaces are not yet completed the illustrated descriptions of them therefore have to be omitted from the pages. As soon as the different sizes

are ready for shipment the company will furnish price-lists and discounts on application.

The "Jewel" List of State Days for the World's Fair.

We take the following interesting article from *The Jewel Record*, issued by the Detroit Stove Works. In the names given as chairmen of the several entertainment committees, the stove trade will recognize salesmen and officials of this company.

Undoubtedly a large proportion of the leading stove merchants in every State will desire to attend the World's greatest Fair some time between May 1 and October 31. The Entertainment Committtee of the Detroit Stove Works, believing that merchants from the same State would desire to time their visit so as to meet as many State friends as possible, has arranged the list of States and the days set apart for each in the order of their admission to the Union. The following list, therefore, will be found both interesting and instructive reading for stove merchants throughout the country. The original 13 States are given in the order of their ratification of the Constitution.

In the arrangement of this list it is assumed that the fair will be open, or at least partly open, on Sundays as well as on week days, although the final action of Congress on this much-mooted question may change the programme in this particular.

Following is the list of States in the order of their admission to Statehood, the entertainment days assigned to each, and the name of the chairman of the Entertainment Committee :

Delaware day, May 1. Chairman of committee, G. M. Soverhill. Admitted, December 7, 1787.

Pennsylvania days, May 2 and 3. Chairman, James G. Insole. Admitted, December 12, 1787.

New Jersey day, May 4. Chairman, Soverhill. Admitted, December 18, 1787.

Georgia day, May 5. Chairman, H. D. Schall. Admitted, January 2, 1788.

Connecticut day, May 6. Chairman, Schall. Admitted, January 9, 1788.

Massachusetts day, May 8. Chairman, Soverhill. Admitted, February 3, 1788.

Maryland day, May 9. Chairman, Schall. Admitted, April 28, 1788.

South Carolina day, May 10. Chairman, Schall. Admitted, May 23, 1788.

New Hampshire day, May 11. Chairman, Soverhill. Admitted, June 21, 1788.

Virginia day, May 12. Chairman, Schall. Admitted, June 25, 1788.

New York days, May 13, 15. Chairman, Soverhill. Admitted, July 26, 1788.

North Carolina day, May 16. Chairman, Schall. Admitted, November 21, 1789.

Rhode Island day, May 17. Chairman, Soverhill. Admitted, May 29, 1790.

Vermont day, May 18. Chairman, Soverhill. Admitted, March 4, 1791.

Kentucky day, May 19. Chairman, Schall. Admitted, June 1, 1792.

Tennessee day, May 20. Chairman, Schall. Admitted, June 1, 1796.

Ohio days, May 22 to 27, inclusive. Committee, G. W. Patterson and J. G. Insole. Admitted, November 29, 1802.

Louisiana day, May 29. Chairman, Schall. Admitted, April 30, 1812.

Indiana days, May 30 to June 3, inclusive. Committee, George G. Garey and George Fifield. Admitted, December 11, 1816.

Mississippi day, June 4. Chairman, Schall. Admitted, December 10, 1817.

Illinois days, June 5 to 15, inclusive. Committee, J. F. Cady, Leo Goldsmith, W. J. Anderson and William Randall. Admitted, December 3, 1818.

Alabama day, June 16. Chairman, Schall. Admitted, December 14, 1819.

Maine day, June 17. Chairman, Soverhill. Admitted, March 15, 1820.

Missouri days, June 18 to 28, inclusive. Chairman, Theo. Gale. Admitted August 10, 1821.

Arkansas day, June 29. Chairman, Schall. Admitted, June 15, 1836.

Michigan days, June 30 to July 6, inclusive. Committee, J. W. Thorn, George Fifield and H. A. Furber. Admitted, January 26, 1837.

Florida day, July 7. Chairman, Schall. Admitted, March 3, 1845.

Texas days, July 8 to 12, inclusive. Chairman, H. W. Peak. Admitted, December 29, 1845.

Iowa days, July 13 to 23, inclusive. Committee, A. B. T. Moore and P. C. Jones. Admitted, December 20, 1846.

Wisconsin days, July 24 to July 31, inclusive. Committee, H. D. Bell and R. J. Millar. Admitted, May 29, 1848.

California day, August 1. Committee, J. K. Armstrong. Admitted, September 9, 1850.

Minnesota days, August 2 to 6, inclusive. Committee, C. H. Conner and R. J. Millar. Admitted, May 11, 1858.

Oregon days, July 7 to 11, inclusive. Chairman, J. K. Armstrong. Admitted, February 14, 1859.

Kansas days, July 12 to 16, inclusive. Chairman, C. F. Dietrich. Admitted, January 29, 1863.

West Virginia day, August 16. Chairman, Schall. Admitted, June 19, 1863.

Nevada day, August 18. Chairman, J. K. Armstrong. Admitted, October 21, 1864.

Nebraska days, August 19 to 23, inclusive. Chairman, Capt. M. C. Bennett. Admitted, March 1, 1867.

Colorado days, August 24 to 26, inclusive. Chairman, J. K. Armstrong. Admitted, August 1, 1876.

North Dakota days, August 28 to 31, inclusive. Chairman, R. J. Millar. Admitted, November 2, 1889.

South Dakota days, September 1 to 4, inclusive. Chairman, C. H. Conner. Admitted, November 2, 1889.

Montana days, September 5 to 8, inclusive. Chairman, R. J. Millar. Admitted, November 8, 1889.

Washington days, September 9 to 14, inclusive. Chairman, J. K. Armstrong. Admitted, November 11, 1889.

Idaho day, September 15. Chairman, J. K. Armstong. Admitted, July 3, 1890.

Wyoming day, September 16. Chairman, Armstrong. Admitted, July 11, 1890.

All States' days, September 18 to 30, inclusive. Chairman, W. M. Shaddinger, secretary Detroit Stove Works, Detroit, Mich.

All Nations' days, the entire month of October. Chairman, F. H. Tefft Barbour, vice-president Detroit Stove Works, Detroit, Mich.

JOHN GROSSIUS' SONS, 389 Main street, Cincinnati, Ohio, are distributing to the trade an oblong catalogue relating to the heating and ventilation of schoolhouses. In this publication, which is bound in colored paper covers, the company describe and illustrate Grossius' patent schoolroom ventilating heaters in such a way as to enable those contemplating the purchase of heating and ventilating apparatus to compare them with heaters of other makes adapted to meet similar requirements. The company claim that for 25 years their patent schoolroom ventilating heaters and improved warm-air furnaces have had a large sale and from the beginning have proved a practical success. The Grossius heaters are illustrated by means of numerous engravings, while elevations and floor plans of buildings show the arrangement of hot air and ventilating flues. The pamphlet is neatly gotten up, and containing information as it does with regard to putting up and using the company's heaters, will be found of interest and value to the trade in general.

WE ARE indebted to the Favorite Stove & Range Company of Piqua, Ohio, for a copy of the order of exercises of the fourth annual ball given by the I. M. U. No. 94 on April 3. The programme is of such a character that we present it herewith:

PROGRAMME.

1. Grand March..... I. M. U. No. 94
2. Waltz ..... Bill Fritz's Boots
3. Quadrille .....I'll Wrestle the Dog for $10
4. Schottische ..... A. K.—I Like Owl
5. Quadrille, Tucker, G. M.—Whoa! Stop My Horse
6. Polk.....C. B.—Does My Head Shine?
7. Waltz Quadrille .....Here Comes Papa
8. Galop, Boys, I'll Take Care of the Third Ward
9. Quadrille ...L. M.—I'm on the Fence to Dry
10. Waltz, German.....Go in, Anton
11. Quadrille.....I'll Tell You, Ain't I Right?
12. Quadrille, Doce Balenette, Stop the Horse, I'm Fell Out

30 minutes intermission.

13. Waltz.....Lou and His Little Can
14. Schottische.....Santa Claus is with Us
15. Quadrille ...Say, Boys, I'm After the Wheel
16. Polka, Success to the Favorite Stove and Range Co.
17. Waltz Quadrille, I'll Settle Down on Kitt Street
18. Quadrille, Everybody Takes His Hat Off to Me
19. Waltz, Mother, I'll Tell You Water Makes Me Sick
20. Quadrille .. .. Dan, Trim Your Lilacs
21. Waltz.....J. H.—I Feel Like a Fox
22. Quadrille, Tucker, Choice of the Third Regiment Band
23. Polka.....Joe and His Little Goat
24. Quadrille, Ma, You Wake Me Up, for Pa Is Mad at Me
25. Virginia Reel .....Home, Sweet Home

Remember 94 in their next.

On the page facing the above are blank lines for the names of the dancers, while on the fourth page or back cover is a *facsimile* of the trade-mark of the Favorite Stove & Range Company and the statement that Favorite stoves and ranges "bake better, last longer, use less fuel and are more convenient than all others."

THE FULLER & WARREN COMPANY of Troy, N. Y., have recently discovered who has been systematically robbing them for several months past. The chief conspirator is said to be the foreman of the molding shops, and, according to our Albany correspondent, he has made a confession, implicating nine men employed under him. It appears that the plan pursued by the foreman and his accomplices was to credit the men each day with more work than they really performed and on pay day after cashing their slips the men would meet and divide the amount received in excess of that to which they were justly entitled, the foremen, of course, receiving the lion's share. It is said that the foreman had one of the most lucrative positions in the foundry, making legitimately as much as $50 a week. By his scheme, however, he more than doubled the amount. His mode of living is said to have aroused the suspicion of his employers and an investigation followed. The foreman was arrested and at last advices had been admitted to bail in the sum of $1500.

THE WESTERN STOVE MFG. COMPANY, 506 North Main street, St. Louis, Mo., favor us with a four-page circular relative to some of their leading specialties. Among these may be mentioned the Model Bakewell, a four-hole cook, intended for using coal as a fuel and made in a great variety of styles and sizes ; the Bonny Bake-well, a six-hole range, intended for using wood only ; the Midland, a neat four-hole cook for coal or wood, and the Cherry and Eureka, four-hole wood cooks. The circular presents more or less letterpress, while the illustrations are of a character to clearly show the external features.

An Old Heating Stove.

The engraving of the ancient looking heating stove presented herewith is made from a photograph sent us by Stone, Brewster & Co. of Windsor, Vt. They state that the stove was recently brought to them as old iron, and as they are interested in knowing something of the probable age of the construction, they send the picture to *The Metal Worker* in order that it may be presented to our readers. The only name on the casting appears on the panel just above the front doors and reads as follows : "John Morrison, Troy, N. Y., No. 4." According to our knowledge on the subject, Mr. Morrison was in business somewhere about 1840, which would indicate very closely the age of the stove here shown. The picture represents a type very common about 50 years ago, and was turned out by the leading stove makers of Albany and Troy. It is of especial interest at this time as an illustration of the tendency to revert to old principles in artistic casting. The decoration is rich and effective, and it will be observed that nearly the whole of the exposed surface is covered with ornamentation. The columns at the side and the drum or radiator at the top afford a considerable amount of radiating surface, while at the same time adding to the artistic appearance of the stove. The wood is placed in the fire box through the door at the end of the stove, and the products of combustion pass upward, radiating their heat, and then escaping to the chimney through the radiator or chamber supported by the circular columns. If any of our readers can furnish additional information regarding this type of heating stove we shall be glad to have them do so.

Old Heating Stove Made by John Morrison, Troy, N. Y.

ODD PLATES.

The Howard Furnace Company, 254 Water street, New York, and Syracuse, refer to many generous testimonials from the trade in relation to their line of goods. They have a new catalogue in course of preparation which they hope to issue the coming May or June. This will contain a new line of single radiator furnaces, of which four sizes—Nos. 32, 36, 40 and 44—are now ready, and two more—Nos. 48 and 56—they expect to have ready by June 1. They have also ready six sizes of combination furnaces for hot water and hot air.

We are indebted to Fletcher, Russell & Co., Limited, Warrington, England, for a copy of their catalogue of gas-burning appliances bearing date of March, 1893. It is a volume of 125 pages, and its make-up is similar to the publication reviewed in these columns a short time since. Numerous illustrations are given of heating and cooking stoves adapted to meet the requirements of the English trade, while ample descriptive matter calls attention to the leading features. A selection of testimonials also finds place in the catalogue, showing the favor with which the goods are received by those who have practically demonstrated their merits.

Treasurer Roberts of the Auburn Stove Foundry Company, Auburn, Me., states that the sales of the company's goods are increasing from month to month and are much larger thus far the present year than for the corresponding period a year ago. The iron that is being melted produces fine, smooth castings, and the stoves and ranges are meeting with great favor.

The Syracuse Stove Works, Syracuse, N. Y., are directing attention to their Model Welcome six-hole range as a "new departure in stove construction." It is fitted with sheet flue, large top surface measuring 30 x 48 inches; ash pit 6 inches deep and 17 inches wide; fire box intended for burning coal, 9 x 18 inches in size, and 10 x 24 inches for using wood as a fuel. The ornamentation is of a pleasing character, and the company are confident that the Model Welcome is destined to be a great seller.

James Boyle & Co , Salem, Ohio, favor us with a calendar for the month of April. In the general make-up it corresponds to those of the earlier months of the year sent out by this firm, being illustrated with an engraving of the Family Keystone four-hole cook stove and printed in colors. Around the panel inclosing the calendar proper for the month is the statement that "next month will show cut of Perfect Oak, latest and finest in the market. Don't buy your Oaks until you see it." The card bears the imprint of Frank H. Peterson & Co., Minneapolis, Minn., as agents for the Northwest.

President Nathan B. Perry, of the Perry Stove Company, Albany, N. Y., who has been away on a ten-days' vacation, has returned to the management of this progressive concern.

Stumpf & Thiele of Indianapolis, Ind., are meeting with such a demand for their furnaces that they operate their works day and night in order to fill orders. Their output is larger than ever before in their history, and the prospects are for a continuance of the present satisfactory conditions.

The Co operative Stove Company of Buffalo, N. Y., deny the statement that they are discriminating against union men. The manager of the company says the concern employ union labor, and applicants for work are never asked whether they are non-union men or not.

Troy Nickel Works, Troy, N. Y., have appointed Francis Frost & Co., Toronto, Ont., as Canadian agents for the sale of their Alaska Stove Trimmings.

Eugene Munsell & Co , 218 Water street, New York, are distributing circulars, printed in colors, relating to their Manhattan gas stoves, made in a great variety of styles and sizes, and also to Graves' permanent gas-burner attachment. The latter device, our readers will remember, was illustrated in these columns not many weeks ago. The circulars are liberally illustrated and carry sufficient descriptive letterpress to enable the dealer to readily comprehend the merits of the device referred to.

The Ringen Stove Company, St. Louis, Mo., are adding another story to their manufactory, which will, when complete, make it a four story building 75 x 200 feet. The entire structure will be devoted to the manufacture of the Quick Meal gasoline and gas stoves. Last year

their increased business compelled them to build an additional story to their foundry, which is 60 x 100 feet, so that the improvements they are at present making indicate that their business is steadily growing. They have two large warehouses, which they use for the storage of goods, and it is more than probable that these will shortly be supplemented by an additional warehouse.

H. SANDMEYER & Co., 215 South Adams street, Peoria, Ill., have just issued from the press a very neat catalogue of 64 pages, bound in colored paper covers. The first portion of the work is devoted to the subject of house heating and ventilating and to illustrations and descriptions of the line of furnaces made by the company. These include the Imperial, the Victor, the New Style Pleasant Home, the Prince Royal and the Royal, the latter being a furnace intended for burning wood only. Tables giving dimensions of the various sizes of the different furnaces made, together with price-lists and capacities, are features of the work. The latter portion of the catalogue is devoted to illustrations of sheet-metal store fronts, crestings, finials, skylights, window caps, gutters, &c., manufactured by the company. One page is devoted to Dickson's Dry Closet System for schoolhouses.

THE MARCH number of the *Gasoline Stove Bulletin*, issued in the interests of George M. Clark & Co. of Chicago, Ill., is full of matter pertaining to vapor stoves which is likely to interest dealers everywhere. On the editorial page the company state that March found them doing the largest business in their experience, and in explanation of this they state the reason is simply because they have a good line of gasoline stoves of all kinds to suit all people. The Jewel Process range is given a conspicuous place in this number of the *Bulletin*, the shipments for one week reaching a total of 2600 stoves. The last page is devoted to a letter in *fac simile* from the company's largest agent. It is short, but tells of two classes—the dealer and the wholesaler.

THE EXCELSIOR MFG. COMPANY, St. Louis, Mo., who recently placed on the market a line of wrought-steel ranges, known as the Monarch, report a heavy demand for these goods, and advise us they are in receipt of some gratifying orders for them. They are substantially made, and are sold at a reasonably low price.

W. H. PECKHAM, manager of the Chicago branch of the Sill Stove Works, is having his sample room overhauled and redecorated to present an inviting appearance to the crowd of visitors expected this summer.

THE MICHIGAN STOVE COMPANY of Detroit, Chicago, Buffalo and New York announce that they are bringing out an entirely new line of cast cooking goods in both ranges and stoves, to cover requirements for wood or any kind of coal. All styles and sizes will be found in this line. It is almost unnecessary to add that the Michigan Stove Company's reputation insures the appearance of something very fine this World's Fair year. Their steel ranges are having an excellent sale, winning their way largely through their own merits.

WE HAVE RECEIVED a very dainty invitation from the Peninsular Stove Company to the opening of their new salesrooms, 79 and 81 Wabash avenue, Chicago, on the 7th inst. The rooms were open from 7 to 10 o'clock in the evening, cards having been issued to the fortunate ones who were favored with invitations.

Grave questions relating to the efficiency of quarantine regulations are raised by the landing at Halifax of emigrants bound to the United States.

Municipal Laws as to Rain-Water Conductors.

The following digest of municipal building laws in regard to rain-water conductors, compiled by Henry A Phillips, is printed in the *American Architect:*

Boston.—1. Buildings over 45 feet high shall have suitable water tight metallic leaders, and all buildings shall have leaders sufficient to carry all water to street, gutter, or sewer, and in such manner as not to flow upon sidewalk, or to cause dampness in any wall, yard or area.

2. Rain-water leaders, when connected with soil or drain pipe, shall be properly trapped.

Baltimore.—1. Inspector is directed to compel owner or his agent to put proper metallic spouting and gutters on buildings, and keep same in repair, so that gutters shall not leak nor overflow to pavement, and carry water from roof to ground, sewer or gutter, protecting walls and foundations.

2. Awnings not extending over curb-stone shall be provided with gutters and down spouts to carry water to street gutters.

Brooklyn.—1. Wooden gutters of stone or brick buildings shall be lined or covered on upper surface with copper or other fire proof material to be approved by commissioner.

Chicago.—1. Buildings shall be kept provided with proper metallic leaders for conducting water from roof to ground, sewer or street gutter in such manner as shall protect walls and foundations from damage.

2. In no case shall water be allowed to flow upon sidewalk.

3. But shall be conducted by drain pipe to street gutter or sewer.

4. Rain-water leaders must never be used as soil, waste or vent pipes, nor shall any soil, waste or vent pipe be used as a leader.

5. Water leader within house must be of cast iron with leaded joints, or of copper with soldered joints When outside house and connected with house drain, it must, if of sheet metal with slip joints, be trapped beneath ground or just inside wall, the trap being arranged to prevent freezing. When leader opens near window or light shaft, it must be properly trapped at its base. The joint between a cast-iron leader and roof must be gas and water tight by means of brass ferrule and lead or proper pipe properly connected.

Cincinnati —1. Buildings shall be provided with proper fall pipes connected with sewer, or to catch basin connected with sewer when building abuts on street or alley containing public sewer; otherwise water shall be carried to street gutter in manner approved by inspector.

2. Rain-water leaders, when connected with soil or drain pipe, shall be properly trapped.

Cleveland.—Same as above (1) for Cincinnati.

Denver.—1. Rain water shall be so conveyed from roof as not to flow upon adjoining property, nor against any wall so as to endanger it or cause dampness therefrom, and all water conducted from building to street gutter or sewer.

2 In no case shall water be allowed to flow upon the sidewalk.

Detroit.—All gutters shall be of metal.

District of Columbia.—1. Buildings shall be kept provided with metallic down spouts and eave and cornice gutters for conducting water without damage to walls or foundations, so as not to drain upon or damage adjoining property, and by drain pipe to sewer, or to gutter under sidewalk where no sewer exists.

2. In no case shall water be allowed to flow upon sidewalk.

Kansas City.—1. Same as above (5) for Chicago, and brick buildings shall be kept provided with suitable water-tight metallic leaders, and all other buildings with water-tight metallic or wooden leaders conducting water from roof to ground, and thence to street gutter or sewer.

2. In no case shall water be allowed to flow upon the sidewalk.

3 Buildings shall be provided with proper fall pipes connected with sewer, or to catch basin connecting with sewer, when building abuts on street or alley containing public sewer; otherwise water shall be carried to street gutter in manner approved by inspector; not drip on ground or cause dampness in wall, yard or area.

Minneapolis.—1. Buildings fronting on street shall be kept provided with proper leaders for conducting water from roof to ground, sewer, street gutter or dry well in such manner as shall protect walls and foundations from damage. No leader shall be constructed except in accordance to law.

2. Rain-water leaders running down outside of building shall have trap or back-pressure valve before entering sewer, drain or soil pipe.

3. Rain-water leader within building shall be extra heavy cast-iron soil pipe, or standard wrought iron pipe tarred inside and outside.

4. Connection of rain-water pipe with soil and drain pipes shall be on lower side of highest fixture.

5. A soil or vent pipe above highest fixture shall not be used as rain water pipe.

6 Rain-water pipe running from low roof or low eaves shall have trap or back-pressure valve before entering drain or sewer pipe.

Nashville —Water spouts emptying contents on public sidewalk shall be connected with gutter by drain laid beneath surface of sidewalk.

New Orleans —1. Gutters on buildings where fire-proof roofs are required shall be made of non-combustible material, and firmly secured to building by irons.

2. Balcony projecting over any part of banquette shall be provided with metal gutter attached to outer edge and leading into metallic down pipe, leading across banquette into street gutter. But if balcony is entirely roofed, then such gutter shall be attached to roof.

3. Gutters shall be kept in such repair that they do not leak or drip on sidewalk.

4. Gutters across banquette shall be covered and approved by City Engineer.

New York.—1. Buildings shall be kept provided with proper metallic leaders for conducting water from roof to ground, sewer or street gutter in such a manner as shall protect walls and foundations from damage.

2. In no case shall water be allowed to flow upon sidewalk if there is sewer in street. Pipe shall be below surface of sidewalk.

Omaha.—1. Same as Chicago (5).

2. Same as above for New York (1 and 2).

Providence.—1. Buildings fronting on street shall be provided with proper leaders conducting water from the roof to ground, sewer, street gutter or dry well in such manner as to protect walls and foundations from damage. (*g.*)

2. *Tenement and Lodging houses,* water shall not drip from roof so as to cause dampness in walls, yard or area.

St. Louis —1. All buildings shall be provided with proper metallic leaders conducting water from roof to ground, river or street gutter in such manner as to protect walls and foundations from damage.

3 In no case shall water be allowed to flow upon the sidewalk, but shall be conducted by drain pipe to street gutter or sewer.

San Francisco.—Gutters on brick buildings reconstructed shall be made of fireproof material.

Gray's Telautograph.

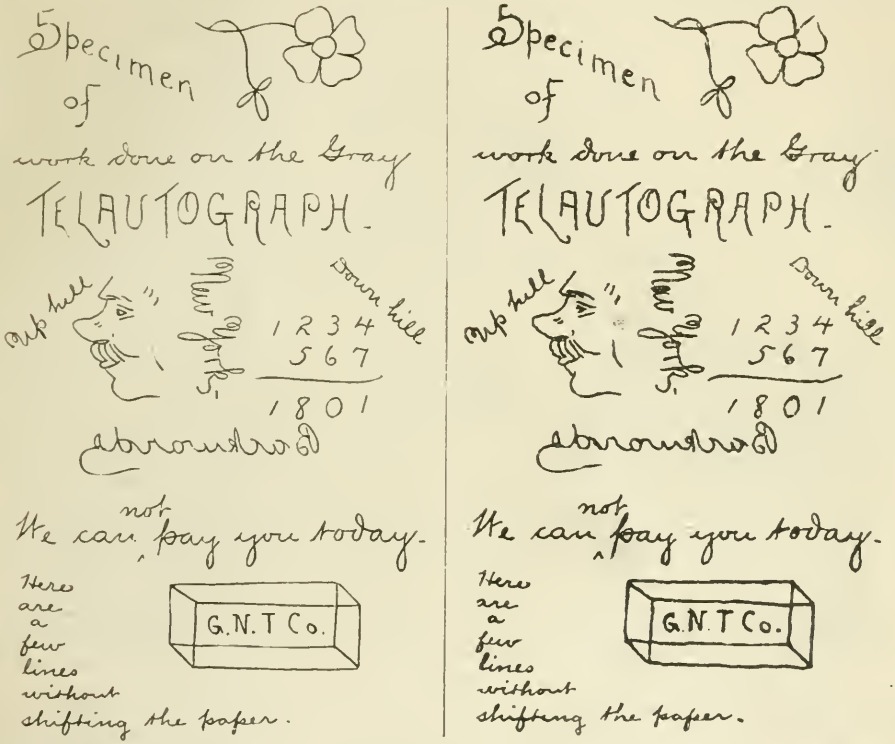
If expert electricians are not wofully mistaken, another very important aid to the facilitation of business has been perfected. Professor Elisha Gray, of Highland Park, Ill., after six years of constant experiments, last week exhibited his apparatus for transmitting by wire a *fac-simile* of anything written or drawn, the apparatus being of such a simple character that a skilled operator is not necessary. It is claimed that every obstacle which has hitherto defeated the attainment of this long-sought process has been surmounted, and that the apparatus is ready for introduction into practical every-day use. It is styled the telautograph. A transmitter and a receiver are used, each somewhat smaller than a of letters, words, figures, signs or sketches. Apparently, the only limit in reproduction is that of stenographic characters, as the machine makes but little distinction between heavy and light lines.

The cut which accompanies this sketch, reproduced from the *Electrical World*, represents a telautographic message as written and received through an artificial distance representing one mile. This shows clearly the fidelity of the reproduction. Printing, script, and sketches transcribed horizontally, uphill, downhill and backwards are all with equal faithfulness copied by the receiving pen. The illustration shows the exact size of the transcribing plate.

Assuming that the telautograph is now in as good condition for practical use as which will be appreciated by those who occupy their offices irregularly.

The *fac-simile* of the original writing of a message which is provided by the telautograph will avoid many disputes and mistakes arising in the transmission of communications by our present system. Even the identity of the writer or sender is thus preserved and can be traced by those familiar with his penmanship. Contracts in much more satisfactory form can be made in this way than by telegraphic message or telephone, and it may not be necessary to add, as now "Please confirm by mail."

The size of Australis, justly says an exchange, is not generally appreciated. The seven colonies between them occupy a territory greater than that of the United



As Written. *As Received.*

SPECIMEN OF WORK DONE ON THE GRAY TELAUTOGRAPH.

type-writing machine. The transmitter and receiver stand side by side. In sending a message an ordinary lead pencil is used, near the point of which two silk cords are fastened at right angles to each other. These cords connect with the instrument, and, following the motion of the pencil, regulate the current impulses which control the receiving pen at a distant station. Ordinary paper five inches wide, arranged on a roll attached to the machine, is used by the writer. The receiving pen is a capillary glass tube placed at the junction of two aluminum arms. This glass pen is supplied with ink, which flows from a reservoir through a small rubber tube placed in one of the arms. The electrical impulses coming over the wire move the pen of the receiver simultaneously with the movements of the pencil in the hand of the sender. As the pen passes over the paper, an ink tracing is left, which is always a *fac-simile* of the sender's motion, whether in the formation was the telephone when first brought out, a magnificent range of possibilities is presented. Private wires for the transmission of messages can be furnished business offices as easily as telephonic communication is now established. A business man can receive and transmit his own messages without the intervention of a messenger boy and also without having them pass under the scrutiny of two or more telegraph operators. Further, not only does he secure secrecy, but he also obtains a record in black and white of his telegraphic correspondence, including exact reproductions of the communications sent by the party at the other end of the wire. The telegraph and telephone may not be superseded, as they have their uses; but the telautograph steps in to occupy a field which neither of them can cover. As the receiver works without any attention, persons having telautograph connections can be furnished with dispatches or messages at any time, day or night, States, excluding Alaska. New South Wales alone is as large as the 13 original States. Tasmania, the Rhode Island of Australia, is as large as that State, with New Jersey, New Hampshire and Massachusetts added; Victoria, the smallest colony of the continent, is equal in size to Great Britain. Queensland surpasses the united areas of Austria, France and Germany. South Australia, one-third greater than Queensland, is nearly as large as Western Australia, which of itself has nearly four times the extent of Texas, while the two colonies together are larger than the whole of Europe without Russia. The total population is about 4,000,000.

Honduras is engaged in slaughtering her own citizens as a means of promoting the general welfare. In Southern Brazil the same tactics are adopted. The greater the victories achieved the greater the disaster.

Estimate Blank for Furnace Work.

The Excelsior Furnace Company, Chicago, Ill., have got up for their customers and the trade in general a very complete form of estimate blank, consisting of four pages 14 x 8½ inches in size. The front page is reproduced below. The inner pages contain a very complete list of registers and furnace fittings, smoke pipes, air pipes, &c. The names are given, also the sizes, as well as the list price, while two blank columns are left for inserting the cost, so that a complete and accurate estimate can be made. On the back of the blank or fourth sheet are lines for indorsing the name of the owner, architect, and the date the contract was submitted, besides half of blank page for memorandum of runs of pipe and special instructions. We print above first page of blank.

Eaves Droppings.

The spring poet is sure to come with the season, and even *The Metal Worker* can't escape him. The following harmless ode in praise of the tin roof is sent to us by one who should know better.

If you want to get a roof
That is surely waterproof,
Tin's the thing you ought to buy;
It will keep you nice and dry.

It doesn't freeze and lose a slate,
To make you cuss when too late;
Or on the house to put a strain
To hold its weight—that is plain.

You can't see the stars in bed
With a tin roof overhead;
But on shingles far less plain
Sounds the music of the rain.

Stand all the roofs in a line,
Nary one will tin outshine;
Tin's the roof that does the trade,
And throws the others in the shade.

Burning Gas in Stoves.

Following a discussion of a paper on a special form of gas heater, read at the ninth annual meeting of the Ohio Gaslight Association, some interesting statements were made respecting the use of gas for heating purposes. Our readers will recall some discussion in recent issues of *The Metal Worker* on dampness arising from burning gas in a room with no flue connection. In the discussion referred to it was stated that the burning of one pound of natural gas makes two pounds of water. One of the speakers, referring to the effect of the combustion on the air of the room, said:

My own experience in heating rooms with gas where there is no flue connection is that the presence of carbonic acid is not perceptible, or not disagreeable, but the presence of steam is a worse difficulty; and next to that, and more serious, is the fact that the oxygen is burned out of the air, leaving the nitrogen. The point I don't understand is how a room can be heated for 24 hours at a time with a stove burning 10 or 15 feet of gas per hour, destroying the oxygen in the air all the time and leaving the nitrogen; and yet I know by actual experience in my own house and the houses of a great many of my friends that a room can be heated in that way and kept perfectly pleasant. It seems to me that unless there is some means by which the nitrogen gets out doors and the oxygen comes in, that the atmosphere inside will become so charged with nitrogen that it will not support life.

The Carpenter Calorimeters.

Schaffer & Budenberg of Brooklyn, N. Y., have arranged with Professor Carpenter of Cornell University for the sole manufacture and sale of calorimeters invented and patented by him. The throttling calorimeter proper is made of brass, nickel-plated, and consists of a small vessel to which steam is supplied through a tapering or converging orifice, and which contains in its center a very deep cup, into which a thermometer can be inserted for obtaining the temperature of the steam in the calorimeter; the calorimeter is furnished with a cock, to which a manometer can be attached for measuring the pressure in the interior. The exhaust steam is discharged from the lower part of the calorimeter, and need not be condensed; it may be conducted away in a hose or pipe, or permitted to escape into the air, as convenient.

The principle on which the calorimeter operates is as follows: Some of the heat contained in high-pressure steam is liberated when the pressure is lowered, and that heat is utilized in evaporating any water the steam may contain and in raising the temperature of the steam above that due to its pressure. Thus the total heat in 1 pound of steam at 80 pounds absolute pressure is 1177 B. T. U., and that in 1 pound at 20 pounds absolute pressure is 1151 B. T. U. If, now, steam were allowed to expand, without doing work on any body except itself, from 80 to 20 pounds pressure, 26 B. T. U. would be liberated for each pound of steam. Since at 20 pounds pressure 954 B. T. U. are required to evaporate 1 pound of water, we should have additional heat sufficient to evaporate 26 ÷ 954, or 0.027 pounds. Now, if the original steam contained less than 2.7 per cent. of moisture, a thermometer placed in the steam would show a temperature higher than that due to a pressure of 20 pounds, which is 228° F. In such a case it would be possible to compute the percentage of moisture in the steam; but if the steam contained more than the above moisture, the heat would not be sufficient to evaporate it, the reading of the thermometer would be equal to that of the boiling point for the given temperature, and no computation of the moisture in the steam would be possible. That is, a throttling calorimeter cannot be used if the steam contains much over 2.5 per cent. of moisture, but it is very convenient and accurate when it can be operated.

The separating calorimeter consists of a vessel about 12 x 3 inches, constructed so that steam in passing will be completely and perfectly separated from any moisture that it contains. The moisture is precipitated in an interior chamber, which is connected to a water gauge glass and scale, so that the amount of water can be seen and its volume of weight read off on a scale. The dry steam passes into an external chamber, which surrounds the inner chamber and forms a steam jacket, which prevents the loss of heat by radiation from the inner chamber. The dry steam and such water as may be formed in it by condensation after leaving the calorimeter is discharged at the bottom of the outer chamber through a small orifice. This steam is caught in a condensing vessel and its weight determined from the increase in volume of the original water in the condensing vessel. The scale on the calorimeter gives the weight of moisture, that on the condensing vessel the weight of dry steam.

The per cent. of moisture in the whole weight is then evidently the quotient obtained by dividing the weight of steam, as shown by the calorimeter scale, by the sum of that shown by the scales on the calorimeter and the condensing vessel. The quality of the steam is 1 minus this number.

TRADE REPORT.

The Iron Market.

In Eastern markets the commencement of the fourth month in the year does not bring with it any new or encouraging features. The volume of business is large, and prices are steady, but they are so low that manufacturers insist that they are working on so small a margin that it precludes the idea of doing more than getting out whole. Further weakness, therefore, is something they dread to meet, and yet it is not entirely certain that this can be avoided. As already stated, there is no reason to complain of business being dull; the point is, that it is unprofitable, and it is not clear how it can be made otherwise, unless there is some very decided change in the conditions, of which there is no immediate probability. Supply and demand are very evenly balanced; the weak point is, that the facilities for production are growing all the time, so that, heavy as the demand is, and heavy as it may be, the impression prevails that it can be easily met, hence there is no inducement for speculative buying. Many large producers are also of opinion that there is no good reason for refusing any business that can be had at about the figures now ruling, which appears to be confirmed by the ease with which orders are placed for material of almost any description. Apart from the matter of prices there is no room for complaint, and it may be that even in that respect the situation is not as bad as it is made out to be. This article simply aims to voice what the trade have to say, which, in regard to prices, is singularly in accord.

The prospective early opening of navigation is influencing prices at Chicago on articles which can be shipped from Eastern lake ports at lower than all rail rates. The volume of business handled in this way is increased every year with the better services offered by the growing fleet of steam carriers to Lake Michigan ports, as well as to points reached through towns at the head of Lake Superior.

Pig Iron.—The New York market is very quiet, although it is pointed out as a feature that quick delivery is usually demanded by consumers. Both Alabama and Virginia Irons are occasionally pressed for sale. We quote Northern brands at $14 50 @ $15.25 for No. 1; $13 75 @ $14.50 for No. 2, tidewater. Southern Iron, same delivery, $14.25 @ $14 50 for No. 1; $13 @ $13.75 for No. 2 and No. 1 Soft.

In the Philadelphia market the demand for Pig Iron is much of the same character as noted for several weeks past, fairly active for standard brands, a little slow for other descriptions. There is no particular pressure to realize, however, so that in ordinary cases sales are at unchanged prices. At a reduction of a few cents per ton, sales could easily be increased, while a few cents advance just as effectually checks the demand, so that the market may be said to be about on an even keel. Consumption is nearly up to its maximum, and while there may be some further increase during the next 60 days, the chances are equally strong that the supply will keep pace, particularly if there is any stiffening in prices. Taking everything into consideration, therefore, there does not appear to be much chance for higher prices, while at the figures now ruling it seems equally improbable that there can be any appreciable decline, and, as a matter of fact, the trade are so much in accord on this point that it is impossible to get up anything like a scare. Buyers feel that they can get all the Iron they are likely to need at current prices, while sellers are equally sure that concessions are uncalled for, unless for an off grade, for spot cash or for some reason peculiar to that particular transaction. For the present, therefore, sales are about on a par with the supply, and prices are steadily held as follows for Philadelphia and equivalent deliveries, with 25¢ @ 50¢ less on Southern brands at Harrisburg and intermediately to Baltimore:

American Scotch, No. 1X.....	$16.00 @ $16 50
American Scotch, No. 2X.....	15 00 @ 15.50

Reports from Chicago indicate that the situation is practically the same as that reported last week. A fair amount of trade has been done in local Coke Iron, the inquiry still being good from a considerable number of consumers. Prices on this class of Iron are quite firm, and transactions are notably increasing at slightly advanced rates. March deliveries from the furnaces here were unusually heavy, running easily 25 % above those of the corresponding month last year. Southern Iron has been rather quiet. Hardly anything has been done to establish prices, but from offers which have been made the condition of the Southern furnaces does not seem to have improved, although the leading companies refuse to meet extremely low prices current within the past two weeks. The Lake Superior Charcoal producers are feeling rather sanguine over their prospects. A better demand is reported in other markets, and not a few furnace companies have already sold their entire product for several months. A good inquiry is reported here, but consumers are not disposed to pay full prices. Offers are made of 25¢ @ 50¢ below quotations, which sellers are refusing to accept. Quotations are as follows, cash, f.o.b. Chicago:

Lake Superior Charcoal	$16.50 @ $17.00
Local Coke Foundry, No. 1.....	13.75 @ 14.25
Local Coke Foundry, No. 2.....	13.00 @ 13.25
Local Coke Foundry, No. 3.....	12.75 @ 13.00

From Cincinnati we learn that there is a fair volume of business passing in Pig Iron, but there have been no extended purchases made during the week. Buyers are urgent for prompt delivery of current purchases and for all Iron due on previous contracts, but the tone of the market has not improved and prices are as low as ever—in fact, we hear of one sale of No. 2 Foundry made direct by the furnace to consumer as low as $8.75, f.o.b., Birmingham, and for delivery running through this year. This, of course, is an exceptional transaction on which no commission was paid, but there is no doubt that sales have been made at $9, f.o.b., Birmingham, although 25¢ more is generally obtained. While there is liberal melting of Iron by the foundries in nearly all lines of business, yet there is such an abundance of Southern Iron for sale that buyers do not seem disposed to anticipate their wants more than is absolutely necessary. Only the larger and strong Iron companies contend firmly for full prices, and other producers are so numerous as to make it easy to buy at the low rates current. Many hope that stocks will show such a material reduction during the month of March as to favorably affect the trade, but this hope is by no means confident and there are few, if any, furnaces which would not take orders to a liberal extent for immediate or short forward delivery at the current prices. A considerable part of the business here is for Eastern destination, and yet the quantity of Pig Iron passing into consumption in this district is of liberal proportions. Quotations are as follows:

Foundry.

Southern Coke, No. 1.....	$13 25 @ $13.50
Southern Coke, No. 2.....	11.75 @ 12.00
Southern Coke, No. 3.....	11 00 @ 11.25
Ohio Soft Stone Coal, No. 1.....	16.00 @ 16.25
Ohio Soft Stone Coal, No. 2.....	15.00 @ 15.25
Mahoning and Shenango Valley...	14.75 @ 15.00
Hanging Rock Charcoal, No. 1....	19.00 @ 19.25
Hanging Rock Charcoal, No. 2....	18.00 @ 18.50
Tennessee and Alabama Charcoal, No. 1.....	15.50 @ 15.75
Tennessee and Alabama Charcoal, No. 2.....	14.50 @ 14.75

Metal Market.

Copper.—The conditions are practically the same as outlined in last week's review of the market. In any event, the turn from the first to the second quarter of the year has witnessed no change in the attitude of buyers, and even with seven or eight months' restriction upon production there is still more than enough Copper to go around. For that matter, the surplus is

sufficient to have more or less depressing effect upon values, and has brought the market into a condition of feverishness, the end of which is extremely problematical. At present there are sellers of Lake Superior Ingot for prompt delivery at 11¼¢, regular terms, and Exchange contracts running as far ss August have been offered at the same price, without attracting buying orders. Cakes and Wire Bars for prompt delivery brought some premium over that price, but the demand for those is rather disappointing and orders for round lots could probably be placed at prices very close to current quotations for Ingot. Casting Copper is also easier. In fact, 10¾¢ has become a common selling price for round lots, while transactions involving only moderate quantities were effected at 10.70¢, if, indeed, not at a shade less.

The monthly report of the Bureau of Statistics affords the following comparison of exports of copper from the United States:

	February, 1893. Tons.	February, 1892. Tons.	Eight months ending February 28, 1893. Tons.	Eight months ending February 28, 1892. Tons.

Total	17,955,875.	46,205,567

Pig Tin.—The enevitable working of the law of supply and demand has dispelled the visions of the "bull" interest and turned prospective profits into realistic losses. The McKinley duty "boom," has disappointed its fathers, chiefly because of the fact that sellers on one end of the line have put out more Tin than the buyers on the other end could conveniently take care of. The accumulation has become burdensome to an extreme and the odds are that the surplus will be heavier at the end of the present month. There is more than a bare chance also that "invisible" supplies will have some weight during the interval. A reflection of what the "bull" interest have to contend against may be discovered in the statistics presented below. Since our last report, the net cash price for Straits Tin has dropped about 40¢ ℔ 100 lb. Numerous "short" sales were covered at the decline, and advantage was taken of "seller's right to double" contracts in a manner anything but pleasant to operators who bought on that form of contract. Trade and consumptive demand has been only fair and doubtless checked to some extent by the depressed condition of the market.

Below we give the total statistics for Europe and the United States, as compiled by the New York Metal Exchange, showing: Total visible supply April 1, 1893, 17,855 tons; against total visible supply March 1, 1893, 15,959 tons: against total visible supply April 1, 1892, 13,039 tons.

Shipments During March and February.

	Mar. Tons.	Feb. Tons.

Afloat, Holland	600	1,020
Afloat, U. S., excl. Pacific ports,	3,285	2,820
Total afloat at the close of month	8,970	7,525

Pig Lead.—During the greater portion of the week under review prices dragged on the level of 4 05¢ for Common Domestic and 4.10¢ for corroding quality In the interval somewhat extensive purchases were made by large consumers that not only cut rather deeply into spot stocks, but materially curtailed the offering for early shipment from the West. The outcome was a hardening of prices all along the line and very firm tone to the market at the close. At this writing 4.10¢ would appear to be bottom price for common Western. Some single carload lots have been sold at that during the past few days.

Spelter.—Transactions in this market have been on a smaller scale and the demand shows hardly the degree of life that was displayed a week ago. Prospects for successful outcome of the proposed combination of producers seem somewhat dubious and that fact along with continued heavy output may account in a good measure for the more conservative tendency of buyers. However, prices are still held at 4.30¢, delivered, for carload or larger lots of prime Western brands.

Antimony.—The demand has been of merely routine character and prices are barely steady at 10¢ @ 10¼¢ for Hallett's, 10¼¢ @ 10½¢ for LX and 10½¢ @ 10¾¢ for Cookson's.

Tin Plate.—Deliveries from late heavy arrivals supply trade requirements to a great extent. The probabilities are that arrivals will continue heavy for some time, as large amounts of Plates have been shipped from abroad in order to avoid probable higher rates of ocean freight. Purchases for both prompt and future deliveries are, therefore, moderate, and the business passing is practically at old prices. The past week has brought somewhat of an increase in orders for Tin Plates from consumers, owing largely to the more favorable weather for outside work. Prices remain unchanged.

Coal.

The Coal market is dull and slumpy all around. Just now the Bituminous trade is exercised on account of the low contract of the Long Island Railroad Company which has been closed with R. B. Wigton & Co., at less than $2 70 ℔ ton for 80,000 tons, delivered at Hunter's Point. It is known that the railroads were expecting to get 15¢ more ℔ ton for transportation, but with such prices as that just quoted operators do not see how this can be done. Bituminous Coal is in good supply, so that some of the Clearfield mines are known to have shut down, as supposed from the effects of severe competition.

In the Anthracite Trade the resignation of Mr. McLeod from the Reading is startling news, as nothing of the kind was looked for. The trade reasons that he was simply crowded out, the funds at command proving insufficient to carry through the immense projects of the combine. Of course the combine no longer exists, nor has it been extant since the withdrawal of the Jersey Central. The Reading and Lehigh are alone, under a single management. "Company prices" now rule, and these several companies fall back as they were, renewing former tactics, which meant little more than meeting once a month or so, agreeing to maintain a schedule, and each concern afterward doing as it thought best. Prices remain unchanged, McLeod's retirement being too recent for effects to be seen or even conjectured. Talk of an advance in June or any other time this season is absurd, unless it is intended simply to be made on paper. The April output is calculated at 3,000,000 tons. The Reading Railroad has reduced the rate of tolls on Anthracite from the Schuylkill region 5¢ ℔ ton, the new rates being $1.70 ℔ ton for prepared sizes, $1.40 for Pea, and $1.25 for Buckwheat. The Reading tonnage for week was 400,000 tons, of which 55,000 tons went to New York waters. Pennsylvania Railroad tonnage for week, 336,958 tons Coal and 112,824 tons Coke. Increase for one year 443,000 tons.

Financial.

With the gradual disbursement of some $50,000,000 in the shape of interest and dividends, due April 1, all the markets experience a sense of relief. The feeling of stringency prevalent of late in all directions has undoubtedly hampered trade to no small extent; as collections have been slow, merchants could not readily sell their bills because banks had not the money to spare, and accommodations of any kind were reluctantly granted. Even now the financial future is not cleared of doubt, for,

although Saturday's bank statement shows that the surplus reserve has increased and that loans were but slightly contracted, the renewal of gold exports shows that a plethora of money cannot be expected immediately. The hope of easier money and the chance of lower freight rates on the opening of navigation have both had a retarding effect. Bearing on the general topic as related to gold exports, Henry Clews says: "In view of the abnormally large stocks of exportable products, it seems almost inevitable that our exports must materially increase from this time forward; and if the exports should be proportioned to the over supplies, the outflow of gold might easily fall below the usual average. In other words, it is reasonable to suppose, all other things being equal, that during the next three months the merchandise exports will largely take the place of gold shipments." This view is strengthened by the lower price of wheat since the defeat of the Chicago clique, also by the break in pork and provisions, and the improved outlook for the foreign consumption of cotton, the export demand for these commodities having already revived. On Monday the failure of the Commercial Bank of Australia was used against the market.

Stocks, after a severe hammering, took a favorable turn, in prospect of easier money and large railroad earnings as a consequence of the World's Fair boom. On Monday Western stocks were slightly affected by the threat of engineers and firemen at Toledo to strike rather than to handle cars or freight of roads connecting with the Toledo, Ann Arbor & North Michigan. The news of the engagement of $1,500,000 gold for export to Europe had little effect. The decision of Judge Ricks in the United States Circuit Court at Toledo against the striking engineers imparted a firmer tone to Western railroad stocks. Manhattan was the feature, and was largely sold on the report that a syndicate is ready to provide capital for an underground rapid transit system. All the industrials were erratic. Cordage advanced rapidly and Chicago Gas was freely bought. Sugar was inclined to sag on the report of a proposed new investigation into the company's organization and methods.

United States bonds were strong at the the following quotations:

U. S. 4½s, 1891, extended	99½
U. S. 4s, 1907, registered	113
U. S. 4s, 1907, coupon	113
U. S. currency 6s	105

Chicago Report.

Scrap.—Iron and Steel stock are in fair demand again, supplies here being drawn upon for outside consumption. Dealers' buying prices are as follows:

	Per net ton.	Per lb
No. 1 Wrought Scrap	$13.00	....
Machinery Cast	10.00	....
Malleable Cast	7.00	....
Stove Plate (free of burnt)	7.00	....
Burnt Iron and Grate Bars	5.00	....
Sheet Iron and Hoops	4.00	....
Plow Steel and Breaking Stock	8.50	....
No. 2, such as Shovels, Hoes, &c.	4.50	....
Old Boilers—whole (Iron)	8.00	....
" (Iron)—cut in single Sheets and Rings	12 00	....
Old Gas-Pipe and Boiler Tubes	9.00	....
Cast Borings	5.00	....
Turnings	6.00	....
Horseshoes	12 50	....
Copper Bottoms	....	8¢
Copper Clips and Heavy	....	9½¢
Heavy Brass	....	8½¢
Light Brass	....	4 ¢
Pipe Lead	....	3 ¢
Tea Lead	....	2¾¢
Zinc	....	3 ¢
Rubber	....	2¾¢

Anthracite.—Local dealers do not anticipate any change in prices until toward the close of this month. Carload lots of 12 net tons are quoted as follows:

	Grate.	Egg, Sto. and Ch.
Chicago, Ill	$5.85	$6.10
Milwaukee, Wis	5.85	6.10
Kansas City, Mo	9.05	9.30
Council Bluffs, Iowa	9.05	9.30
St. Joseph, Mo	9.05	9.30
Leavenworth, Kan	9.05	9.30
Omaha, Neb	9.05	9.30
Burlington, Iowa	7.35	7.60
Des Moines, Iowa	8.80	9.05
Davenport, Iowa	7.15	7.40
Dubuque, Iowa	7.15	7.40
Madison, Wis	7.35	7.60
St. Paul, Minn	8.35	8.60
Lincoln, Neb	9.20	9.45
Sioux City, Iowa	9.05	9.30
Aberdeen, S. Dak	9.10	9.35

Colorado Anthracite.

COLORADO FUEL & IRON COMPANY.

Denver	$8.00
Pueblo	8.00
Colorado Springs	8.00
Leadville	8.00
Cheyenne, Wyo	10.00
All points between Denver and Missouri River	9.35

CONDITION OF THE

Hardware Trade.

REPORTS of the amount of goods distributed by the trade in all parts of the country continue good. Large quantities are now going into consumption everywhere. Indeed, many lines are moving off so rapidly that it is difficult to get orders promptly filled. This is particularly true in the case of seasonable goods. Manufacturers generally report a good volume of business, and very many are behind their orders. Collections, except in some localities, are fairly good.

Advices from Chicago.—The demand for Hardware is increasing steadily. Jobbers anticipate a very heavy April trade, looking for a great deal of business which is usually done in March, but which was checked this year on account of the prolongation of winter weather. Spring appears to have opened to stay, as over a week of mildness has now been experienced through the Northwest. The improved weather has brought with it a much better demand for Tin Plates, especially for ternes, as the construction of buildings is being vigorously pushed. Wire Cloth is exceedingly scarce, and is now held by jobbers at $1.40, with an advancing tendency. Stocks in Chicago are reported to be hardly equal to the wants of the city itself. The multitude of structures of all kinds now nearing completion on the World's Fair grounds and in the immediate vicinity has caused a very heavy demand for finishing Hardware, and many contractors are in straits because they cannot get supplies which they have deferred buying until they were actually needed.

Notes on Prices.

Cut Nails.—The demand for Cut Nails is being maintained extremely well, mills still quoting very generally $1.20 for carload lots at mill, although this price has been shaded in some instances. In New York the quotation is $1.40 for carload lots on dock and $1.60 from store.

Advices from Chicago.—Cut Steel Nails are slightly lower from factory, in sympathy with lower prices circulated by Wheeling makers, and can now be quoted at $1.35, Chicago. Manufacturers here are well supplied with orders for this month, but have deemed it wise to meet changing conditions elsewhere. Small lots from stock are selling at $1.50.

Wire Nails.—The manufacturers of Wire Nails held a meeting last week, at which it was decided to make an advance in the card rate to $1.55 f.o.b. at mill, with Cleveland as the point of equalization for the West and Pittsburgh for the East. This advance is smaller than was looked for at this time, and in view of the exceptionally strong position of this article it is not unlikely that another advance will be made before long. The demand continues very large. Small lots from store in New York are quoted at $1 80 to $1.85.

Advices from Chicago.—The Wire Nail manufacturers held a meeting in Cleveland last Thursday and advanced prices to $1.55, Cleveland and Pittsburgh. Reports made at the meeting showed an aggregate stock of only 100,000 kegs with contracts booked for over 400,000 and a good demand still coming in from large buyers. Conditions have seldom been so strongly in favor of the manufacturers. The advance made was very conservative under the circumstances. Reduced freight rates make the factory price equal to $1.67, Chicago, or only 3 cents advance. Another advance, however, is probable in the near future. Jobbers met on Monday and raised their prices to $1.75 for small lots and $1.70 for carloads. Those who persistently parted with their stock at very low prices, in competition with the manufacturers, now see the mistake they made.

Barb Wire.—The demand for Barb Wire continues good, and while there is no quotable change in prices a hardening tendency is noticed. We quote $2.45 @ $2 50 for Four Point Galvanized, in carload lots at mill. In New York the price is $2.65 @ $2.70 for carload lots on dock, and $2.70 @ $2.75 at store.

Advices from Chicago.—Barb Wire is in much stronger demand as the spring opens, and manufacturers expect shortly to have more business than they can well handle. Inquiries are coming in from all sections. Factory quotations are unchanged at $2.20 for painted and $2.60 galvanized, but it will not take much of an addition to the demand to push prices up. Jobbers quote small lots from stock at $2.30 and $2.70 respectively.

Rope.—During the past few days the fiber market has shown exceptional weakness. This is especially the case with

Sisal, and, though it has had as yet no appreciable effect on manufactured goods, it is thought that it may have very soon. New Zealand is of course in sympathy with Sisal, and should a decline in the latter be maintained New Zealand must follow. Quotations on Rope have so far been well maintained, and we have no change to note at the present writing.

Screws.—There are indications of a disposition on the part of some manufacturers of Wood Screws to be aggressive in seeking new customers, to whom they are offering unusual terms. This has caused a weakness in prices, and quotations are being made in some cases which are lower than any during the past few months.

Dickson Transom Lifters and Openers.—These goods are put on the market by the G. J. Dickson Mfg. Company, Albany, N. Y., W. H. Eckert, 18 Warren street, New York, agent. The self locking Transom Opener is sold at the following list, subject to a discount of 30 per cent.:

Bronzed Iron.

Diameter of rod.	Length of rod.	Length of arm.	Price each.	For extra length of rod per foot.	For extra length of arm per foot.
Inch.	Feet.	Feet.		Cents.	Cents.
3/8	2	1	$2.00	20	15
1/2	3	1	2.75	30	20
5/8	3	1	3.50	40	20

Nickel, brass, bronze and ebony plated, 70 per cent. more than bronzed iron.

Solid Bronze, Highly Polished.

Diameter of rod.	Length of rod.	Length of arm.	Price each.	For extra length of rod per foot.	For extra length of arm per foot.

Discount Sheet.—The Barnes Mfg. Company, Phœnix, N. Y., issue the following discount sheet, which applies to their 1893 catalogue and price-list. Terms, 30 days, f.o.b. factory:

	Discount. Per cent.
Phœnix Vises: All styles and sizes, including Case Assortments, Sample Blocks and Combination Pipe Jaws	33⅓
Pipe Vises	33⅓
Reinforced Bronze Metal Sash Chain	60&10
Reinforced Steel Sash Chain, either bright or copper finish	60&10&10
Victor Bronze Sash Chain	65
Victor Steel Sash Chain, either bright or copper finish	65&10
Sash Chain Fixtures	6
Plumbers' Chains—12 yard boxes or 500 feet reels; Basin, Wash Tray and Bathtub Chains; Brass Split Links; Brass Eight Hooks	New List 60
Lathe Dogs and Lathe Dog Wrench	50&10
Steel Machinists' Clamps	33⅓
Door Springs	33⅓
Door Stop and Holder	33⅓
Door Cheeks	33⅓
Barrel Trucks	40
Bench Anvils	50
Christmas Tree Holders	50
No. 1 Carpet Stretchers	40
Cork Presser	40
Mail Box No 1, with or without locks	33⅓
File Cards	33⅓
No. O Tack Hammers	40
Window Cleaners	40
Floor Scrubbers	50
Locking Chains	33⅓
Dog Leaders	40
Key Chains	40

The company issue under date March 9 a revised price-list of their Phœnix Plumbers' and Sash Chain.

Bright Wire Goods.—Prices in this line are irregular and competition is very sharp, resulting in lower quotations than have ever before been made.

Augers and Bits.—While manufacturers seem to be adhering strictly to their prices for Augers and Bits, many of the leading jobbers of the country show a disposition to undersell the manufacturers, and are quoting prices lower than the makers will sell at.

Shedder, Mane Comb and Sweat Scraper.—This article, which is manufactured by F. E. Kohler & Co., Canton, Ohio, is sold to the trade at $1.50 per dozen and $15 per gross.

Monarch Trouser Guard.—This article is put on the market by the Monarch Cycle Company, 42–52 North Halsted street, Chicago. It is sold to the trade at 75 cents per dozen.

Glass.—The local demand for Glass has shown no increase since our report last week, and while there is a moderate amount of Glass being sold, trade is far from being considered good. Factories continue to report no accumulation of desirable sizes in stock, with an increasing demand for their output. The capacity for producing American Glass at the present time is said to be the largest in the history of the Glass business in this country, the capacity now being equivalent to 1712 pots. Indications point to an increase in this number for next season. As this increase will largely arise from established concerns enlarging their plants, it would appear that makers familiar with the Glass business considered the outlook favorable for such extensions. Prices of American Glass remain unchanged as quoted. A committee from the National Window Glass Company held a conference on April 4 at Philadelphia with the New Jersey Glass manufacturers, with a view to getting them in the association, and the committee were expected to meet the New York importers of Glass in this city on the day following to come to some similar agreement with them. The New York French Window Glass Association agreed upon an advance in prices, to take effect April 3. The discount now in force is 75 and 10 and 5 per cent. from the French

list. While no official announcement has been made as to the plan adopted by which it is hoped to sustain prices, it is understood that a sum has been paid by each firm to the association which will be considered forfeited should prices be cut by any concern. The Plate Glass trade remains unchanged, the price and demand being satisfactory. The outlook for all branches of the Glass business is considered by those in the trade as encouraging, and the demand is expected to increase in the near future. We quote prices as follows: American Window Glass, 2000 boxes at one time, 80 and 10 and 10 per cent. discount; carloads, 400 boxes, 80 and 15 per cent. discount; less quantities than carloads, 80 and 10 per cent. discount. Freight allowed on car lots and over, not to exceed 17½ cents per 100 pounds; less than car lots, f.o.b. at shipping point. French Window Glass, 75 and 10 and 5 per cent. discount. American Plate ranges in price from 60 and 2½ per cent. discount to 60 and 5 per cent. discount. Imported Plate Glass, 60 per cent. discount to 60 and 10 and 5 per cent. discount.

Old Rubber.—The following are the current prices paid for Old Rubber delivered in New York:

Car Springs, in ton lots, ₰ lb.	....	@	$0.03½
Rubber Shoes, in ton lots ₰ lb.	....	@	.03

Trade Notes.

THE STANDARD STAMPING COMPANY, St. Louis, Mo., issue a 30-page illustrated price-list of Stamped, Pieced and Japanned Tinware of their manufacture, besides a variety of other goods that they handle. The first pages are devoted to Tin Plates and Sheet Metals and Tinners' Supplies. Then come Tinners' Tools and Machines, Milk Cans, Water Coolers, Oil Stoves, Oil Cans, Clothes Wringers, Plated Spoons, Bath Tubs, Wire Cages and a variety of other goods.

THE PROGRESSIVE tinware manufacturers, the Geuder & Paeschke Mfg. Company, Milwaukee, Wis., are evidently convinced that brevity is not only the soul of wit, but also of business. What they announce to the trade elsewhere in this issue is brief and to the point, and cannot fail to attract the attention of intending purchasers.

H. CLAYTON & CO., WM. VOGEL & BROS., selling agents, 37-47 South Ninth street, Brooklyn, N. Y., issue an illustrated price-list of patented specialties, including Sultana Sad Irons, Alcohol, Gas, Nursery and Volcano Stoves, Combination Stoves for gas or alcohol, Carpet Stretcher and Tack Holder combined, Fire-Place Hoods, Stove Pipe Shelves, Window Cleaners, &c.

A. B. FISHER, 385-387 Kent avenue, Brooklyn, N. Y., issues a catalogue and price-list of Culinary Brass Goods and Trimmings, including Gauge Faucets for coffee, tea and hot-water urns, coolers, refrigerators, &c. Urn Faucets, Side Handles for Urns, Knobs, Urn Feet, Milk and Liquor Faucets, Double-Acting Safety Valves, for preventing explosions or collapse of urns or boilers, Pipe Taps, &c.

WILLIAM VOGEL of William Vogel & Bros., manufacturers of Tinware, Brooklyn, N. Y., who left New York February 16, in search of rest and recreation, returned much pleased with his trip, April 5. He was accompanied by his wife and daughter, their journey extending as far West as California.

THE NATIONAL VAPOR STOVE & MFG. COMPANY, Cleveland, Ohio, make an announcement relating to the New Idea stove of their manufacture. They refer to its many excellent features and fredom from smell, either when in use or when extinguished. A picture of the stove is presented in the announcement and a list of wholesale agents given.

J. H. CORT & SON, 220 Water Street, New York City, are directing attention to the new style of hot plate with even top made in two sizes. An illustration in their advertisement shows the device.

THE CHEROKEE ZINC COMPANY were incorporated a few days since at St. Louis, Mo., with a capital stock of $300,000. We understand that the concern have acquired and consolidated a number of Zinc mining properties in Jasper County, Mo., the Joplin district, and smelters in Crawford and Cherokee Counties, Kan. They propose the further acquisition of properties, but at the time of writing, the details had not been made public. The capital stock is divided into 3000 shares, the bulk of which is held by Willard P. Heath, secretary and treasurer of the Kansas & Texas Coal Company.

AMONG recently authorized corporations in Illinois are the following: The American Car & Railway Construction Company at Chicago; capital stock, $1,200,000; for the manufacture of motors and locomotive engines, rolling-stock appliances and supplies for railways; incorporators, Watson Franter, William A. Conover and J. G. Wolfe. The Robinett Hydraulic Motor Company at Chicago; capital stock, $100,000; for the manufacture of hydraulic motors; incorporators, W. H. Robinett, C. W. Selfridge and George A. Masters Triumph Boiler Cleaner Company, at Chicago; capital stock, $30,000; for the manufacture of machinery; incoporators, Olin H. Johnson, George G. Williams and Fred. S. Benjamin. The Champion Self-Heating Sad Iron Company at Chicago; capital stock, $25,000; manufacture and sell sad irons; incorporators, Theodore Steuger, Thomas F. Powers and Harry F. Farnsworth. The Automatic Furnace Company, Chicago; capital stock, $50,000; incorporators, Charles F. Haines, C. S. Wallis and Charles M. Weaver. The American Smoke Preventer Company, Chicago; capital stock, $100,000; incorporators, William R. Mills, Charles Smith and Charles A. Pratt. American Steam Boiler Compound Company, Chicago; capital stock, $100,000; incorporators, William E. Deuer, William I. Cronin, Charles P. E. Dumas, Charles E. Coogan and James Young.

JAMES B. SCOTT & CO., Pittsburgh, Pa., favor us with several circulars and price lists that they are sending out. One relates to their steel roofing and siding, and they mention that a comparison of their price-list for 1893 shows a considerable reduction from last year's quotations, which is the result of careful calculation upon the basis of lowest cost and smallest margin of profit. Other circulars relate to Scott's Extra Coated Roofing Plate, and a circular of quotations on Sheet Iron is enclosed.

PATTERSON, GOTTFRIED & HUNTER, 146 to 150 Centre street, New York, have just issued a large catalogue, representing their stock of Machinery, Metals, Hardware, Tools and Supplies. The book is 10 x 13 inches in size, containing over 500 pages, substantially bound in cloth. Over 1,500 illustrations are shown, together with list prices and valuable tabulated matter; while the arrangement indicates much thought and labor. The index is very complete, occupying 20 pages near the front of the book. A careful study has been made of the requirements of machine shop, factory and mill, so that many goods not usually considered as belonging to these lines are now included. Many of the lists are given in a more compact form than heretofore, while others which were compiled separately are now grouped under one head. Descriptions in words have been so far as possible omitted, the dimensions and list prices being depended upon to give the necessary information, and the phrasing has been reduced to the utmost simplicity consistent with clearness and explicitness. A saving of space has resulted from omitting lengthy descriptions, and by throwing as far as possible, various tables into one, so that the book contains a large amount of matter, without giving the pages a crowded appearance. Among the goods listed, are Roll and Sheet Brass, Embossed Brass, Perforated Brass, Tin and Copper, Brazed Tubing, Wire, Steel, Screws, Bolts, Nuts, Nails, Tacks, Rivets and Burrs, Milling Cutters, Metal Saws, Gauges, Calipers, Steel Rules, Squares, Drills, Reamers, Taps, Dies, Screw Plates, Files, Checks, Wrenches, Clamps, Cutting-off Tools, Knurls, Mandrels, Dividers, Pliers, Vises, Chisels, Auger Bits, Carving Tools, Saws, Plumbs and Levels, Gas Burners, Measuring Tapes, Oilers, Fire Pots, Molders' Tools, Gas Blast Furnaces, Forges, Blowers, Lathes, Shapers, Shearing and Punching Machines, Grinding Machines, Pulleys, Gears, Belting, Brushes, Packing, Steam Gauges, Pipe and Fittings, Lanterns, Electrical Goods, Acids, &c. From the foregoing enumeration an idea of the range of the stock may be obtained.

THE CLINTON WIRE CLOTH COMPANY, Clinton, Mass., have a new mill in which they are putting looms for weaving Window Screen Cloth. The company have recently increased the force in the machine shop to upward of 30 men, who are now busily engaged in getting out the new looms. The estimated increase in production will exceed 10,000,000 square feet per annum. We are also advised that the Westinghouse Company of Boston are putting in the works two dynamos by which the seven mills will be equipped

with incandescent lights. The company are running double turn in several of their mills and on the fine weaving a very steady light is necessary, for if a wire breaks it must be seen instantly or the fabric weaving is liable to be ruined.

THE QUARTERLY ISSUE of the desk calendar of the Nubian Iron Enamel Company, Cragin, Ill., comes to hand, with the following sprightly introductory note by manager Chas. E. Bonnell: "When we last came to you with our New Year's Salutatory we were in the flush and heydey of the new year. '92 had been especially gracious, but since, we have been in sack-cloth and ashes, with the accent on *ashes;* we presume for appearance sake we should write in a lugubrious tone of voice, but we are naturally a sprightly and vivacious young thing, with a superabundance of animal spirits and we can't look blue; besides, the outfit was too small for us anyhow, and—well on the quiet, we were fully insured, but that, of course, is not the reason for our broad smiles and good appetite—it is because the 'still, small voice' whispers: 'Well done, good and faithful, &c.' you make *the best blacks on earth*, and that means—well, here's to you for the next three months." It evidently takes a good deal more than a mere fire to check the enterprise of this company.

AMONG THE ATTRACTIVE PUBLICATIONS for the present season is one issued by the Pope Mfg. Company, Boston, entitled "Out-Doors," a book of healthful pleasure. The work contains 77 pages, liberally illustrated, with articles on different sports by recognized authorities. Both covers are illustrated in colors representing some of the popular out-of-door recreations. The topics treated are Lawn Tennis, Yachting, Terrestrial Flight—Bicycling—Football, Baseball, Horsemanship, Health and Rowing, Recreation and Sport in Canoes. The advertising is all confined to a few pages at the back of the book.

NORTON EMERY WHEEL COMPANY, Worcester, Mass., have been allotted a space 37 x 10 at the World's Columbian Fair. The exhibit will be open on three sides, and will include various sizes and shapes of Emery Wheels and numerous Emery grinding machines in operation.

THE INLAND WHITE LEAD COMPANY, 149 and 151 Huron street, Chicago, have recently begun manufacturing operations outside of the combination. They will sell pure White Lead, White Primers and Putty in small lots to the Hardware and drug trade. Thos. S. Vaughan is president, and Benj. F. Hadduck is vice-president and treasurer.

EUGENE MUNSELL & CO., 218 Water street, New York, are increasing their facilities for manufacturing Micanite. It will be remembered this is a production for insulating purposes that is being largely used by electrical companies. By improved processes of manufacture waste mica, heretofore almost valueless, is being made into an endless number of forms and shapes, sheets that can be cut to size included. We are advised that orders are coming in very freely, and, while so far they have managed to execute them with reasonable promptness, they are being pushed to keep pace with the demand. Electricians have experimented with almost everything for this purpose, but have fallen back on mica, which for many uses has heretofore been unavailable on account of great cost.

THE DUBUQUE WHITE ENAMELING WORKS at Dubuque, Iowa, whose plant has been in course of erection for some months, turned out their first product on the 27th ult. It was pronounced of very high quality by those who had the privilege of examining it.

THE CLIFTON SPRINGS MFG. COMPANY, Clifton Springs, N. Y., are manufacturing an extensive line of Evan's anti-rusting Tinware and other Tinware specialties. Among these are included Pails, Sprinkling Pots, Dish Pans, Tea Kettles, Foot Baths, Toilet Sets, Chamber Pails, Commodes, Wash Boilers, Dippers, Cups, &c. They also make the Harland and Angle Faucet Oil Cans; Mrs. Van Deusen Cake Molds, Coffee Pots and Dinner Pails.

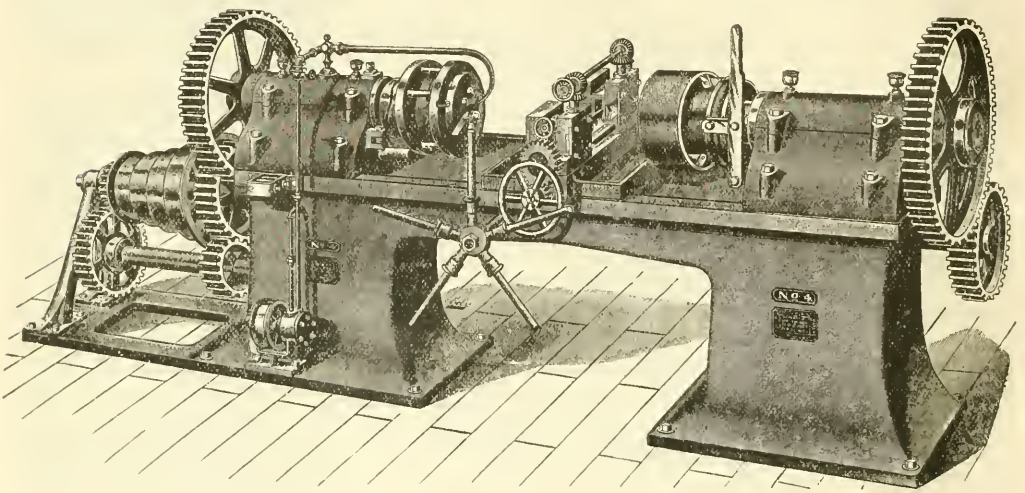
BELLAIRE STAMPING COMPANY, Harvey, Ill., are manufacturing a line of Columbian Enameled Steel Kitchen Ware, noticeable among which are tea and coffee pots. These are made with both tin and enameled covers. The enamel, it is remarked, differs slightly in appearance from other enameled ware on the market.

THE LONG ROOFING & CORRUGATING COMPANY, 416 East Ohio Street, Indianapolis, Ind., make an announcement elsewhere respecting corrugated standing seam and crimped steel roofings of their manufacture.

Capitol Pipe-Threading and Cutting-Off Machine.

The Capitol Mfg. Company of Chicago have made quite a radical departure from present methods employed in pipe-threading machinery, having adopted for this special service the methods used by them in threading and milling rods and bolts and cutting off iron and steel. Instead of revolving, the pipe being threaded, it is held stationary and the threading head, which contains the dies or chases, revolves. We have repeatedly referred to the principles involved in the design of the Adams automatic threading head, which the Capitol Mfg. Company used in their machinery. In this case it is simply larger in dimensions. It opens and closes automatically like the regular bolt-threading machinery made by the company.

By reference to the accompanying engraving, it will be observed that on the opposite end of the bed to the threading head is a chuck which grasps the pipe after the thread has been cut to proper length. One movement of the lever holds the pipe sufficiently well for cutting off purposes. The cutter itself is fastened in a holder which is located in the vise jaws on a carriage by the cutting head and the gripping chuck, as seen in the engraving.



THE CAPITOL PIPE-THREADING AND CUTTING-OFF MACHINE.

The cutter used for cutting off is a regular cutting-off lathe tool, while the vises on the carriage act as steady rests and are self-centering. The threading dies are flush with the head holding the same, and short pipe can be threaded on both ends its entire length. The cutting off tools can be moved to cut the pipe any desired length, and the machine can be used for both cutting off pipe into short or long lengths. The threading dies are just the same as those used on the Adams bolt thresding machines. They are durable and can be rebobbed several times.

Both spindles are hollow and are provided with collars on the inside to prevent the pipe from sagging or bending. The oil or lubricant required for threading purposes is held in the basin of the machine and is pumped by means of a rotary pump and used over and over again. The supply can be regulated to suit the requirements.

The machine takes up little room and

does the work quickly. The engraving represents the No. 4 machine with a capacity from ¼-inch to 4 inch pipe. The machines are made in all sizes up to 16 inches. The machine can also be used advantageously for threading and milling rods and bolts and for cutting of iron and steel.

Rubbing Out the Wrinkles.

Writing to *The Age of Steel*, Fred Woodrow says: It is a fad with many who are blessed with more birthdays than brains to spend money and time in rubbing out the wrinkles time has made on their would-be juvenile countenances. It is needless to say that a fool and his money soon part, and that the dream of returning youth is as artificial as the remedies that are bought with a dollar and repaid by repentance. What is true both of a fool and his face is equally so with others who, in other forms, attempt the same miracle. A man in business, for instance, engages in dishonest practices; it is policy, so he thinks, to do so. Others indulge in the same tricks, which, if successful, are rewarded by social distinction, and only in cases of failure are called by their proper names. There is no intention of perpetuating the larceny, the idea in nine cases out of ten being to retire into the shade with the stolen fruit and prepare for another world while masticating the plums obtained in this. The attempt is a failure. The evil has soaked into the bones and time has not enough of sarsaparilla to clean it out. The moral and mental nature are infected with the same disease, and the vice of trickery disguised under that modern heroic known as smartness, is a curse till death ends the comedy. The wrinkles refuse to be rubbed out.

Some men, born with a dry spot on their tongue which no success in life can irrigate, develop a spirit of selfishness that is supposably harmless and is no exception to the arid territory of his neighbors. It is not necessarily associated with dishonesty or any such vice as might be amenable to any law on the statute book. It commits no crimes in the domain of police authority or in reach of that scorching simoon known as public scandal. It simply locates everything worth having in its own vest. Its eye is keen and its throat of ample proportions, and sooner or later makes life a sponge that is never dry. A character made up of this absorbent is not easily changed. In a business sense it may or may not be a success, while in a character sense it is simply moral damnation. We have seen men of this formation in their later years endeavoring to change their habits as a youthful crab does its shell, but their fingers to the last struggled for the largest apple, and if they died in peace it was with the delusion of having a ticket for the softest seat in the invisible parlor. The wrinkle never rubbed out.

Some, and these are not in a minority, are simply indiscreet and careless. Prudence is a missing virtue. It has no place in their character. Their life alternates between the spring board and the penitent bench. They are tadpole and frog all their lives. In business their mistakes are as many as their opportunities, and each one of the continued series is interpolated with regrets and resolutions. The idea at the back of these errors is that in making a leap, if one lands in a mudhole a return jump will remedy the matter. The misfortune is that but few return tickets are issued on the other side. The losses that occur in business through this folly are by no means the smallest of its debits, nor is the evil at their root so rare as to need a Diogenes to find it. The spirit of recklessness and precipitation, though not exclusively, is yet characteristically, American. "Let her rip" is something more than a slang phrase, and is, in fact, a national motto. The results are weekly tabulated by Bradstreet or Dun, with not a few men in the country making more time than success in endeavoring to rub out the wrinkles.

The idea that the consequences of any folly can be changed as easily as a necktie is a grave delusion. With young men especially, who have teeth yet to grow and not a little to learn, the delusion is specially captivating. This or that habit is formed and this or that trait of character developed under the convenient or deceptive assumption that it can be as easily disposed of as an old glove or a hirsute bang. This is impossible. The evil cannot disappear in a sponge, or its consequences be averted by a resolution made on Sunday night. Character, whether noble or otherwise, is a growth and not a purchase. If this was considered as it ought to be, both in morals and in business, there would be fewer futile attempts at rubbing out the wrinkles.

NEW PUBLICATIONS.

FORTY-SECOND ANNUAL REPORT OF THE TRUSTEES OF THE SYRACUSE STATE INSTITUTION FOR FEEBLE-MINDED CHILDREN, for the year 1892. Albany. 1893.

The latest annual report of the beneficent institution at Syracuse which cares for the helpless and unteachable idiotic children of New York State shows that good work is being done in this direction. During the year 1892 541 children of this helpless class were sheltered in the asylum at a total cost of $92,635.64. Perhaps the most interesting feature of the present report is, however, the inquiry into the causes of typhoid fever, which has been epidemic in the institution during the three last years. The Syracuse Board of Health having discovered that the main sewer passed under the kitchens of certain of the buildings which were themselves pronounced unsafe, William Paul Gerhard, C.E., of New York was engaged to make an examination of the plumbing and sewerage systems; and his report occupies a large portion of the pamphlet. It was found that the pollution existed in two out of three wells which had been drilled in the grounds of the establishment after the city water had been pronounced contaminated, also that the sewerage system was imperfectly planned, and that the crude sewage was emptied directly into an adjoining creek, making its neighborhood quite unsanitary. Moreover, the storeroom and meat-room were exposed to the action of sewer air, which may have contaminated the food supply. The plumbing was, on the whole, found to be satisfactory and could not, in Mr. Gerhard's opinion, have contributed to the outbreak of typhoid fever. Since the inspection we learn that all Mr. Gerhard's recommendations for the alteration and removal of the probable causes of infection have been carried out.

According to a European exchange, a Frenchman, M. J. Novel, has invented a new process for soldering aluminum and other metals. The soldering material is stated to be very consistent and easily and quickly applied, while it leaves the metal uninjured. This solder is claimed to be cheaper than any material at present used for this purpose, and it possesses the advantages over acids and other substances of not oxidizing the metal and of being itself not liable to deterioration. It can also be used for coating aluminum, if necessary, and is capable of soldering the aluminum to either iron, tin, zinc, copper, steel, brass or nickel.

Trade Education for Young Plumbers.

It is an encouraging sign of the times to note how employers of skilled labor are turning their attention to the advantage of trade or technical education for the young mechanic of the present, so that he may in the future be in a position to come up to the progressive requirements of the age. Within the past few weeks several of our correspondents, notably those engaged in the plumbing and tinning trades, have been deploring the existing tendency to neglect the helper (the plumber or the tinner of the future) and allow him to pick up his trade as best he may without much, if, indeed, any assistance from either the foreman or the master. The existence of this interest in the young mechanic of the period is largely due to the action of Col. R. T. Auchmuty in founding the New York Trade Schools 12 years ago. While technical or theoretical education is of great value to members of every trade, it is indispensable to the boy or young man who adopts the plumbing trade as his life-work, because of the responsibility which it will bring in the future. The health of the community depends so largely on the sanitary condition of our homes—for which the plumbing work is largely responsible—that the coming plumber will be held to a strict accountability for the results of his work. In order to provide worthy successors in this important field of duty, the plumber of the present should take time by the forelock, and adopt some means of imparting necessary information to those under him as to the "why and wherefore" of plumbing, the theory on which it rests, and the operations of natural laws with which its work should be in harmony. It should be stated that a large proportion of the prominent master plumbers of the country have been won over to the cause of technical or trade educa ion, and that in certain of the large cities the establishment of the trade school is an accomplished fact. But outside of these centers of industrial progress, the plumbers' helper—sometimes called, by courtesy, the "apprentice"—is, for the most part, practically outside the pale of trade sympathy, and is considered in the shop as of no practical account beyond what work may be got out of him.

The Master Plumber as an Educator.

It may be in order just here to inquire how the plumber's helper is expected to get a knowledge of the trade which he hopes one day to follow. It is a settled thing that a boy must be at least 16 years of age before he becomes a plumber's helper. He is expected to "carry the bag" for the journeyman, to do all sorts of errands and be the drudge of the establishment. If he is bright he may pick up some knowledge of how to do things, but why they should be done in that particular manner and what the consequences would be if done otherwise he has to find out as best he can. When four or five years of this sort of work is completed the boy, now come to man's estate, gets his "tools" and takes rank as a journeyman, with little knowledge to fit him for properly undertaking a job of plumbing work beyond the merely mechanical part, proficiency in which, according to his conception of the term, makes him what is known as a "practical plumber." The trade school, where available, supplies the remedy for this state of things, but unfortunately at the present time the scope of that useful institution is, as already stated, limited to a few cities, and the aspiring young mechanic located elsewhere is left to circumstance to acquire the needed information. This is where the opportunity for the master plumber comes in, and it should, in the interest of the trade and the community, be utilized. There should be no better plan for making a good plumber out of a young man than working in the shop or on a job during the day, and doing some study at night which would make plain the work of the day. The master plumber should aid his young men in this work and as far as possible encourage it. The supply of useful elementary books would be of comparatively trifling cost to him but would be of immense benefit to his employees, and the display of even a moderate amount of interest in their advancement would bring its recompense in a closer attention to the work intrusted to them and a greater ability to perform it properly.

Wages and Expenses in America and Europe.

An interesting light is thrown on the question, as to whether the workingman in the United States is in the end better off financially than his European compeer, in a recent report laid before the Royal Commission on Labor by the British Foreign Office. The report deals very comprehensively with the industrial conditions obtaining in the United States, as compared with those in Great Britain and Belgium, and shows the relative wages earned, together with the cost of living in the three countries. The data presented having been presumably gleaned from reliable sources, a brief review of the figures and facts brought out in the document in question will be interesting and instructive, in view of the misapprehensions which exist in regard to the question. Iron and steel workers were selected as a fair average class, which in all three countries possess the status of skilled workmen. From the statistics offered, it appears that the average yearly income of an American employed in the iron and steel industries is $513.52, while that of a family in the same line—that is, in a case where a man is assisted by his wife or one child, the income is slightly larger, namely, $591.61. In Great Britain a family income in the same trade averages $456.86, while in Belgium it is only $374.53. To offset this, however, some living expenses in the United States are greater than they are in Europe. House rent, for example, averages $65.02, as against $38.35 in Great Britain and $31.72 in Belgium. Taxes and subscriptions to labor organizations cost more than they do in Europe.

Comparative Cost of Necessaries.

The outlay for food in this country is not quite so disproportionate, but it is, nevertheless, greater than in Europe. Each family of iron workers in the United States spends on an average $243.65 annually in nourishment, while on the other side of the Atlantic the average expenditure on this account is $222.52. The quantity and quality of the food obtained in this country is, however, probably much superior to that used by the European workman and his family. In other words, the American artisan lives better than his fellow in England or Belgium. The average expenditure under the head of intoxicating liquors by a workman's family in New York is $35.14, being a fair medium between $61.73 in Illinois and $8.08 in Virginia; while the drink bill of an English workman's family averages $21.86, and that of a Belgian, $9.66. The American workman spends less on amusements than does his European contemporary, while the annual expenditure for books and newspapers is about the same in America and England. To sum up, the average excess of income over expenditure of 511 families in the United States was $99.23, while the average deficit of 1249 families was $64.75. In Great Britain the average surplus of a number of families was $47.02, while in Belgium it was $22.24. On the whole, the statistics presented about point to the conclusion that, although British and Belgian iron workers have some advantages in the matter of cheap living, these do not by any means counterbalance the higher wages earned by similar craftsmen in the United States.

Steam Specialties.

Nothing indicates the inventive character of the age more than numerous contrivances designed to reduce the labor of attendance upon steam boilers, whether

used for power or for heating purposes. A great many instances of a double use of steam boilers, both for power and heating, now exist wherein the exhaust steam, after having developed power in an engine, is utilized for heating. Even where condensers are employed a double use of the same boiler for heating and power is occasionally met with, either high-pressure steam being directly used in coils or radiators, or live steam reduced to a pressure much lower than that used in the boiler, through the aid of a pressure-reducing appliance.

Wearing Out and Rusting Out.

Every one is familiar with rust and knows that it puts in its work quietly and often when the substance affected is not in use. Many people who have hot air furnaces need to be told that the spring is the time to take down the smoke pipe, clean it thoroughly and put it away until fires are wanted in the fall. While it is connected with the chimney flue the dampness collects and corrodes the inner surface and the old accumulation of soot is kept damp and destructive. This work must be done once each year any way to save the corrosion of five or six months of time when it is out of use and when the injury is greatest. Stoves and pipe are getting their worst wear also in the idle season and need to be wiped over with an oiled cloth and put in dry places. The wash boiler rusts out in the time it is out of use, if not thoroughly dried. Cutlery should be carefully wiped with a chamois as often as it is handled, and so on to the end with all goods that have polished surfaces. Nickel plate on stoves is easily kept bright if often wiped off and not allowed to corrode. The tin roof is not injured during a rain storm and should be painted as often as it becomes bare in spots. In the tin shop, the tools brought in after use outside in wet weather should be carefully cleaned and then a square will show its figures—as many do not—and the other hand tools will do their work easier and better. If it is inevitable that a man rusts out by idleness sooner than by wear, it is equally true of many articles?

A Western Foundrymen's Association.

We have been requested by prominent Western foundrymen, says *The Iron Age*, to assist in the development of a sentiment favorable to the establishment of a foundrymen's association at Chicago. The request is one with which we do not find it difficult to comply. There is no reason why a good strong organization of foundrymen should not be established in the West. The manufacture of castings for all purposes has grown there to immense proportions, the growth having been especially rapid in recent years. This has made the Western foundry interest numerically large. The scope of the work done is equal to that of the older sections of the country, and in some respects the practice is in advance of that obtaining elsewhere. The West is unconventional in almost everything, and hard and fast rules are not there regarded with the reverence displayed in too many old manufacturing localities. New methods are tried in foundries, and results are often accomplished which startle a hard-headed veteran who thinks he learned it all 40 years ago. At one time there was much criticism of Western work, which was strong enough and answered the purpose but lacked the smooth finish, the careful fitting and the general nicety found in castings turned out by crack Eastern concerns. This was, of course, due to the push and haste, so characteristic of Western life generally, when time was deemed too precious to be wasted in mere frills and furbelows. A change has been made in this respect as in others, and increasing attention is constantly being paid to the details which were once so neglected.

The most progressive foundrymen are among those who are most in favor of an association which shall have for its main object the improvement of foundry methods, to be attained through the mutual interchange of practical ideas. It is thought also that the commercial side of the business need not be neglected, but that more intimate acquaintance and better comprehension of trade conditions would prevent much of the very severe competition which almost wipes out the last vestige of profits. An association of this character could not regulate prices, as that would be wholly outside of its province, but a salutary effect might be exercised in the direction of conservatism. A room in some central location, open daily for the use of members, would be found a great convenience, the value of which would steadily appreciate.

The question naturally occurs: Would not such an association prove of value in the case of wages disputes? Experience teaches that the two cannot be well combined; that an association for the improvement of its members should have nothing to do with the settlement of labor troubles. It should be purely technical or educational, with regular meetings for the reading and discussion of papers or for reports of committees appointed to conduct tests or investigate new methods. The consideration of wages or other questions directly connected with the regulation of employees should be left to individual manufacturers or else should be taken up by a special organization for that purpose and for no other. The stove manufacturers arrange their affairs in this way, having found it vastly more satisfactory to handle strikes by means of a special organization than through a general association. One great objection to the latter is that many manufacturers prefer to adjust their own labor troubles and will have nothing to do with an association that assumes to take cognizance of such matters. A technical society should therefore be free from such entanglements.

We would suggest to those desirous of forming a Western Foundrymen's Association that reams of paper can be consumed in advocating it and yet no practical results be attained. The plan to be pursued is for a few prominent manufacturers to get together and issue a call to their fellow foundrymen to attend a meeting at a given time and place for the purpose of forming an association. If to such a beginning can be added the selection of a live, well-informed, and above all thoroughly-qualified foundryman as secretary, who will at least for a time furnish lots of practical ideas evoking interesting discussions which will attract a good attendance at the meetings, an association can be started that will be a credit to the men who mold iron in the West.

The Boss's Lament.

BY TINK.

Oh, what has become of the tinner of yore
Who learned his trade up over the store?
Who worked for the boss with interest and love,
Did the chores at the house as a part of the trade,
And took pride in seeing that things were well made,
And with his three years of apprenticeship passed
Sought a job as a jour., and could work very fast;
Took pride in seeing six dozen pans nest,
Could raise a tin cover, or teakettle breast,
Would whistle and sing as he soldered the seams
In pans, kettles and boilers, and all such things;
And when sent on a job would strike a good gait,
And took extra care to never be late,
But at seven o'clock would off with his coat
And go at his work as though work was a joke.
I'm afraid he is dead, in fact I'm quite sure
That his place is now filled by a new-fashioned jour.,
One who worked six months and finished his trade,
Then travels on cheek from one town to another,
Laying tin here and there, and don't care which or tother,
Can't make a tin cup water-tight if he tries,
Only puts in his time till the ten hours are spent,
And leaves for the next town with nary a cent.

What Shape Should Chimneys Be?

The same query applies to hot-air flues as well, and it was put and answered very positively by a man of a wide and successful experience as follows:

"Having an idea that it was not all uphill work in a chimney I concluded to investigate the operation of the one in my house to see if there was any down currents in it, as I had heard frequently asserted. I took light tissue paper and made some small light balls of it. I was particular not to crush them tight and make them heavy, and also was careful to keep them round. With these I went to the top, and balls that were dropped into the center of the chimney were invariably blown out. Those dropped into the corners in a majority of cases went to the bottom, where I found them on taking out the pipe to look for them. Those that did not go down I think struck some projection and were thrown into the central up current and blown out. This settled in my mind that rectangular flues were wrong, and while the area of a round flue of the same diameter might be less it was equal in air-carrying capacity, as it had only one up pressure, with no corners for friction and tendency toward a vacuum. This led me to making the ends of my partition hot-air flues round, and while they are easier to make and cheaper they are equally as effective as if they had square corners, satisfying me that all flues should be round."

From another equally experienced source this idea has been expressed:

"I believe that in two houses of exactly the same build and exposure, except that one has partition flues for heating and the other round flues of liberal capacity, the house with the round flues can be heated satisfactorily for the six months necessary with at least a ton of coal less, and possibly with a 32-inch portable furnace where the other house would not be as comfortably warmed with a 36-inch furnace of the same make using the extra ton of coal and possibly more."

These views of practical and experienced men on a subject of so much interest to the trade open up a question that might be discussed with advantage.

THE LETTER BOX.

Better Education of Tinners' Apprentices.

From M. C., *Spokane, Wash.*—In *The Metal Worker* of March 25, "J. D." St. Louis, Mo., says he finds it impossible to obtain a tinner who understands his business. Perhaps "J. D." is an exceptionally fine mechanic and very set in his ways, and would find fault even with the man who had taught him the trade (if he is a mechanic) because he did not happen to know how to do something which "J. D." has learned since. On the other hand, he may expect to obtain a first-class mechanic for a mere song—and sing the song himself. I think good mechanics are to be had if "J. D." will pay good wages; I will warrant that he will not have to go out of his city to find competent men and as many as he wants, if he will pay 25 cents per day above the regular standard wages and use a man civilly.

The Metal Worker says that there is a general complaint coming from business men of the West, because of the lack of good, competent mechanics. I would like to know from what part of the West these communications come. I am inclined to think they come from Dakota, Iowa, Kansas, Missouri and Texas. I cannot see where else they can come from. I have been a reader of your paper for the past eight years, and during that time I have read of very few people in Montana, Washington, Idaho, Oregon, California, Utah or Colorado who wanted good mechanics. Perhaps they are dissatisfied with their men and are laying wires for a good supply. At any rate, they say nothing here about being dissatisfied. I would suggest that your correspondent try paying more money and then good mechanics will not be so apt to move to some State where they pay higher wages. I do not deny that there is room for vast improvement in our line of business by most of us; yet I think there are a good many good mechanics on earth. It requires a good deal of time and study to be master of as many trades as some people who use your want columns seem to think a tinner should possess. Here is an example: "Wanted. A tinner who can do plumbing, steam and hot water heating, also stray jobs of gas fitting and put in electric bells, put up wind mills, and during harvest go out and run a self-binder and explain all its mysteries. Will pay $9 a week to good man." Is it any wonder that good men who understand their business are scarce?

New Roof Over Old Roof.

From R. J., *Pulaski, Va.*—Will you kindly advise me in the following case: There is a flat-seam roof which has worn out and I am to re-cover the building with a standing-seam roof. It has a fall of 1½ inches to the foot. Would it be advisable to cover over the old tin or take it off.

Answer.—It is best to take off the old roof as the new tin can be laid faster and better, beside none of the seams or lumps in the old roof will remain to make trouble in the new roof if it is walked over, nor will there be nearly so much condensation as there would be between them if the old one remained. If two thicknesses of roofing felt were laid over the old roof before putting on the new the objections stated would be overcome. We have in mind a roof laid 14 years ago where the new roof was put on over an old standing-seam roof, the seams being flattened down and paper used between, which is still in good condition.

Making Solder Drops.

From OLD TIMER.—I send you a sketch, Fig. 1, of the way I make solder drops for soldering where it is not convenient to use a bar, or to take up the solder on the

Making Solder Drops.—Fig. 1.—Pouring the Solder.

copper. There is no secret about it, and many of your readers have made them, I presume, but others may not have known of this simple and quick way. Melt the solder in a ladle and pour a fine stream from the sharp lip into a pail of water. The solder must not be over hot, and the size of the stream will determine the size

Fig. 2.—Solder Drops, Full Size.

of the drops. Hold the ladle about 6 inches above the water, and it will at once be seen in pouring if all is right. The shape is oblong, and pointed at the ends, as in Fig. 2, and the drops lay much closer in corners on work than those made from the point of a copper, while the process is ten times faster.

Sweating Roof.

From J. H. W., *Williamsport, Pa.*—In reply to "G. W. B.," Newville, Pa., whose inquiry appeared in *The Metal Worker* of March 11, I presume the tin he speaks of is on the lower part of the roof or near the drip, and the iron roof is next and runs up to the highest point. I also assume that the ceiling below is plastered and that the space between the ceiling and roof is air-tight. If these are the conditions I would advise "G. W. B." to cut one or more holes in the highest part of the roof, say 8 inches in diameter, and put in a galvanized iron pipe with a hood on top, fastening it to the roof. The pipe need not be longer than 12 inches, so as to keep out the snow. There should be one pipe to every 20 feet square of roof, and I feel sure that the trouble will cease as soon as it is done; at least this is my experience in similar cases.

The cause of a roof sweating is the extreme cold outside and the pent-up air between the joists and rafters becomes warm, and coming in contact with the cold metal it condenses the moisture, which begins to drop down.

Does It Pay to Do Good Work?

From J. T. H., *Washington, D. C.*—"They have no incentives to push them on, and consequently are content to remain as helpers." The above is the conclusion of an article in the Letter Box department in *The Metal Worker*, March 25, and I would like to see the employers and employees discuss the matter, so that we may see if it has not a wider application than to the boys who are learning the trade. There are necessary evils, and nowadays, when low figures and ruinous competition control the bulk of work, I would like to know if the botch workman is not a necessary evil. However, it is the educated botch that is in demand. I find that the mechanic who is able to do his work quickly, slighting it in every possible way, and yet have it appear well (like some of the solder we buy, which has a good face, and is practically worthless) is the one that is preferred by employers. I have known in many cases, and it happened to me when a journeyman, that employers would complain if work was done well, and would advise their men that quantity was more to be preferred than quality. I have heard employers complain that they could not get paid for doing good work, and I know it to be a fact, particularly in the roofing trade, so much so that I have almost had to sacrifice this branch of my business, because I hold up for reasonably good work, for which but few are willing to pay. Does it pay a man to do work that gives more than temporary satisfaction? It is well known that the jobbing branches of the mechanical business are profitable, and I have heard bosses, as well as the men, reason that they did not want to do work that would last longer than a short while; that only a few would pay for good work, and that they could reap better harvest for repairs, and that the losers through bad work were those who were not willing to pay for good. Regarding the above logic from a purely selfish standpoint, I would ask, does it pay better to be a botch than a workman? I should like to see the matter discussed, that I may see if these points are well taken. Mechanics cannot afford to be philanthropists, and they certainly cannot have a proper regard for good work unless a fair price is paid for it.

Expansion of Iron Pipe.

From W. N., *Washington, D. C.*—Can you give me the following information? How much expansion will occur in a 6-inch iron pipe 100 feet to 500 feet in length at 20, 40 and 60 pounds pressure?

Answer.—One hundred feet of iron pipe will expand 0.008 inch for each increase in temperature of 1° F. This is the basis of

a calculation from which it will be easy to figure out an answer to our correspondent's inquiries. We assume that he wishes to know the expansion from ordinary temperature to the temperature of steam at 20, 40 and 60 pounds pressure. The temperatures to correspond to these three pressures are approximately, 259°, 287° and 307° respectively. Assuming the temperature to start with to be 60°, the increase of temperature of steam at 20 pounds will be equal to 199°, which would be equivalent to an expansion of 1.6 inches in 100 feet of pipe. The increase in temperature at 287° from 60° would be 227°, which would bring about an expansion of 1.8 inches in 100 feet of pipe. The increase in temperature to 60 pounds, which is 307° would be 247° amounting to 1.98 inches in 100 feet. In 500 feet, the quantity would be five times as great, or 8 inches for 20 pounds pressure; 9 inches for 40 pounds pressure and 9.9 inches for 60 pounds pressure

Quality of Water from Radiator.

From C. R., *Utica, N. Y.*—I am desirous of heating my bathroom from the kitchen range. This, of course, is easily accomplished. What I wish to know is, will such a connection when made spoil the water for washing or for culinary purposes? Will not the iron rust affect the linen, and how can I overcome the difficulty if I so heat the bathroom?

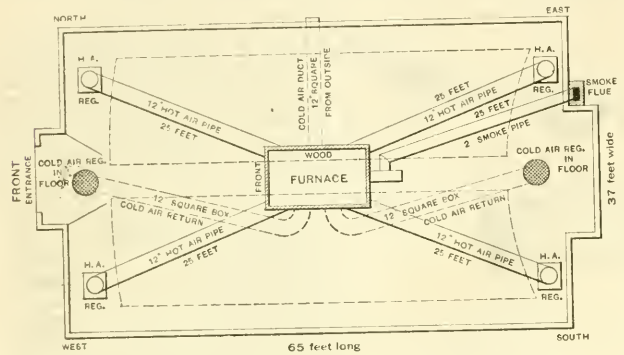
Answer.—If the amount of water in the system referred to by our correspondent is considerable we do not believe that there will be any more annoyance from the rust in the water than in ordinary cases where the water is delivered through iron pipes. The chief source of trouble is likely to be, that after the warmed water has been standing in the radiator and pipes for a considerable length of time, it will become enough contaminated with rust to stain linen, and at the same time be noticeable if used in cooking. Our correspondent need not be reminded that in a water system, the water for drinking and other purposes is often carried through many miles of cast-iron pipe without being appreciably affected by the rust. This is not exactly parallel, for the water being heated would have a more corrosive effect than if carried through the city main. A great deal, furthermore, depends upon the quality of the water in his locality.

Warming a Church.

From W. D., *Oxford, N. S.*—Inclosed please find the plan of a church heated by a wood furnace which was put in some time ago, but does not heat satisfactorily. It is large and capable of heating a building much bigger than the one shown by the plan. I have an idea of my own on this matter, but would like to have your opinion through the columns of *The Metal Worker*. The smoke pipe is connected to the flue on the outside, running through the cellar dug out underneath the church, and is not encased.

Answer.—The plan submitted by our correspondent shows the location of the furnace, the smoke flue and various other necessary fixtures, with their dimensions. While it would be desirable to know the depth of the cellar, hight of the ceiling in the audience room, and hight of the furnace, the details given are sufficient to show that care has been taken and that good workmanship has been employed, so that the trouble lies in planning the job and not in the execution of the work. A better flow of hot air through the 12-inch pipes could be secured by making the two cold-air return boxes or ducts equal in capacity to the four 12-inch hot-air pipes. The cold-air register faces must be of ample capacity to allow this quantity of air an easy passage to the two ducts; also enlarge the cold-air duct through which the air is taken from the outside, to equal in area three-fourths the combined cross area of the four 12-inch pipes. These changes will improve the flow of hot air, but not to the extent which will be required to heat the church in a satisfactory manner. Assuming that the ceiling of the church is at least 15 feet high above the floor, the total cubic space to be heated would amount to 36,000 cubic feet. To perform this amount of work properly would require four pipes, each 15 inches in diameter. The cold-air duct from the outside of the building to the furnace should then be 477 square inches in area; a cold-air duct, 32 x 15 inches, would be about the proper proportion.

The two cold-air return pipes or ducts should each be equal to two 15-inch pipes—that is, 354 square inches in area and provided with a suitable register face in the floor. Properly placed division plates must be provided in the furnace setting, so that the currents of air from the ducts will not interfere with each other, before they come together in the hot-air or mixing chamber. The hot-air or mixing chamber should be at least 12 inches high above the top of furnace. Suitable dampers should be placed in the cold-air duct and also in the return pipes, so that the flow of air can be regulated. The hot-air pipes should have at least a rise of 1 inch in every 12 inches from the furnace to the hot-air registers in the floor, and when the length of the pipes is so near the practical limit more rise should be given. If the cellar is a very cold one they should be well wrapped with a non-conductor to prevent any undue loss of heat from this source. To provide a good draft, the chimney must have ample area, and the smoke pipe, if necessary to prevent its becoming cooled before it connects to the chimney, should either be encased by a larger pipe or otherwise protected. If it is allowable to place the hot-air registers in the side aisles, this should be done, as it would shorten the hot-air pipes with great advantage and increase their rise as well as the distance between the hot-air registers and the cold-air return.



Warming a Church.—Plan Showing Furnace Pipes.

Dimensions of Ice Cream Freezers.

From W. S. C., *Tallahassee, Fla.*—A number of tinners would like to be informed through the columns of *The Metal Worker* regarding the diameter and hight of ice cream freezers ranging in size from 1 to 20 quarts.

Answer.—The following measurements of the tin receptacles for ice cream have been secured. It will be observed they are larger than the indicated capacity:

Size. Quarts.	Diameter. Inches.	Hight. Inches.
1	4	5¾
2	4⅝	7¼
3	5⅜	8¼
4	5⅞	9½
6	6¾	10½
8	7¼	12
10	7½	13¼
14	8	17¾
16	8¼	19
20	8½	21

The wooden ice tubs are made somewhat higher than the freezers, and from 3 to 5 inches larger in diameter.

Some Tin-Plate Queries.

From M. A. D., *Neenah, Wis.*—I have been using American tin plates and find them satisfactory, but it puzzles me to see them put up in the same kind of boxes as the imported plates, and think perhaps that they are not made here. I never knew the kind of wood tin-plate boxes were made of, but always supposed it to be a kind common in Great Britain only. Is there any tin in the coating of roofing plates?

Answer.—Some American tin-plate manufacturers use imported black plates, which are received by them in the usual tin-plate boxes. After dipping and finishing these plates they ship them to customers in the same boxes, merely as a matter of economy. Our correspondent may have received some of these. American tin-plate boxes are now usually made of pine, although some have only pine tops and bottoms, while the sides and ends are made of refuse hard wood, bought cheap in lumber districts. The Welsh boxes are made of beech and elm, native to the locality. They are sawed and made up green, then left to dry for packing. The quantity of tin in the coating of roofing plates varies. There is always some used. In the brighter-looking grades as high as 33⅓ per cent. of the coating is tin, the remainder being lead.

WORLD'S FAIR NOTES.

Perfection of Transportation Facilities.

Work has been hastened on the various lines by which the fair grounds will be reached from the heart of the city of Chicago. Those who have suffered from the annoyances of inadequate transportation on similar occasions will be interested in some of the details.

The Illinois Central Railroad, is of course, far in the lead of any other means of passenger conveyance. Additional tracks have been laid on this road, and for a considerable distance the entire roadbed has been elevated so that the World's Fair service can be performed without interference with the railroad company's immense general business and also at a high rate of speed because there are no crossings. The outlay by this company in merely making preparations for World's Fair local traffic has run up into millions.

The South Side elevated railroad has just completed its extension into the grounds, and is arranging to carry passengers from the business center of the city by rapid trains and to land them in the midst of the great fair buildings. On Dedication Day last fall, this road, then in operation from Congress street to Washington Park (Fifty-fifth street), carried within a period of 12 hours 115,000 people. Its equipment then was 85 cars and 19 locomotives; it has now 180 cars and 46 locomotives. The station of this railroad within the grounds will be an elaborate structure, with a capacity of accommodating perhaps 35,000 persons an hour. Outside the gates at Sixty-third street will be the Stony Island avenue station, with a capacity for accommodating 10,000 more.

"We have arranged our traffic programme," said President Barnard, "so that we will run through trains from Congress street, Twelfth street and from Thirty-ninth street, south bound; and from Jackson Park station and Stony Island avenue station, north bound. They will run perhaps one minute apart. The road is in thorough order; it is being equipped with the union switch interlocking system at all points where the tracks cross each other. We are now putting in electric light plants not only for all stations, platforms and yards, but also for all switch and target lights for our entire system; finding this much cheaper as well as more efficient than gas. Under these conditions the road has a carrying capacity—running trains one minute apart, which is well within the limits of safety—of 40,000 people an hour each way."

In the south division of the city, where Jackson Park and the World's Fair are situated, great demands will be made on the resources of the cable and horse car systems to take care of the unusually large proportion of passenger traffic which will fall to them during the six months of the exposition. The Chicago City Railway Company (the name under which the South Side cable and horse car systems are managed) are making preparations for the extra demands on their service. The two systems comprise not less than 152 miles of track which gridiron that part of the city pretty thoroughly. Twenty-nine different lines are operated on as many different streets, and the company have at their demand nearly 2000 cars, including those for their new electric lines.

The two big cable lines of the company, namely, the Wabash avenue and the State street lines, will be the great feeders of the fair grounds, while the radiating lines will be like veins contributing to these main arteries. Last October, at the time of the dedication, only the Wabash avenue line was available for feeding the fair grounds. The State street line is to be made also available by May 1 by connecting it with an electric cross-town line at Sixty-first street. Speaking of the enlargement and extensions which the company are making in preparation for May 1, Supt. M. K. Bowen said:

"We will have in operation a high-speed electric line from State street to midway Plaisance by May 1. Each motor car will have two trailers, and the capacity of the line will be sufficient to take care of all passengers transferred from the State street cable. The round trip from State street to Midway Plaisance, a distance of a mile and three-quarters, will be made in about 20 minutes. For the special accommodation of Englewood traffic another electric line will be opened at the same time on Sixty third street, running to the fair grounds, making a loop at the Sixty-fourth street gate. This will be a high speed line also, but the motor cars will have no trailers. Both lines described are built under the Westinghouse trolley system. Extensions have been made to our Thirty-fifth and Forty seventh street cross town lines, and they will be operated as electric lines after May 1 Last October, on Dedication Day, we moved about 750,000 people, using only closed or winter cars, each of which seats only 26 persons. Now, our open or summer cars will each seat 50 persons, and the World's Fair months, from May to October, will allow us to use both summer and winter cars. In my opinion we will be able to handle three or four times as many people per day as we did on the big day of the dedication season last October."

In addition to these facilities the Northern Pacific Railroad will run trains from the West side of the city direct to the grounds, and numerous boats will carry passengers by lake.

Missouri's Exhibits.

Missouri, the fifth State in wealth and population in the union, bids fair to become one of the first in the number and excellence of her exhibits at the Exposition. The exhibits of this State will embrace the departments of agriculture, horticulture, minerals, forestry, live stock, manufactures, liberal arts, fish and fisheries, ethnology and archæology, wool and dairy.

J. K. Gwynn, the executive commissioner of the Missouri State Board, says the Chicago *Record*, has been untiring in his efforts to promote the success of the State's showing.

"The Missouri State Building," he said, "is of the Spanish renaissance style of architecture and will not be used for exhibition purposes. In the finishing of the building a large variety of native structural materials, such as hardwoods, limestone, sandstone, marble and onyx, have been used. The building promises to be an exceedingly popular headquarters, aside from its entertainment of Missourians. The Commercial Travelers' Association has been assigned quarters in this building. The reason of this is that the president of this order happens to be a Missourian, hence the propriety of assigning the national organization of commercial travelers a home in the Missouri Building. The quarters of this organization will be handsomely furnished, and elaborate preparations are being made for the entertainment of the members of the fraternity who shall attend the fair.

"The executive commissioner of the State of Missouri is the secretary and treasurer of the national executive officers, so the Missouri Building becomes the headquarters of this organization, the object of which is to promote in any way the best results of the States and Territories whose executive officers are members of the association, and also to cultivate fraternal relations with the representatives of foreign governments making exhibits at the fair. Thus it will be seen that it would be difficult to devise ways and means to more fully popularize a state building than have, by accident, as it were, fallen to the lot of the Missouri Building.

"Missouri is, perhaps, more celebrated for her mineral wealth than any other one product of the State. Iron Mountain is known the world over. However, while more famed for this celebrated mountain than for any other one feature, iron is by no means the most important mineral product. Missouri now produces two-thirds of the zinc produced in the United States, and her zinc industry is yet in its infancy. She also ranks second in the production of lead, being surpassed by Colorado only. The lead mines located in San Francisco County produce more lead than any other plant in the world, with one exception. This plant will be represented in the exhibit by a handsome model in brass and cherry, costing about $3000. Numerous magnificent specimens of disseminated ore from this mine will also be exhibited. The zinc region lies principally in southwest Missouri and the zinc industry has had greater development in Jasper County than elsewhere. Enormous quantities of lead have also been produced in this county, and a specimen of pure galena weighing 6500 pounds will be shown. Specimens of zinc ore, or 'jack' as it is commonly called, weighing 2500 pounds will also be an attractive feature.

"Numerous other large specimens of great interest to the mineralogist will be among the collection. No better criterion of the relative importance of the mineral industries of Missouri could be given than the favor shown the State in the allotment of space. Two main aisles, one running east and west and one north and south through the Mining Building, intersect at the center, making the four corners at this intersection especially desirable. To Missouri was allotted one of these choice corners, and the installation of her mineral exhibits is now well under way. The facade of this exhibit along the aisle lines is composed of granite, Roman brick and terra-cotta products of the State. These in turn are surmounted by a cornice painted to conform in color with the terra-cotta composing the pilasters and coping. The general effect is most impressive and has already elicited favorable comment from all who have seen it. Numerous ornamental figures relieve what was otherwise monotonous and severe in the pilasters composing the colonnade of this exhibit. The cases in which the specimens will be exhibited are all of quarter-sawed oak of handsome design, with polished finish. In addition to the lead and zinc an immense number of minerals, stones, clays, shales, slates and coals will be exhibited. An interesting feature of this exhibit will be a large topographical map of the State giving the distribution of the more important minerals, also the elevation above the sea level and the general lay of the country. There will be two small models made with especial view to exhibiting two prevailing types of topography, one of the hilly portion of the State and the other of a rich prairie locality in the State underlaid by coal. The commission has endeavored, by means of specimens, models and maps, to give to the visitor a complete epitome of the mineral resources of the State. Other models showing the mode of the occurrence of the ore in the different geological formations of the State have also been provided, so that nothing has been left undone to facilitate investigation into the mineral resources of Missouri."

The entire administrative work involved in making this collection of exhibits has been done by Mr. Gwynn. In selecting men to do the work he regarded the special training and fitness of the in-

dividual, backed up by a natural love of a particular pursuit. The work progressed smoothly and successfully, as the showing of the State demonstrates. In the department of minerals Dr. E. O. Hovey was made superintendent, and under his general direction the mineral collection has been made. James A. Reeves of Joplin, a practical miner of large experience, was placed in charge of the lead and zinc collections. Professor Arthur Winslow, State Geologist, was given the general supervision of the collection, so far as its scope and intent are concerned, and he and his excellent corps of assistants rendered not only valuable but earnest and enthusiastic aid in securing specimens of every valuable mineral product in the State.

British Catalogue Ready.

Sir Henry Wood, representative of the British Royal Commission, has presented to Chief Walker Fearn of the foreign affairs department a copy of the official catalogue of the British section at the World's Fair.

The volume is reported to be very complete, and comprises 544 pages of actual catalogue matter, divided under department heads with appendices, and the whole work supplemented with a complete alphabetical index. The departments of the exposition are treated in the order followed in the official classification and each department is introduced by a preface upon the scope and character of its exhibits written by some eminent man, a specialist in that direction. For instance, that of agriculture is written by Ernest Clarke, a well known authority; horticulture by W. Thistleton Dyer, C.N.G., F.R.S., director of the royal gardens, Kew; mines and mining by C. Le Neve Foster, D.S.C., F.R.S, inspector of mines and professor of mining in the Royal College of Science; transportation exhibits by Sir Douglass Galton, K.C.B., D.C.L., F.R.S.; the preface of fine arts, painting, architecture and decoration is written by J. E. Hodgson, R.A., professor of painting to the Royal Academy of Arts. The introductions to other departments are written by men equally eminent in their special directions. The list of members of the royal commission in the book is headed by H. R. H. the Prince of Wales, K. G., as president of the Society of Arts. A general plan of the grounds and buildings is included in the book.

Sending Exhibits Unmarked.

Master of Transportation Holcomb is getting in deep water at Jackson Park. He has a small railroad there on which he is endeavoring to handle expeditiously the cars of exhibits which are daily arriving. Mr. Holcomb's railroad is not large enough for the occasion, and a blockade is seriously threatened. It will come about not so much on account of the facilities at Jackson Park as because of the heedlessness of American exhibitors, who have exercised no care in billing their goods. Specific instructions were sent out months ago with blanks stating that each exhibitor should indicate on the blank just where the exhibits were to be installed, and then nail the card on the side of the car. If these instructions had been followed there would have been no difficulty in hauling the car to the proper building when it reached the park. As it is there is no indication on hundreds of cars as to their destination in the grounds. It requires hours at a time to go to the records and discover merely by the number of the car where it belongs. The result is that they are mixed up in the yards, and any degree of facility in handling them is out of the question.

Foreign exhibitors obeyed instructions and have greatly aided the work of installation. There has been no difficulty in placing their shipments. Mr. Holcomb is beginning to feel the seriousness of the situation, especially when he goes down into the freight yards in the southwest corner of the grounds and discovers almost every track covered with long trains. But little switching can be done during the day. All this work has to be performed at night, and the cars left standing throughout the day to be unloaded at the several buildings. Every day the number of cars received increases, and a few more pile up in the yard.

At the Centennial there were about 5000 carloads of exhibits. It has been estimated there will be at least 10,000 at Chicago. Of this expected number but little over 2000 have been received. If the remaining 8000 should come in regularly there would be an average of over 300 cars each day for the remaining time before the opening May 1. Thus far the highest number received has been about 200, and if difficulty is experienced now it is easy to predict what will happen toward the end of the month.

The Bethlehem Iron Company's Exhibit.

Lieut. W. H. Jaques is now in Chicago supervising the installation of the exhibit of the Bethlehem Iron Company of South Bethlehem, Pa., which comprises the following articles:

	Dimensions.												Approximate weights.	
	Length.		Breadth.		Hight.		Thickness.	Diameter. Outside		Diameter. Inside			Pounds	Tons. *

Specimen German Parlor Car.

One of the interesting foreign exhibits in Transportation Hall is a parlor car such as German railroads use, built by Van Der Zypen & Charlier of Cologne. This car was shipped in pieces filling 20 large boxes, each piece finished so that the whole can be put together without a hammer. The body of the car is 30 feet long, 10 feet wide, and is built mostly of steel. The lower half of each side is a solid sheet of steel 30 feet long, 3 feet broad, and ⅛ inch thick. On the side plates rest the window frames made of wood, covered with sheet iron. The cross bars of the running gear are made of pressed steel. The interior of the car is finished in solid brass of fanciful design, buff silk and blue velvet. The top, made of sheet steel, is oval in shape and tastefully decorated. The platform at either end is surrounded by beautifully wrought railings of iron. The interior arrangement is similar to that of the day coaches found on American railroads. The seats are arranged along either side with an aisle in the center. After it has served its misson at the exposition this car will be taken back to Germany and put in service on a branch of the Prussian State railway between Wiesbaden and Langenaschwalbach.

Relic of Early Railroading Days.

Another interesting relic of early railroading in this country has just been forwarded to the Transportation Department of the exposition by the Illinois Central Company. It is a locomotive of English build brought to the United States in 1836. For several years it was operated on the Natchez & Hamburg road, now part of the Illinois Central system. In 1868 it was taken to Vicksburg, but

shortly after ran into a river, where it was buried until 1870, when the superintendent of the road had it dug out and put in service again. Although largely out of date and at least a full generation behind the times, it was kept in use on a small branch road down in Mississippi up to three years ago. The engine is a curious looking machine and will be an interesting attraction. When first put in service it ran on strips of iron bolted to wooden rails laid lengthwise. A section of the old track 30 feet long will also be shown.

Foreign Exhibits.

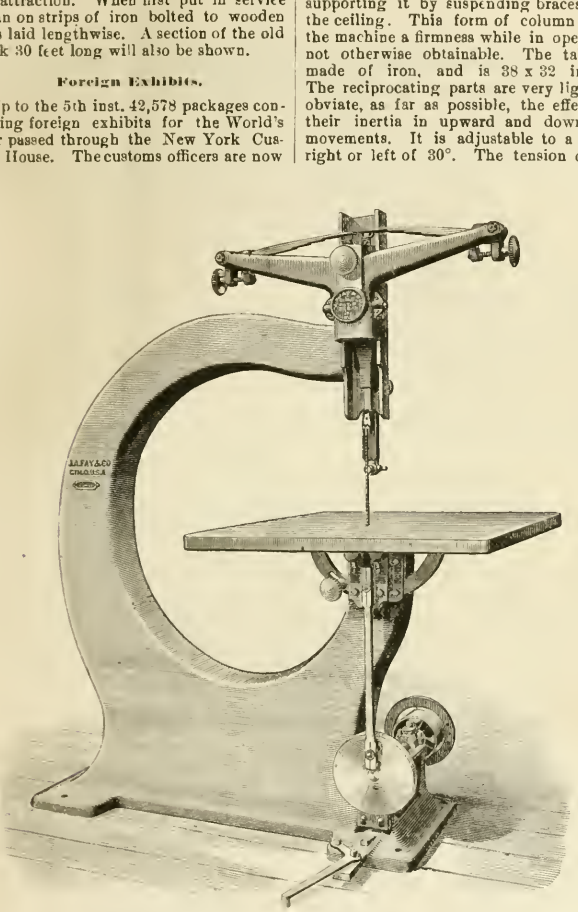
Up to the 5th inst. 42,578 packages containing foreign exhibits for the World's Fair passed through the New York Custom House. The customs officers are now looking after between 1400 and 1500 packages which were shipped from Bremen. They belong to the Italian Government, the bulk of whose exhibits have been sent on a national vessel to Portland, Maine. The packages in New York will be shipped to Portland in charge of a special officer, and will be taken to Chicago with the main lot. Two hundred British soldiers, representing every branch of the English military service, and the crack representatives of some of the most famous regiments of the British army, arrived from London on the 5th by the steamer "Massachusetts."

The Great Ferris Wheel.

The axle for the Ferris big wheel on the Midway Plaisance was put in place on the 6th inst. It was hoisted 150 feet from the ground, where it now rests on the supporting columns. The casting weighs 56 tons. When the arms are built out around it and the cars attached to their ends the turning of the wheel will lift passengers to a hight of 270 feet.

The Fay & Egan Fret Scroll Saw.

The fret scroll saw here illustrated is designed for use in pattern shops, and for all external and internal curve sawing. The column is made in the cored form, has a broad base, and extends over the table to support the entire strain attachment, thereby obviating the necessity of supporting it by suspending braces from the ceiling. This form of column gives the machine a firmness while in operation not otherwise obtainable. The table is made of iron, and is 38 x 32 inches. The reciprocating parts are very light, to obviate, as far as possible, the effects of their inertia in upward and downward movements. It is adjustable to a bevel right or left of 30°. The tension of the



THE FAY & EGAN FRET SCROLL SAW.

machine is flexible, the upper end of the saw being attached to a strap, which at its upper end is connected with a segment pulley having an eccentric roller, connecting with two steel leaf springs. This combination produces, in operating, an almost uniform tension throughout all parts of the stroke of the saw, the eccentricity of the roller being so adjusted that, as the saw is drawn in its downward stroke, the lessening flexibility of the springs is compensated for by the shortening leverage of the eccentric roller. The springs are attached to a sliding cross frame, adjustable to and from the table for different lengths of saws. It has an efficient brake and shipper attached for starting and stopping. The cross head is made adjustable, and can be quickly set to any desired rake.

This machine is built by the J. A. Fay & Egan Co. of Cincinnati, Ohio.

The consumption of coal in London is calculated at 15,000,000 tons yearly.

Subterranean Temperatures.

In answer to a question as to the method of taking temperatures of rocks at different depths in mines, the *Mining and Scientific Press* of San Francisco gives a description of the *modus operandi* adopted by Charles Forman in determining the temperatures in the Forman shaft some ten years ago. The temperatures were taken from the surface to a depth of 2300 feet. They were ascertained by drilling holes not less than 3 feet deep into the rock and inserting into the hole a Negretti and Zambra slow-acting thermometer of the pattern adopted by the Underground Temperature Committee of the British Association and standardized at Kew. These holes were closed with clay and the thermometers were left in for 12 hours, not less than three holes being tried at each point. The following are the depths in feet and the temperatures in degrees Fahrenheit:

Feet.	Deg.	Feet.	Deg.
100	50½	1300	91½
200	55	1400	96½
300	62	1500	101
400	60	1600	103
500	68	1700	104½
600	71½	1800	105½
700	74¾	1900	106
800	76¼	2000	111
900	75	2100	119½
1000	81½	2200	116
1100	84	2300	121
1200	89¼		

It may be stated that more accurate results might have been attained had the holes been filled with water, the thermometers put within a foot of the bottom, the holes then plugged and the thermometers left for 12 hours. In the dry state the average heat of the rock is not so well ascertained as it is when equalized by the water. However, the results would not differ very greatly. Of course, higher temperatures than this are experienced in certain drifts and close places in a deep mine, but it was the actual temperature of the rocks which was desired. In the record quoted, no mention is made of the varying characters of the rock itself.

From an engineering exchange we learn that a process of recovering tin from clippings of tinned iron has been devised by M. Lambotte of Brussels. The clippings are introduced into a vertical cylindrical furnace, which is surrounded by a spiral. Air charged with chlorine gas passes through the spiral, where it is heated by the heat of chemical action going on within the furnace and, entering the furnace below, passes through the clippings. The tin is attacked and stannic chloride is formed, which volatilizes and is subsequently collected upon condensing surfaces moistened with a solution of the same chloride. The iron is not attacked, and when entirely cleaned from tin is removed from below and again used. At the Molenbeck works of M. Lamotte some 2,500,000 pounds of tin clippings are annually treated by this process.

"Outdoors" is the title of a refreshing little book published by the Pope Mfg. Company, Boston, in the interest of the Columbia Bicycle. The covers are in ten water colors, and inside are articles on Lawn Tennis, by F. A. Kellogg; Yachting, by George A. Stewart, successor to Edwin Burgess; Cycling, by Julian Hawthorne; Football, by Walter Camp; Baseball, by J. C. Morse; Horsemanship, by H. C. Merwin; Rowing, by Benjamin Cartis; Canoeing, by C. Bowyer Vaux; a collection of authoritative articles on healthful outdoor pleasures, illustrated by Copeland, Beals, Gallagher, Young and Shute.

THE TIN SHOP.

Patterns for an Oil Tank.

From R. H. W., *New Albany, Ind.*—I inclose the drawings of an oil tank that has caused me considerable trouble in laying out. The problem will probably interest many of the readers of *The Metal Worker*. The article is an oil tank, to be made in six pieces, including the sides.

Referring to Fig. 1, I begin to lay it out from N and O and bend the sheet at A' and B'. This brings me to K and K', which is all right. I next begin at K and K' and bend the sheet at G' and H. After bending at G' and H', the sheet reaches M on the left side, and much further up on the other. Then I begin at N and O and bend the sheet at C and D, F and E reaching P on the left side, then put in a piece between P and M. It is evident the problem of laying out comes before the bending. How should the various parts be described?

Answer.—For convenience, the parts of the tank in our correspondent's sketch have been numbered. No. 1 is the large side, No. 2 the small side, No. 3 the front, and No. 4 the bottom of the tank.

In Fig. 2 is shown the side and front elevation, also the plan of bottom. The various points are lettered and the sides and end numbered to correspond with Fig. 1. The plan is also drawn in line, and below the elevation. The side elevation shows the article as it would appear with the smaller of the two sides to the front. This enables us to show the top No. 5 and top No. 6 in elevation, two important features that are lacking in our correspondent's drawing. In Fig. 1 the shapes or patterns of the two sides, end and bottom are shown. If the tank was to be made from heavy iron, and the joints made at the corners, all that would be required to complete the patterns would be the patterns for tops Nos. 5 and 6. In Fig. 6 is presented a view of the finished article as it would appear when viewed with the side No. 2 to the front. This figure will help the reader in understanding the shape of the article, which shape is rather vaguely indicated by the parts shown in Fig 2. The reader is also at liberty to study the plan and elevations in Fig. 2, and determine what assistance is rendered when the various parts are drawn in proper relation to each other.

Supposing the article to be made in six pieces, and with the seams at the corners, the shapes shown in Figs. 1 and 2 are all that are required for the patterns of the two sides, front and bottom.

We will next proceed to develop the two remaining patterns for tops Nos. 5 and 6. For the pattern of top No. 5, using the drawings in Fig. 2 for the purpose, proceed as follows: Draw any line, as Qa Rb in Fig. 3, in length equal to C' D' of front elevation, which gives us the slant hight. This line is shown in plan by $a'b'$, and in side elevation by $c\ d$. From the point Qa of pattern erect the perpendicular $Qa\ Sf$, in length equal to $c\ f$ of side elevation, or $a'\ f'$ of plan. From the point Rb of pattern erect the perpendicular Rb Te, in length equal to $d\ e$ of side elevation, or $b'\ e'$ of plan. Draw the line Sf Te, which completes the pattern for top No. 5.

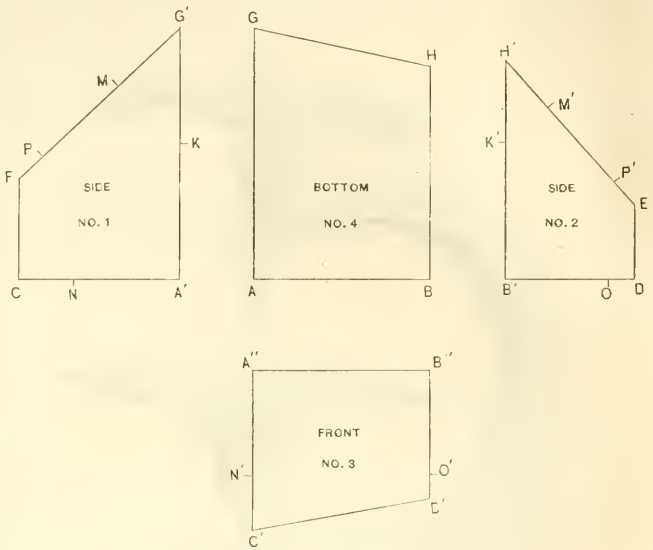


Fig. 1.—Sketches Submitted by "R. H. W."

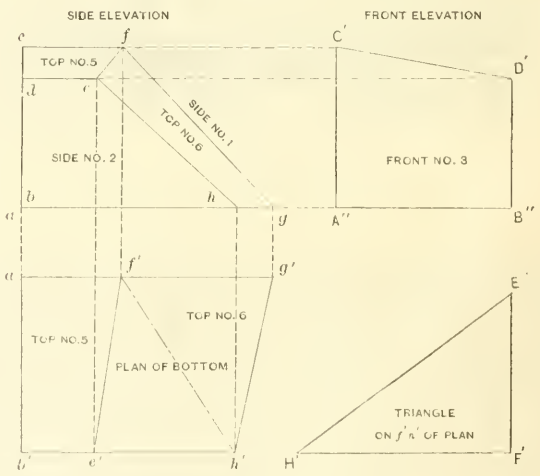

Fig. 2.—Side and Front Elevations, also Triangle on f' h' of Plan.

PATTERN FOR AN OIL TANK.

As the sides Nos. 1 and 2 in the side elevation are the true patterns of the respective sides, it must be evident that the lines $f\ g$ and $e\ h$ give the correct length

for the two sides of the pattern for top No. 6. As we have just obtained the pattern for top No. 5, the line Sf Te of the pattern just obtained must be of the same length as the left side of top No. 6, as shown in plan by line $e' f'$, or in side elevation by line $e f$. Then for the pattern of top No. 6 draw the line Uf Ve, in length equal to the top line in Fig. 3. The next step is to obtain the location of points Wg or Xh of pattern. We will obtain the location of point Xh. To do this draw the line H' F' in Fig. 2, in length equal to the broken line $f' h'$ of plan. From the point F' erect the perpendicular F' F'', equal to the hight of article, as indicated by $a c$ of side elevation. Connect H' F'', which gives the distance from point h' in the material. If the work was to be done in a shop that was not provided with a suitable brake for bending heavy iron, supposing the article was to be made from such material, it might be found convenient to cut out each piece shown separately, bend the edges for lap over a block of hard wood or iron and thus have the seams or joints come at the corners.

As no opening is either shown or mentioned, it is supposed the article is to be either double seamed or riveted together. Supposing the various pieces are to be joined by riveting, allowance must be made for the last piece put in, so the riveting can be done from the outside and thus avoid the danger of riveting the helper inside.

tom, front, and the two tops, the various parts being placed together as our correspondent attempted to do, the intention evidently being to have the article so constructed that the bending will be mostly done on the corners, the metal being joined as indicated by the dotted lines. As a similar system of lettering has been employed in Figs. 1 and 5, the reader will have little difficulty in following the description.

Referring to Fig. 1, our correspondent commences at N O, making the first bend at A' B', A'' B'' of Fig. 5. For some reason, it is decided to have a seam at K K'. The next bend is located at K K', K' Kk of pattern. At this stage of the proceedings the correspondent remarks

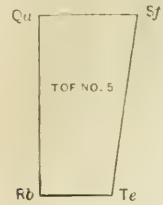

Fig. 3.—Pottern of Top No. 5.

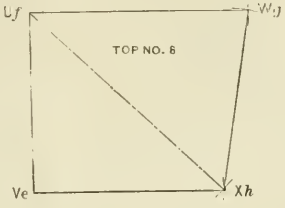

Fig. 4.—Pattern of Top No. 6.

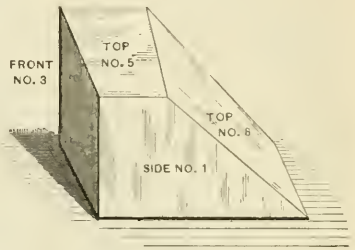

Fig. 6.—The Finished Article.

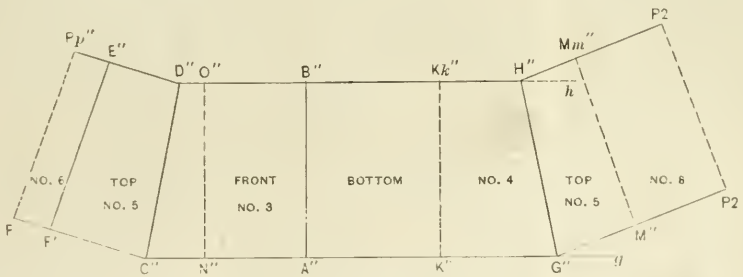

Fig. 5.—Pattern of Bottom, Front and Tops.

PATTERN FOR AN OIL TANK.

plan to point f of elevation, as if measured on the finished article. With H' F'' of triangle as radius and Uf of pattern as center strike a small arc, as shown. With point Ve of pattern as center and Sf Te of Fig. 3 as radius strike a small arc, thus establishing the point Xh of pattern. Draw the line Ve Xh. With Uf of pattern as center and $f g$ of side elevation as radius strike a small arc, which intersect with one struck from Xh of pattern as center and $h' g'$ of plan as radius, thus establishing the point Wg of pattern. Draw the lines Uf Wg and Wg Xh, which completes the pattern of top No. 6.

We have now obtained the patterns for each of the six sides, and, supposing the patterns to have been cut out of some convenient material, as cardboard, it would be easy to "lay out" the pattern on the sheet iron in any way desired or as might be considered the most saving of

The front, sides and top No. 6 could be cut an inch wider at the bottom and an allowance of an inch made about the bottom. This would make the article 1 inch higher than shown in the elevation, but the inside would be of the desired dimensions. By this means the bottom could be riveted in without trouble. Inch boards could be placed under the bottom to take off all strain from the metal when the article was full of oil.

If the article was to be made by double seaming the joints at the corners, the bottom, front and two tops could be cut 1 inch wider, and a suitable allowance made about the two ends so a "double" edge turned, so when the edges of the ends were pounded down the soldering could be done from the outside. If desired, the article could be made in any convenient manner and the front put in last.

In Fig. 5 is shown the pattern of bot-

"After bending at G' and H', the sheet reaches M on the left side, and much further up on the other." In Fig. 5 the shape of No. 4 is clearly shown, as is that of No. 6. The continuation of the sheet is indicated by $h g$, and it is quite evident that a "straight" sheet of iron is not adapted to reaching the points of pattern indicated by M'' Mm''.

Starting again from N and O of Fig. 1, or N'' O'' of pattern, points N'' O'' are reached with safety, but disaster attends the turning of the corner C'' D'' if a straight sheet is used, as the sheet is not inclined to reach the points F'' E''.

The coal area of New South Wales, Australia, is computed to be about 36,000 square miles. The available coal contained in seams more than 2½ feet thick is 78,198,000,000 tons, or about the same quantity as there is in the coal fields of Great Britain. The beds are stated to be so situated as to be readily accessible without deep mining.

The Foundrymen's Association.

The regular monthly meeting of the Foundrymen's Association was held at the Manufacturers' Club, in Philadelphia, on Wednesday evening, the 5th inst., with a large attendance of the members.

In the absence of the president, the chair was taken by P. D. Wanner of the Mellert Foundry & Machine Company of Reading, Pa.

The Executive Committee, Railways and Freight and Special Committees reported progress.

Four new firms were elected to membership in the association.

Reports from the different sections of the Price Committee were received and discussed. While reporting for his section of the committee, P. D. Wanner said that he thought prices had somewhat improved since last meeting owing to the dry weather experienced during last year. He had noticed in past years that such a condition had a great tendency to stimulate the cast iron pipe trades owing to the building of water works and the bringing in of additional streams, necessitating many castings and supplies. Such was the case last season and again this season. A good many of the pipe foundries East and West would be fully employed until probably the middle of the year, and, perhaps, until fall. He thought that even if the shops had only low-priced work a better feeling would be created, especially among those whose shops were not quite as well filled and others who had room to fill in at quite an advance in price. Beyond that he did not think he could promise anything.

The capacity was, of course, much beyond the demand. He believed that pipe foundries all over the country would during the year be pretty well supplied with work, and at much better prices. Through the present month prices had, he stated, ranged from $1.05 to $1.17, according to the different sizes. Special castings had held their own at about 2½ cents. Some had gone below that price, but there had been no reason at any time to make the cuts. Many would cut for fear some one else might take an order which they considered they ought to have themselves. The lowest price on general castings he had heard reported under this heading was for a letting on lamp posts in the city of New York. There was a letting in that city a few weeks ago for 1200 posts, made in three pieces and weighing about 350 pounds These posts were taken at $1.65. This price he thought was a record breaker. He believed the lowest price at which they had previously been supplied was $1.79. There were four competitors on this letting. One bid was $1.65, two others $1.90 and the remaining one $2 23.

Howard Evans, the secretary, reported a contract just awarded to a concern in Trenton for columns for some works in Boston at a fair price—higher than $1.65. He was not informed as to the terms of delivery of the columns, but the contract called for 250 tons.

L. B. Whitney of A. Whitney & Sons, manufacturers of car wheels, Philadelphia, reported that only two manufacturers of car wheels were members of this association, hence there was a difficulty in arranging a meeting of this section of trade. He would, however, mention that his firm were invited, among others, to make a bid on 2400 Pennsylvania standard wheels. They duly quoted a price, but afterward learned that the wheels could be bought at from 50 cents to 75 cents per wheel less than the price at which they could offer. Their price was at $7 50. A wheel weighs 500 to 600 pounds, and the freight at 9 cents per 100 pounds and the commission to be paid would make the net price to the party taking the contract $7.10, or less than the iron from which his firm made wheels would cost. As soon as they learned of the offer already made they notified the parties asking for bids that they did not care to bid on business of this kind, as they could not afford to allow their names to appear on castings which could be sold for such a low price. This incident, he thought, proved that there was no necessity for quoting less than at least $7, and with a little of the nerve displayed by many of the members in the association, he had no doubt the contract might have been taken at $7.50. All in the business seemed to be afraid of each other.

E. E. Brown of E. E. Brown & Co. reported progress of the small castings section of the committee.

The subject of forming sections in the association being again up for discussion, P. D. Wanner said that it was apparent that very little had been done thus far. According to the report of the Executive Committee it might be judged that it would be a dangerous step so far as the raising of prices was concerned. On this point he wished to say that he agreed in the main. He thought that it would be dangerous for any persons representing the different specialties of this association to combine with a view to raising prices to an unreasonable extent, although it should be understood that they were not running their respective businesses for the fun of the thing. All were working for something, and the general object was to make money for the bettering of conditions. In the present condition of civilization he considered that advance could only be made by profit in their respective lines, and it was, he thought, quite lawful for them to do so. In any combination formed with the view of running a business, improving conditions, or of bringing themselves into position to make money, they were keeping themselves within the law. It was, he said, only where a combination proposed to take hold of something to the exclusion of every one else that the law would step in and declare it an illegal procedure. It was quite advisable for an association to seek to control prices. He believed that every class of men should form associations to advance their trade, and in doing so might have to advance their prices. He understood this as the idea of the present day and regarded it as a leading feature in business in this and every other country. They were all aware of their weakness and therefore united for strength. In union there was strength, and a combination or association would be strong. He thoroughly believed in the principle and they should to that extent favor the measure and try to get those interested together, although he admitted there would be a great deal of trouble in the effort to do so. Some would not want to come into the arrangement for special reasons of their own. He would recommend that such be left out, but it would be well to get in as many as possible. He had been actively connected with the pipe trade for 15 years or more, and an arrangement had been attempted many times to cover the whole country, and especially the East. Some would come in, others stay out, and as a consequence it always ended in failure. But as he had before stated, he would be willing to stand up with any three, four or five manufacturers in the pipe trade, and adhere to arrangements for an association. There were many things he thought they could do for each other if they would only come together. A common sympathy should exist in regard to orders. What one did not make, another might, and mutual help be beneficial. He thought they should not be discouraged, but go on. It might take some time before all could be brought in, but it was no reason why these sections should not be formed. He had no doubt all discouragements could be overcome. Eventually all would unite, as those who would band together could materially affect those who declined to enter an arrangement, and they would finally wish to come in. He had great faith in the consummation of the arrangement. Very often he had found that those who appeared to be strongest had proved to be the weakest when their business was gone into, and were the first to cry for pardon. Their bravery had been all on the outside.

In regard to the possibility of the pig-iron trade effecting an arrangement for better prices, consumers should not be surprised at any time to find that the pig-iron men had been taking care of themselves in that direction. He certainly should not blame them, and would like to see it. They would probably find that in the South all the pig iron and the furnaces would go into the hands of a few concerns and thus a step toward the control of the whole trade and the command of prices would be made. Such a step would not come unexpected to him, and if the prices were not entirely unreasonable such a course would meet his approval.

The secretary announced that a number of letters had been written to prominent people upon the subject of coke, as the matter had proved of so much interest to the trade, and in response there were representatives that evening among them for the purpose of giving any information required. Many had expressed a desire to hear more on the subject, and particularly as to how coke was manufactured from the beginning; what kind of coal was used; how long it took to turn coal into coke; what kind of water was used in cooling it, and points generally in regard to its manufacture.

Jones Wister of L. & R. Wister & Co., Philadelphia, then made instructive remarks on the subject, supplementing the address delivered by him before the February meeting of the association, embodying a vast amount of information relative to the manufacture of coke and its adaptability to foundry uses. At the close of the address the appreciation of the meeting took the form of a vote of thanks to Mr. Wister.

Mr. Winks of the Davis Coal and Coke Company stated that Mr. Ramsey, the superintendent of his company's West Virginia ovens, had intended to be present and had prepared a paper to read before the meeting. Mr. Ramsey had had a great deal of experience in the manufacture of coke, and it was to be regretted that he had found it impossible to attend.

The chairman invited discussion on the subject of pay days. He considered it an important subject and one which the association would do well to consider at its meetings. He believed wages should be paid once a month only. In paying their hands weekly or fortnightly they were doing more than they ought to do in justice to themselves. He thought that there was no necessity for more than one pay day per month. This course, he claimed, would save a good deal of time and trouble to manufacturers. His company paid their employees every fortnight and experienced a good deal of trouble under that plan. He alluded to the Pennsylvania State law on the subject as ineffective and unconstitutional, inasmuch as it could not be carried out. He thought the subject should be open for discussion at future meetings.

Mr. Lewis of the Waterbury Foundry & Machine Company, Waterbury, Conn., said that he had derived much pleasure and instruction from the meeting. He had been in business 47 years with satisfactory results, but he regretted that it had really come to the point in his section when they could not get a decent living on raw castings. This company were large builders of machinery, and it was from this branch of their business he thought that their profits largely accrued. While he

would desire an advance in prices, he considered it would be very difficult to get co operation, there being so many in the trade. He had not as much confidence as he felt he should like to have in its accomplishment, as he thought every business man recognized that each concern was doing the best it could for its own interest. However much it might respect its neighbors and friends in the trade it would figure on a contract as low as possible and would then go a little lower if it found its neighbors were likely to get the job. While he admitted that it would be very well to get up a friendly and fraternal feeling, he did not think an arrangement could rest upon that. A bond would have to be in some way effected whereby a forfeiture in the event of violation of an agreement would be made. As an instance of the working of the friendly plan he cited the case of a meeting in another section called for the purpose of obtaining an advance in prices where a member, after asking to be excused a moment, in the interval rushed to the telegraph office and wired his customers: "Put in your orders. Prices advance to-morrow." He did not think that human nature varied a great deal in the different latitudes. He believed the best method for effecting an arrangement regarding prices would be the one involving forfeiture for violation.

Floor plates in his section were being made at 1¼ cents per pound, delivered on cars, and the prices of large castings were very low. He considered that the confidences enjoyed at the meetings of this association were productive of much good to its members. He hoped that the details of foundry practice would not be overlooked in their discussions. He felt that he could learn many things concerning the making and positions of cores and the insuring of good sound surfaces.

The chairman stated that at previous meetings of the association much valuable information had been elicited on the subject of foundry details. Core sand was, however, in his opinion, a good subject for discussion, as also foundry facings. He believed there were a number of gentlemen connected with the association who could furnish valuable information on these subjects. A motion was then made that the Executive Committee be asked to arrange addresses to be delivered at the next meeting on "Foundry Facings" and "Core Sand."

The meeting then adjourned.

Ventilation in London Workshops.

The Public Health Department of the London County Council have issued a report of a medical inspection of workshops in some of the most crowded of the poorer metropolitan districts, which proves that the system of ventilation in these shops is of the most elementary kind. "In no instance," says the report in question, "was any artificial means of ventilation seen Such interchange of air as might occur could only be brought about by the 'natural ventilation' afforded by the chimney flue and other openings—windows and doors. A note was made of all windows which were not found shut. In the 114 workshops inspected there were in all only 11 in which open windows were found. One master, on being asked whether the windows were ever open, replied: 'Only in the spring and summer months.' Another master excused the overcrowded condition of his workroom by remarking that when the workpeople felt the air to be close and oppressive he did not allow them to remain in one place, but caused them to 'move about from one part of the room to another.' It appears to be questionable whether any attempt is ever made during the winter months to cause a current of cool fresh air to circulate through some of these workrooms."

Prize Competitions

$25.00.

Prize Competition No. 20.

SUBJECT:

A Reliable System for Securing the Correct Charging of All Goods Sold on Credit.

The adoption of cash sale tickets, cash carriers, cash regiaters, &c., has provided for the strict accounting of cash sales. As credit is almost universally given to a greater or less extent in connection with cash, it is necessary that goods thus sold should not leave the store without being properly charged. The object of this competition is to draw out practical suggestions or descriptions of systems in use whereby the charging of all goods is insured. The subject touches also the following points: How to avoid charging undesirable parties without giving offense, and how to avoid charging small amounts.

This competition will remain open until May 6, 1893.

Those intending to compete are reminded that it will not be necessary to write long essays, but that comparatively brief and business-like answers will be favorably regarded as meeting the purpose for which these competitions are announced.

The following prizes will be awarded:

First prize	$12.50
Second prize	7.50
Third prize	5.00

The prizes will be awarded for answers which in the judgment of the committee of award are most suitable for publication and of the most general interest. We reserve the privilege of extending the time on any competition in case the contributions received are not of sufficient number or merit for the committee to award prizes. These competitions are open to every one, and it is hoped that there will be a general response from business men. We shall have the privilege of publishing any or all of the contributions received.

Replies are to be received not later than May 6, 1893. They should be addressed as follows:

DAVID WILLIAMS,
96–102 *Reade street,*
New York.
Prize Competition No. 20.

The committee to whom the contributions in Prize Competition No. 6 were referred have awarded the prizes as follows:

First Prize of $50 to FERDINAND TUSCH, Brooklyn, N. Y.

Second Prize of $25 to JAMES D. RICHARDS, Covington, Ky.

Third Prize of $15 to M. STRANSKY, New York, N. Y.

Fourth Prize of $10 to F. F. GILMORE, Louisville, Ky.

Other Competitions which have closed are now in the hands of the Committees of Award, who are giving careful attention to the claims of the different contributions. From the number of these and the evident merit of not a few of them, we are assured that a great deal of valuable information and suggestion will be put at the disposal of the trade.

The Weekly Prize Competitions noted below are now before our readers and remain open until the dates named:

No. 17. Closing April 15.
How Merchants Should Treat Traveling Salesmen.

No. 18. Closing April 22.
The Extent to Which Merchants Should Devote Their Attention to Outside Interests.

No. 19. Closing April 29.
Electrical Goods as a part of a Hardware Stock.

No. 20. Closing May 6.
A Reliable System for Securing the Correct Charging of All Goods Sold on Credit.

Another subject will be announced in our next issue.

In responding to the toast of "The Corporation of Salford," at a dinner of the Manchester Association of Engineers, recently given in Manchester, England, Alderman Bailey of Salford, in referring to the value of technical education in connection with the engineering industry, made some pointed remarks in the matter of American competition in the line of mechanical products, and the best method of meeting it. "The wars," said the alderman, "which at one time were waged between the princes and potentates of different countries were now things of the past; the wars which were now being waged were between the workmen of one country and the workmen of another country, and he urged that his hearers should carefully study the imports to see where the workmen of other countries were beating them. He was convinced that there were a number of articles in which they were allowing their American and Continental rivals to beat them, which they could make not only just as cheaply, but much better, at home. He had been singularly successful in preventing many German and American goods coming into the country; and if they would only bestir themselves, there were a great many other articles which were being supplied from abroad, which they could make themselves at a right down good profit. The English were, however, very much behindhand in one thing—the foreigner knew how to sell better than they did. The Americans could bring over their lathes to England, and get higher prices than were being paid there to English makers. This was a thing that English manufacturers ought to be ashamed of; it was simply a question of the foreigners being better salesmen than they were. Their competitors had united the Anglo-Saxon enterprise with the German technical knowledge, and produced so much better salesmen that frequently they were able to sell goods in England of inferior quality and at a higher price than they could be produced in that country. He would urge that they should take up technical education in a thoroughly efficient manner; and with the natural advantages possessed by Great Britain, she ought, he believed, to be able to defy the world."

In announcing the prize winners in Prize Competition No. 5, in our last issue, it was stated that the first prize had been awarded to H. S. Drummond of Newark, N. J. Mr. Drummond's middle initial is, however, G. and not S as printed.

The New York Trade School.

Closing Exercises for the 1892-1893 Season.

Notwithstanding the inclemency of the weather a large and interested company of students and visitors assembled on Friday evening, April 7, at the New York Trade School, First avenue and Sixty-seventh street, New York, to witness the result of the work of the classes during the season just closed and the presentation of certificates to the graduates of the 1892-93 term. Soon after 7 p.m. students and their friends, together with invited guests, began to arrive. The time until 8 o'clock was spent in the inspection of the work of the students, which was displayed in the different classrooms, each collection or piece of work being duly labeled with the name of its author.

The specimens of handicraft shown reflected the greatest credit upon the instructors in the various trades, as well as bore testimony to the diligence and application of the learners who in a short course of three months could attain such proficiency. The exhibit of plumbing work was exceptionally extensive and good, calling forth many expressions of approval from practical plumbers, several of whom were present as guests. A specially interesting feature of the display was the exhibit of trade school work in all its branches which is about to be forwarded to the Columbian Exposition at Chicago.

CLOSING EXERCISES.

Shortly after eight o'clock the meeting was called to order in the Bricklaying School, which had been fitted up for the occasion so as to form a most effective auditorium. At one end of the room the platform, draped at the back and canopied with blue silk, fringed with gold, and decorated with national flags, accommodated the speakers of the evening, members of the committees and some invited guests and friends of the school, including several ladies. The body of the hall was brilliantly illuminated and decorated with flags and patriotic emblems. It was occupied by the graduated students, seated under banners bearing the names of the different classes, the posts of honor being given to the day and evening plumbing classes, which together almost outnumbered all the remainder.

CHAIRMAN'S OPENING REMARKS.

In opening the proceedings of the evening, the chairman, William E. Dodge, made feeling allusion to the enforced absence from the closing exercises, for the first time in the history of the school, of the beloved and honored founder, Colonel Richard T. Auchmuty, who during the long winter months had been an intense sufferer and who had recently been obliged to submit to a critical operation, from which, he was thankful to be able to say, there was every hope that their friend and benefactor would before long recover, as he was now steadily gaining strength. He was glad to assure his hearers that even in the time of his greatest weakness and sufferings the Colonel had maintained the absorbing interest which he had always felt in this, the great work of his life. Continuing, Mr. Dodge said that this was a special epoch in the history of their institution, because for the first time the school stood in the dignity and position of a workman's college. It had been incorporated as such under the laws of the State; trustees had been appointed, and the entire institution had been placed on a solid and business footing. The buildings and the lot on which they stand, as well as a large sum of money, had been absolutely made over to the schools by the generosity of Mrs. Auchmuty, who fully shares her husband's interest in the school. With these generous donations and the noble gift of Mr. J. Pierpont Morgan, amounting to $500,000, they stood there that night owning property worth over one million, free from all incumbrances and ready for much useful work in the future. (Prolonged cheers.)

The chairman then presented Guy Culgin, president of the General Society of Mechanics and Tradesmen, who addressed to the students some earnest words of counsel and encouragement, recommending to them particularly the qualities of honesty and self help, which he himself had found in a business experience of over 40 years to be the only real means of insuring a lasting success.

At the close of Mr. Culgin's remarks, the chairman said: "I wonder what we should do, in the modern civilization of our cities, without plumbers. They have been called expensive luxuries; but people find they can afford to pay for good work; and it is one of the objects of this school to elevate the standard of plumbing work. I will now introduce Mr. Henry G. Gabay, president of the Master Plumbers' Association, who has come here to address you." Mr. Gabay spoke as follows:

MR. GABAY'S ADDRESS.

There is an old maxim—"Brevity is the soul of wit." Be as brief, then, in all matters as is consistent with a strict interpretation of your subject, especially in a speech. Some persons I have heard speak put me in mind of the wife of a friend who had been married but three weeks. While walking down the avenue the gentleman in question met an old school chum, who, seeing the look of despair on his face, said: "Why, Jones, what is the matter? You look very unhappy—look as if you had lost every friend in the world." Jones replied, "Oh! yes; I am the most miserable man in existence; very unhappy indeed." "Why?" was the reply. "You unhappy; you who have just been married! You should be one of the happiest men on the face of the earth. Come, now, tell me what troubles you." "Well," Jones replied, "my wife can't sing." "Can't sing!" said the other. "Why, that should add tenfold to your happiness. Come, that won't do." "Well," said Jones, "the great trouble is, she thinks she can."

Now, boys, I will just say a few words to you on the subject of "grit." Impress that word on your mind and live it in your life. I don't mean cheek. Some folks mistake cheek for grit. I have known some who seemed all cheek. If one side was not enough they were ready to turn the other also.

The young man who possesses "grit" will not be daunted by difficulties or yield up the fight at the first defeat. He may be crestfallen, but will spring back and grapple with the obstacle. He won't sit down and say, "Well, this is the way of the world and I may as well make the best of it." Making the best of it, in that way, means, stifling every ambition, sinking down into the lowest plane of life. That class of individuals can always be seen during the summer—especially in the country—at any railroad station, sitting on freight boxes, whittling a stick aimlessly, satisfied if they can get a plug of poor tobacco. In winter they hang around the village storekeeper's stove, hands in their pockets—Micawber fashion—doing nothing but "waiting for something to turn up." Nothing of any value to them will ever "turn up" in their lifetime. They will turn up themselves sooner, and over their remains might well be placed this epitaph—

"At last he's dead, and here he lies;
And now his soul at "aise" is,
With the end of his nose and the tips of his toes,
"Turned up" to the roots of the daisies.

Then have energy, self reliance, courage, determination. Success and greatness were never won without them. Don't have the false idea that success in life hinges upon what fools call "good luck." A man who claims to be unlucky is guilty of indolence, or carelessness, or else has not the clear judgment which must be cultivated and is so essential in the affairs of life. Every man makes his own luck, and the young man who seeks to throw upon "chance" the burden of his mistakes and failures is a miserable coward.

"Grit," then is what you all must have in order to succeed in this life. It is the one great and essential factor in national growth and development. The difference between the material and political conditions of peoples may be traced in a large degree to the presence or absence of this quality.

The condition of the masses in Ireland was once expressed by an emigrant, who when asked 50 cents for a bushel of potatoes cried, "Faith and I could get a bushel in ould Oireland for fourpence."

"Why did'nt you stay in Ireland an I get them?" said the vender.

"Begorra," said Pat, "but Oi could'nt get the fourpence."

You are now graduating from this school. Every one here, no doubt, has felt that the trade he has selected is the one he desires, has a taste for and is best fitted for. But, alas, how many are mistaken and have planted themselves in a desert, so to speak, only finding it out when it is too late. I trust none of you have mistaken mere liking for real talent. Sidney Smith once said, "Be what nature intended you for and you will succeed; be anything else, and you will be ten thousand times worse than nothing."

Now, having selected your trade, do not be in a hurry to change it. Remember, "A rolling stone gathers no moss." Neither would I despise it. There is no discredit in being a tinker, but there is in being a bad one.

Work diligently; be, above all, modest and humble; and, when you find yourself excelling others, then compare what you have done with nature itself, or with the ideal of your own mind, and you will be secured by the contrast which will be apparent against the effects of pride or presumption.

A word in regard to the founder of this institution, Col. R. T. Auchmuty.

Beginning in a small way with a few students, under his persevering energy and "grit," and the resolution to build up a lasting institution in this city, it has grown and has continued to grow year by year

until it's success is no longer a question, and it is now liberally endowed by one of our prominent men. I trust other philanthropic citizens will follow Mr. J. Pierpont Morgan and continue to further endow it until this great and grand institution can further extend its usefulness and be at the same time entirely self supporting. Then can the Colonel look with pride on the work of his life and feel that he has not lived in vain.

I am sorry he is not here with us this evening; we all know how glad he would be to be present, and I am positive that it is the heartfelt wish and prayer of all that his recovery will be speedy and lasting, and that he may be spared to us for many, many years to come.

I will not detain you longer. The quality I have commended to you will stand you in good stead in the work that lies before you. By it you can overcome any ordinary opposition that may be in your path. Make up your mind that nothing shall daunt you, no difficulty turn you aside from an honorable purpose. If irremovable obstacles be in your way march over them.

"What would you say, sir," said a man to George Stevenson, the famous originator of the iron horse, when the first passenger railroad was being laid—"what would you say if a cow should get on the rails when the train was coming?" "Weel," said the great mechanic, "I should say it would be vera bad for the coo." Boys, you must "make it bad for the coo."

Thomas Fowell Buxton said: "The longer I live the more I am certain that the great difference between men, between the feeble and the powerful, the great and the insignificant, is energy, invincible determination, a purpose well fixed, and then death or victory."

It is very well for genius to light up the path of life, but it must be "grit" that carries a man successfully over the ruts, mounds and hilltops in that pathway. Remember—

"The heights by great men reached and kept,
Were not attained by sudden flight,
But they, while their companions slept,
Were toiling upward in the night."

Mr. Gabay was followed by Theodore C. Johansmeyer, who addressed his remarks principally to the painting and decorating classes.

PRESENTATION OF DIPLOMAS.

The next event on the programme was the presentation of certificates. Those for the day plumbing class were presented by Edward Murphy of the School Committee, and those for the evening classes by James Muir. The name of each recipient was read aloud as the presentation was made by Henry Brill, secretary of the school.

The following are the names of the members of the day plumbing class who received their diplomas on the occasion:

DAY PLUMBING CLASS.

Adamson, George D., St. Paul, Minn.
Babcock, Charles A., Los Angeles, Cal.
Bauer, George E., Crotona Place, N. Y.
Baumann, E. G., Mount Vernon, N. Y.
Beardsley, Charles E., Dunkirk, N. Y.
Bertine, Harry D., Mt. Vernon, N. Y.
Clements, Hezekiah M., Liberty, N. Y.
Cochrane, Thomas S. Jr., New York City.
Crowley, Edward J., Ansonia, Conn.
Demarest, John H., Hackensack, N. J.
Denise, John V., Freehold, N. J.
Dibble, Benton R., New Britain, Conn.
Dimond, Irving G., Penacook, N. H.
Donovan, Dennis F., Bayonne, N. J.
Doscher, B. G., Charleston, S. C.
Drake, Frank, Clinton, Iowa.
Dutcher, Ora D., Middlesex, N. Y.
Eckhardt, H. C. P., Bethlehem, Pa.
Fairchild, H. A., Riverside, Cal.
Feeny, Charles W., Paterson, N. J.
Fellows, James D., Belvidere, Ill.
Fisher, Chas. G., Catskill, N. Y.
Fox, John, New Britain, Conn.
Fox, William H., Eau Claire, Wis.
Frehsee, William B., Lockport, N. Y.
Griffith, William H., Chicago, Ill.
Gutfleisch, Albert A., Lancaster, Pa.
Hamilton, Claflin E., Hillsborough, N. H.
Hann, William, Lyons, Iowa.
Hauser, Frank J., New York City.
Heimann, August, New Haven, Conn.
Herrick, Frederick W., Beverly, Mass.
Herring, George D., Yonkers, N. Y.
Higgins, Frank H., Ithaca, N. Y.
Hollister, William K., Cortland, N. Y.
Holtz, George, Jersey City, N. J.
Hood, Albert K., Newport, N. H.
Horwell, Thomas H., East Liverpool, Ohio.
Hotopp, Otto A., Hoboken, N. J.
Howard, Charles C., Mt. Vernon, N. Y.
Hutchison, Tom W., Kingston, Pa.
Kearney, James L., Meridian, Miss.
Kelsey, John H., Lowell, Mass.
Kreader, Charles W., Tiffin, Ohio.
Law, Edward M., Fall River, Mass.
Lohr, Edward, Johnstown, Pa.
Mackrell, Henry, Paterson, N. J.
Mangold, John A., Moundsville, W. Va.
McCrobrey, James, Green Island, N. Y.
Meeks, Chauncey S., New York City.
Merkel, Dan'l, Jr., Carlstadt, N. J.
Mitchell, William M., Springfield, Ohio.
Morris, Chauncey R., Falls Village, Conn.
Murhard, C. B., Portland, Ore.
Quellet, John W., Westbrook, Maine.
Pearson, Royal W., Calumet, Mich.
Perry, A. D., Belvidere, N. J.
Putnam, Ralph F., Danvers, Mass.
Reed, Amos J., Pen Argyl, Pa.
Rights, Samuel E., Salem, N. C.
Roberts, D. Leon, Moundsville, W. Va.
Rodman, R. W. A., New York City.
Rosenthal, Ernest C., St. Louis, Mo.
Rouse, T. Brainerd, Colorado Springs, Col.
Schoudel, Irving, Highland Falls, N. Y.
Serfass, Aaron, Ashley, Pa.
Sholes, Ransom S., Jr., Norwich, Conn.
Shumway, Geo. S., New York City.
Stebbius, Frederick A., Williamsburg, Mass.
Studley, Alfred E., Worcester, Mass.
Tolan, Thomas L., Hornellsville, N. Y.
Wagner, Harry, Bayonne, N. J.
Weiant, Albert E., New Britain, Conn.
Weikert, Edward, Canton, Ohio.
West, Edward D., Oberlin, Ohio.
Whelpley, Ed. M., Washington, Ohio.
Whitehead, Henry, Los Angeles, Cal.
Wordell, Abiel H., Fall River, Mass.
Worth, Walter F., Davenport, Iowa.
Zehultz, Louis J., Toledo, Ohio.

VALEDICTORY.

The bricklaying and plastering, painting, carpentry and blacksmithing graduates were then in turn presented with their diplomas; after which the following Valedictory was delivered by Hamilton E. Claflin of Hillsborough Bridge, N. H., a member of the day plumbing class.

The duty has been assigned me to speak farewell words at the closing of this school term. A parting under such circumstances has in it some shade of sadness or regret.

At this hour we may recall with just pride how strangers have become friends. Friendship is a strong word. Its ties bind hearts in common sympathy.

May the friendliness, the mutual hopes and aspirations enkindled here be constant reminders of our Trade School life. The past term has been one full of benefit and pleasant associations to all the students.

If it shall be so ordered by Providence that some of us may not be together again let us cherish happy memories of the term's fellowship.

There is not one who has failed to enjoy the daily school life and who does not feel grateful for the constant efforts of the officers and instructors for our progress and happiness.

In bidding farewell we would assure them of our respect and our appreciation of their earnest labors for our best welfare. The value of their kindly teachings to us is inestimable. May just rewards come to them for all the trials, the care, the sacrifices which have been used for our good and advancement. It behooves us as men to prove a credit to their instructions and thus show to others the advantages of this instruction.

We wish to express our heartfelt sympathy to Colonel Auchmuty in his painful affliction, and our earnest wishes for his speedy recovery, that he may further perfect this most excellent school and enjoy the fruit of his benevolence. We know he is with us in heart, and words fail to express the gratitude we feel for the assistance and inspiration he has furnished to our life's work.

Fellow-students, when we look squarely into the face of life we may read written thereon a real, earnest story. With manhood let us meet life's realities and obstacles. These shall prove our capacities.

Amid all our gettings the star hope of living should be to have manly character. Though knowledge, money, property, principalities pass away before our very eyes, character shall abide and live throughout all time.

Let us hold in mind as we separate tonight the apt words of Fletcher on the true measure of life:

"He most lives,
Who thinks most, feels noblest, acts the best."

The chairman then presented to the students their good friend and his. J. Stanly Thomas, who addressed the young men in part as follows:

ADDRESS OF MR. THOMAS.

In this age, the representative artisan stands for all that is greatest and best in the fraternity of tradesmen, and with common sense judgment declares that the acquisition of dollars does not mean success. As this student body goes forth from these walls to enter upon the avenues of business, they need not be reminded that the mere accumulation of money does not underlie true happiness.

To denounce the possession of money is no less than hypocrisy. To say that it is "a necessary evil" is a false sentiment. Money is a power, and gotten honestly bears testimony to a man's capacities. Rightly used, it transforms aims and wishes into loftier purposes and achievements. Expended wisely and cautiously by a willing spirit of self-sacrifice for the elevation of the interests of the less fortunate and depressed in life, it may determine the development or destruction of locked-up abilities and sympathies. Oh! it is the unwarrantable greed, the callous love of money, that is blighting men's souls and stamping out human happiness.

Virtue is the password to individual and national progress, and duty is the keynote to success. The conscientious doing of individual duty, whether private or public, in addition to earning reputation, adds the golden luster of manliness and holds dear the instinctive perception of what is just and right in business transactions, no matter what others may say or do. Build up character and reputation by labor and merit, that the confidence and good will of those struggling to rise in situation and power may be enjoyed. Never fail to dignify your trade by respecting, encouraging, strengthening its members. Any man whose advancement in the world is pur-

chased by surrendering his convictions and crowding down others is selfish and criminal. Never trample on conscience for worldly gain, and remember that it is a privilege to help onward a brother tradesman.

Courage of honest convictions is the best stronghold amid the vicissitudes of human experience. It will energize failing hope in feverish times of adverse circumstances. If fearless convictions of duty, of truth, of the right incite—intensify many purposes and aspirations, the world will be the better for our living in it, and happiness shall crown our career in life. Habits of industry, of economy, of temperance, a love for the purity and sanctity of our homes, make the ideal artisan. Business methods founded on these elements will inevitably bring success of the best and most abiding sort.

All the rich, touching and beautiful encomiums heaped upon the labors and enterprise of the beloved Colonel Auchmuty, who seems to realize his stewardship to mankind as of divine calling—only hint the ongoing, upbuilding influence of his thought and life upon the industrial classes of men. The celebrated "Auchmuty system" having produced in the past 11 years such remarkable results in the manual and scientific branches of the trades to which it has been applied, has attracted attention in this country and in Europe. Is not the true glory of any institution the record of the students after they enter upon the walks of life? The progress and positions of the New York Trade School students proclaim the expediency and success of the system of instruction used. Their useful career stands as a living monument of its value and influence. And, Mr. Chairman, shall we in our tributes of praise to Colonel Auchmuty forget her whose influence and inspiration have so much helped to eulogize and encourage his mind and heart? For often is woman's sympathy and faithfulness lightly considered. The world to day feels and acknowledges her vast uplifting power for good. Nowhere is woman's influence so felt as in the home. And may the love of wife always keep man truest to all that is highest and best within him and stir to noble deeds the noblest affections of the human soul.

After a few hearty words had been addressed to the classes by Harry Brill, the chairman said that all that remained to be done was to read to the students the letter from their kind friend, Colonel Auchmuty. Mr. Dodge then read the following communication:

COLONEL AUCHMUTY'S LETTER TO THE STUDENTS.

NEW YORK, April 6, 1893.

To the members of the New York Trade School:

It is with very great regret that I have been unable to meet the classes of 1892-93. I write to wish you one and all success and prosperity.

I would call your attention to the fact that the chief secret of success is perseverance. Some may drop at once into good places; but, by the great majority, places are only to be found by seeking for them and not becoming discouraged if not easily found. There are many hundreds of letters on file in the office from those who have preceded you here. Most of them show how those who would not give up finally succeeded.

I hope you will write or call on Mr. Brill from time to time. That your lives may be happy and prosperous and that you will never regret the time you have passed at the New York Trade School, is the earnest wish of your sincere friend,

RICHARD T. AUCHMUTY.

CHAIRMAN'S CONCLUDING REMARKS.

At the conclusion of the reading, Mr. Dodge requested those of the students who wished, in return for his greeting, to send to Colonel Auchmuty their sympathy and respectful congratulations on his returning strength, to rise. This request was followed by a general uprising in the body of the hall accompanied by three ringing cheers for the Colonel, which the chairman remarked would act as a tonic to their friend when he was told of them. At the next celebration he trusted Colonel Auchmuty might be again among them to give from his own lips the words of kindly counsel, full of common sense, which he knew so well how to offer. It was due, said Mr. Dodge, almost solely to the pluck, energy, determination and faith of this one man that the New York Trade School stands where it does to-day.

The chairman then concluded with a few earnest and affectionate words of advice to the young men, in the course of which he pointed out to them that the fundamental secret of succes in life is character. He strongly urged on the young workman as the essentials of a good and successful tradesman the qualities of sobriety, reliability, punctuality, and above all, honesty. Wishing the students success and happiness in the course of the life they had individually chosen, Mr. Dodge brought the formal proceedings to a close with a happy allusion to the perhaps more important function that was to follow, namely, refreshments.

The New Mormon Temple.

On Thursday, April 6, the great Mormon Temple, at Salt Lake City, was dedicated, just 40 years from the day the corner stones were laid. The building is of granite, much of which was hauled to the spot by ox and mule teams, and consists of four stories. It is said that the cost of construction has been about $5,000,000. The temple is built in nondescript style, and is 186½ feet long and 91 feet wide. The granite walls are 9 feet thick at the base, narrowing up to 6 feet. There are three towers on the east and three on the west side of the building, the corner ones being 200 feet and the central ones 222½ feet high. The whole structure covers an area of 21,850 square feet. It is provided with all the most modern appliances for heating, lighting, ventilation and sanitation, and is richly decorated with carved stone work exteriorly, while the interior contains much costly decoration in colored marbles, mosaics and rare stones with which the walls are inlaid, besides beautiful metal work in brass and iron. The assembly room, which is the principal auditorium and place of worship, is on the fourth story of the building and accommodates 2500 persons.

Plowed land in England becomes less and less in area every year. From the official agricultural returns it appears that during the last 20 years the country shows a diminished area of nearly 2,000,000 acres under the plow, or over 14 per cent. Arable land in Wales has dwindled 21 per cent., but Scotland, on the contrary, shows an increase of 78,000 acres.

The total quantity of gas consumed last year in Berlin, Germany, amounted to 4,062,568,000 cubic feet, an increase of nearly 3 per cent. over the year 1891. On the other hand, electric lighting has increased 29 per cent. in the city during the same 12 months, and the importations of petroleum advanced 6.5 per cent.

The Westward Movement of the Center of Population.

In his speech at Pittsfield, Mass., Senator Dawes made pointed reference to the marvelous growth which the Western section of the United States has achieved since his entrance on public life. "The country," he said, "has been widening and going westward and westward to the Pacific Coast, and then on beyond, until the latitude itself fails to chronicle our onward march, and westward falls into the eastward, so that the sun will not go down to night upon our westward border until it shall have risen on the coast of Maine." The continuousness of this growth is shown by the steady westward movement of the center of population. When the census of 1850 was taken, two years after Mr. Dawes' public career began, the center of population was located at a point 23 miles southeast of Parkersburg, W. Va. The census of 1890 puts the point 20 miles east of Columbus, Ind. Here is a westward movement of 229 miles in 40 years, giving an average rate of 5.72 miles per year.

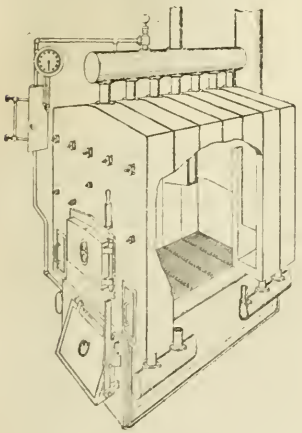
If the measurement is carried 60 years further back, to the first census of 1790, we find that there has been in the 100 years a movement westward of 505 miles, the center of population having passed from a point 23 miles east of Baltimore, Md., to the location in Indiana noted above. The rate of progress for the whole period averages 5.05 miles a year, or 73 feet a day. In other words, for a century the center has been moving westward at an average rate of 1 yard an hour, with 1 foot thrown in every 24 hours for good measurement. The slowest progress was made in the second decade, from 1800 to 1810. In this period the population center achieved only 36 miles of westing, or at the rate of about 2 feet 2 inches per hour. The swiftest progress came in the seventh decade, from 1850 to 1860, when the center moved westward no less than 81 miles, or at the rate of about 4 feet 10 inches per hour. During the last decade of the census enumeration, from 1880 to 1890, the rate dropped a little below the average, 48 miles of westing being made, which would be about 2 feet 11 inches per hour. We may add, to bring the estimate down to the beginning of 1893, that, if the rate of progress noted in the past census decade has been maintained in the two and one half years since the census was taken, the present center is found at a point 8 miles east of Columbus, Ind., about half way between that city and Waynesburg. And the census of 1890 will, at the same ratio, bring it to a point nearly 2 miles south of Unionville, Ind.

It is a curious fact that while the westward movement of the population has covered no less than 9¾ degrees of longitude (9 degrees 21 minutes 7 seconds), this movement has run almost in a straight line, the extreme northern and southern variations embracing less than one-third of a degree of latitude (18 minutes 56 seconds). To put the contrast more distinctly, we may say that while the western movement for the century aggregates 505 miles, the extreme northern and southern variation is a little under 22 miles, and the finishing point of the line is only some 6 miles south of the starting point. The slightness of this variation may be taken as showing that if you divide the United States by the thirty ninth parallel of north latitude the growth of the population in the two sections thus made has been very nearly equal during the 100 years covered by the 11 censuses. In view of the fact that the tide of immigration from foreign countries has set mainly into the northern section, such an equality in the growth of the population is a development that would hardly have been looked for.

STEAM AND HOT WATER.

The Dietrich Heating Boiler.

The accompanying illustrations show three views of a new form of heating boiler lately patented, and now put upon the market by H. A. R Dietrich, South Bethlehem, Pa. The boiler, it will be noticed, consists of cast-iron sections, the broken view in Fig. 1 showing its general construction and indicating the arrangement of headers and the shape of fire pot. In Fig. 2. which is a longitudinal section through the fire pot, the water spaces are shown. Fig. 3, which is a broken view, shows the fire passages and the direction



The Dietrich Heating Boiler.—Fig. 1.—Broken View, Showing Interior of Fire Pot.

of the currents of hot gases on their way to the flue. The general features of the boiler will be understood by an examination of these three engravings. We understand from Mr. Dietrich that the boiler is designed principally for heating and ventilating under gravity conditions. The vertical cast-iron sections have dome and nipple connections and are so placed together that a perfect gas-tight joint, it is claimed, is obtained by the use of a small quantity of asbestos in the openings between the sections. The construction of the boiler permits the use of the entire outside surface as a radiator for warm air. This is done by building a brick wall around the boiler and furnishing cold-air supply to it and conducting it away through heating flues. The boiler proper rests on a cast-iron base, has a shaking grate and all the latest conveniences for automatic control. The combustion chamber is in the top, the draft from the fire being up to the crown of the sections, then to the side and down to the bottom side flues, from where it is carried to the rear and into the smoke box, which is fastened to the bottom of the rear section. By this construction it is pointed out that the water is taken from the hottest part of the boiler and the gases escape from the coolest part. It is also claimed that the boiler is exceptionally clean, as all the heating surfaces are either vertical or overhanging horizontal. The construction, it is pointed out, is such that direct circulation takes place in each section from center to side, thus causing two independent circulations in each section. The boiler is furnished in sizes

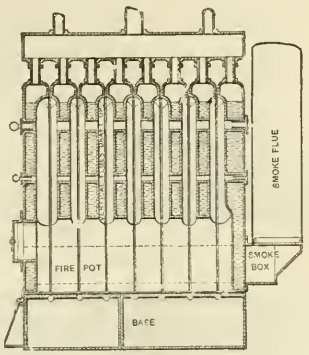


Fig. 2.—Sectional View through Fire Pot.

varying in capacity from 250 to 2500 square feet of radiation. The application of the grate to the boilers is such that a boiler of four sections will have three bars of grate. Thus the No. 1 boiler, with four sections, has an 18 x 18 inch grate, equal to 2¼ square feet, with 56 square feet of fire surface, adapted to heat from 250 to 350 square feet of radiating surface. The No.

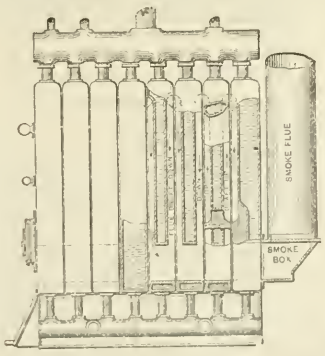

Fig. 3.—Showing Fire Passages.

2 boiler, composed of six sections, has a grate 27 x 30 inches, equal to 5⅝ square feet, and 162 square feet of fire surface, and adapted to heat from 900 to 1050 square feet of radiating surface.

The office of the United States Heater Company, which is the new name of the Capitol Heater Company of Detroit, Mich., is located in the Bagley Building, Randolph and Congress streets. The office on the first floor has a frontage and entrance on either street, and is handsomely finished in quartered oak with furniture of the same material. In all respects it is excellently equipped for the convenience and comfort of the officers of the concern and their assistants.

HEATING NOTES.

At a meeting of the Executive Committee of the Master Steam and Hot Water Fitters' Association of the United States, held Friday, April 7, it was decided to accept the proposition from the proprietors of the Revere House to entertain the steam fitters during the coming convention, which opens in Chicago at 10 a.m., June 6. The Revere House, therefore, will be the headquarters for the sessions of the convention. We learn from Secretary George H. Reynolds that the rates will be $3 and $3.50 per day, including meals.

Dirigo Heater Company, Portland, Maine, makers of the Dirigo hot-water heater, have established an office and showroom at 51 Oliver street, Boston.

W. H. Pennell, a hot-water expert, formerly of Jamaica Plain, Mass., and operating in New England, will now represent the the Model Heating Company, at their office at 144 North Second street, Philadelphia.

A growing interest is manifested in hot water for heating purposes, and is turned to profitable account by John C. F. Trachsel of 246 Arch street, Philadelphia, who makes a specialty of the line of the Gurney Hot-Water Heater Company of Boston, Mass. The operation of the plants he has installed during the past year has been, without exception, very satisfactory.

The Foskett & Bishop Company, New Haven, Conn., issue a circular letter to the trade calling attention to their new organization and stating that they will continue doing the business conducted by the firm of Foskett & Bishop. They are prepared to furnish and erect steam power and heating plants, provide boilers, pumps, &c. They also make a specialty of large and heavy piping for high pressure, as well as general mill work. They further announce that they will make the installation of automatic fire extinguishers a leading feature.

A curious specimen of advertising circular reaches us on the back of a postal card sent by Smith & Winchester, Boston, Mass. The top half of the postal is a panel with the name of the firm plainly printed in the middle, and the rest an undecipherable mixture of capitals and small letters, italics, script and several other forms of type. In some unexplained way, this jumble bears upon the fact that Smith & Winchester will furnish steam, gas, water and plumbing supplies promptly at reasonable prices.

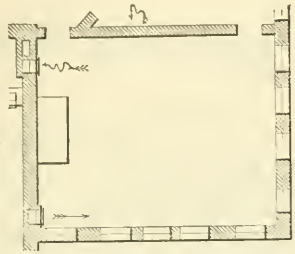
Sealed proposals will be received at the office of the Supervising Architect, Washington, D. C., until May 3, for all the labor and materials and fixing in place complete of low-pressure return-circulation steam heating and ventilating apparatus, and high pressure steam boiler, &c., in the United States Court House and Post Office Building at Duluth, Minn., in accordance with drawings and specifications, which may be obtained of the Supervising Architect at Washington, or at the office of the Superintendent at Duluth.

Heating and Ventilating School Houses by the Blower System.—II.

By Walter B. Snow.

APPLICATION OF THE SYSTEM.

With any system of heating and ventilation, other factors being satisfactory, success or failure may be dependent upon the location of the inlet and outlet registers, and upon their sizes. The best practice now dictates that the inlet register shall be at least 8 feet above the floor level in one of the inner walls of the room, and that the vent register shall be in the same wall, at floor level, or in the floor itself close to the wall. Furthermore, that so far as possible, the heated air shall be discharged toward the coldest and most exposed wall; that in the case of a corner room, it be discharged from an inner wall close along one of the outside walls, and that the vent register shall be in the same inner wall, as far removed from the supply register as possible, all as indicated in Fig. 1. As a result, the air passes above head level to the opposite wall; in its passage by the side wall its temperature is slightly decreased, and a portion gradually descends along the window and wall to the floor; the remainder follows a similar process on the other outside wall, with the result that there is thus produced a downward movement of the air on both outside walls; when it reaches the floor the only means of escape for this air is through the vent register in the inner wall, and consequently the general tend of the air is in a mass diagonally across the room to vent register. In its transit it warms the pupils and removes from them the vitiated air.



Heating and Ventilating School Houses by the Blower System.—Fig. 1.—Arrangement of the Registers.

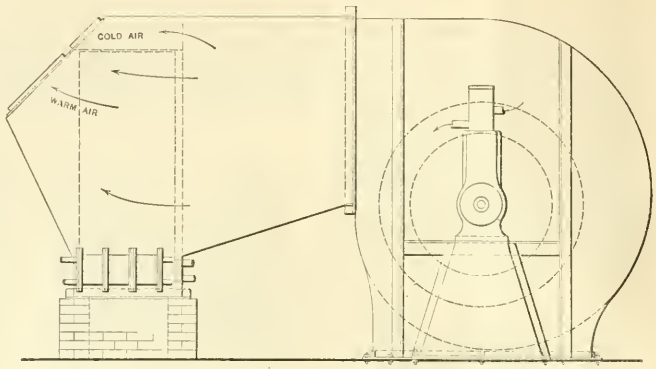


Fig. 2.—Special Hot-Blast Apparatus for Hot and Cold Air.

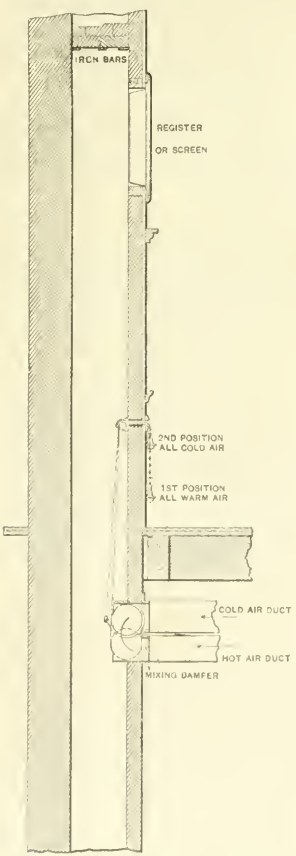

Fig. 3.—Section through Heat Flue.

Of course all air currents impinging upon the person must be at such low velocity as not to be perceptible. Accordingly, the velocity through the inlet register itself must be moderate—not over 50 feet per minute under ordinary circumstances.

ARRANGEMENT OF THE SYSTEM.

Having thus made clear the requirements in the schoolroom let us descend to the basement and follow the air in its passage through the system.

The steam supply, at say 40 pounds, being provided, as under any steam heating system, we may concern ourselves only with the particular features of the blower system.

Although the fresh air supply is often taken from above the roof, yet probably in the majority of cases it will be found to be drawn in through the basement windows from the ground level. In the moderately open country, if the openings are properly located there can be no reasonable objection to this arrangement; but ample area to supply the fan must be provided.

The fan, of the incased type, either paddle or disk in form, is located in or connected with a fresh air room and is driven either by independent or direct-connected motor—preferably steam engine or electric motor. The fan should be of large capacity, so that its speed may be low; likewise the engine—which if possible should be belted to the fan—should be large, so as to drive the fan at its required speed under low steam pressure. A direct-connected engine having a shaft in common with that of the fan is in the position of having any noise transmitted directly into the fan, whence the air stands only too ready to transmit it up the flues to the rooms.

The air from the fan passes directly through the heater, which may be simply a primary heater tempering the air to say 60°, leaving the remaining increment of temperature to be supplied by individual supplementary heaters or coils at the base of each of the flues. Such an arrangement, while having some special advantages, has at least the demerit of extra expense, which becomes more prominent when it is shown that the same results may be accomplished at less expense without the use of the supplementary coils. It is this more economical arrangement that is to be here described.

Placed directly in front of the fan is the main and only heater, capable of heating the air from, say, 0° to 130°. Air to be heated is forced directly through this coil into a system of horizontal ducts connecting with each of the flues. Fig. 2 illustrates a small apparatus with incased fan and direct-connected engine. It will be noted that above the top of the heater proper is a duct or passage through which air may pass without becoming heated. From this passage there is a second set of horizontal ducts immediately above the hot-air ducts previously described, and also connecting to the bases of the flues. The arrangement of ducts and flues is represented in Fig. 3, where is shown at the junction of the ducts a mixing damper, operated by chain from the room above, and so designed that either all hot air or all cold air may be admitted, or they may be mixed in any proportion without changing the total volume. There is thus provided without complication or the objectionable feature of numerous independent coils a ready means of varying instantly, at will, the temperature of the air admitted to any given room, and thereby overcoming the effect of various wall exposures without in any way changing the quality of ventilation.

Obviously these mixing dampers may be controlled by thermostats in the respective rooms, or, if desired, the control of the entire system may be placed in the hands of the janitor.

ARRANGEMENT OF DUCTS.

As shown in Fig. 2, the unheated air passes over the top of the heater and thence the cold air is conducted above the hot air. A reversal of positions is possible, dependent on type of apparatus and location of ducts. If, for instance, they are underground, it will be better to carry the cold air beneath the hot, both ducts being of brick, the cold being separated from the hot by slate, stone, brick or cement on cross carrier bars, or by two separated sheets of iron.

In all the distributing ducts a proportionately high velocity may be maintained. Leaving the fan at about 2500 feet per minute, the velocity should be reduced to 1500 or 2000 feet per minute when the air passes through the mixing damper. The velocity then immediately drops to that designed for the flue, say 800 feet per minute. Of course, the larger the ducts the lower the velocity and the less the loss from friction. But under moderate pressures with a force driven by an engine whose exhaust steam is completely utilized in the heater, the extra expense of moving the air is inappreciable, while the reduction in expense of the distributing ducts

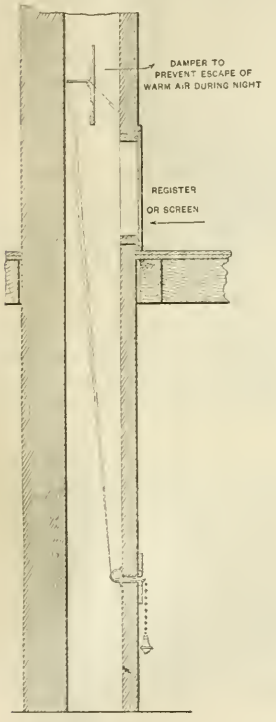

Fig. 4.—Section through Vent Flue.

and the space they occupy is of sufficient importance to receive careful attention.

VENT FLUES.

While with many systems there is required a complicated system of downward vent flues extending to the basement and there connecting with large and expensive aspirating shafts, there is necessary in the hot blast system only the simple flues extending above the roof line with no aspirating arrangement, for the pressure maintained within the room is always sufficient to produce the requisite discharge. In order to economize heat when the building is not occupied, it is best (assuming the inlet and outlet openings to be provided with screens only) to place in each vent flue above its screen a damper controlled from the basement, as shown in Fig. 4, so that no escape of air shall be allowed through the vent screens when the room is unoccupied.

When starting up in the morning, all vent flues should be closed, all doors opened into the corridors, the fresh-air supply to fan closed and all the air for heating taken direct from the building, thus simply heating it over and over. All of the rooms containing sanitary fixtures or devoted to toilet purposes should be provided with direct heat and have no hot air discharged into them, but be generously supplied with vent openings. The benefit of this arrangement is twofold: it allows of keeping heat on these rooms only and thereby preventing freezing while the rest of the building is shut; it furthermore, by the omission of the hot air supply, causes all drafts to be inward and prevents the possibility of escape of odors to the remainder of the building. The vent from the sanitaries should be carried into the space between the iron boiler stack (if such is used) and its surrounding chimney proper. A stove with its smoke pipe extending up this space should be provided for use to produce effectual ventilation when the boiler is shut down.

ECONOMY OF SPACE.

The general compactness of the blower system must be at once evident. All of the supply pipes are usually carried overhead in the basement, occupying no valuable space. The entire apparatus can ordinarily be placed in a single room of moderate size, usually within the limits of a single schoolroom.

The alledged compactness of this system cannot be better evidenced than by contrasting the cellar plans of similar school buildings heated by the blast and by the hot air furnace systems. In a case in mind where furnaces are employed, two basement rooms are completely occupied and two others to a large extent by the four furnaces with their fresh air rooms. A large amount of wall space is also required for large heat and vent flues and the numerous smoke flues, each with its individual stack heater. The blower system for a similar building, on the other hand, as illustrated in Fig. 5, is contained in a single room, all of the distributing pipe is overhead, out of the way, the flues do not occupy valuable space—in fact, the building with the blower system may be made smaller than when the furnace system is applied.

With the blower system the first cost is always less. When the expense of the flues is considered, the cost of actual time consumed in attendance is less, as only one fire must be tended instead of four and the coal bill will be found to be well inside that for the furnace system. To this must be added the ever-present advantage of positive action under all climatic conditions.

The furnace system has long been in the field; the indirect or direct with its aspirating shafts has followed at a later date and the blower system in the form here described is a product of the last three or four years — although isolated earlier examples may exist.

Every intelligent engineer, conditions permitting, is now ready to install the blower system in some form; but he must await the convictions of the builder, the owner or the officials in authority before he may be permitted to introduce this economical, efficient and health sustaining system in the place of the arrangements so frequently specified.

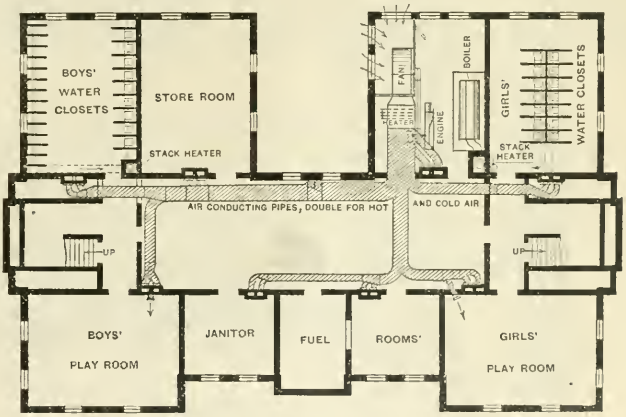

Fig. 5.—Arrangement of Blower System.

THE DIRIGO HEATER COMPANY, 51 Oliver street, Boston, Mass., distribute circulars describing the Dirigo hot-water heaters of their manufacture. An accurate description is given of the apparatus, and particular attention is bestowed upon the heating surfaces and the feature of circulation. Table of dimensions and prices are appended, and a number of testimonial letters are given.

Suggestions for a Spelling Bee.

The *American Chemical Journal* for March contains some reading, which, judging by the titles of its articles, could not be classed as "light literature." The following are the names of some of the papers included in this number: "On Chlorsulphopyromucic Acids"—a treatise which, by the way, contains such awe-inspiring compound words as "baric-chlorbromfurfuransulphonate"; "On M^e, thylfurfurol and Methylpyromucic Acid, in which fearsome substances, entitled, "dibrommethylpyromucic acid" and "methylpyromucicetrobromide," are mentioned; "On Amidophosphoric Acid," treating of such light and airy things as "diphenylamidophosphates" and "phenylamidophosphoric acid"; with a concluding paper, "On the Action of Succinimidebromide or Sodiummethylate in Dilute Solution." To the scientific chemist these polysyllabic nouns doubtless convey great ideas, and to the digger among Greek and Latin roots they would offer a rich field for investigation; but to the laity in general these papers might prove a trifle too abstruse.

The Compagnie Transatlantique strongly advocates the lighting of the Atlantic route from Ireland to Newfoundland. It is proposed to put ten powerful flosting lights 200 miles apart, and connect them by electric cables.

PLUMBING AND GAS FITTING.

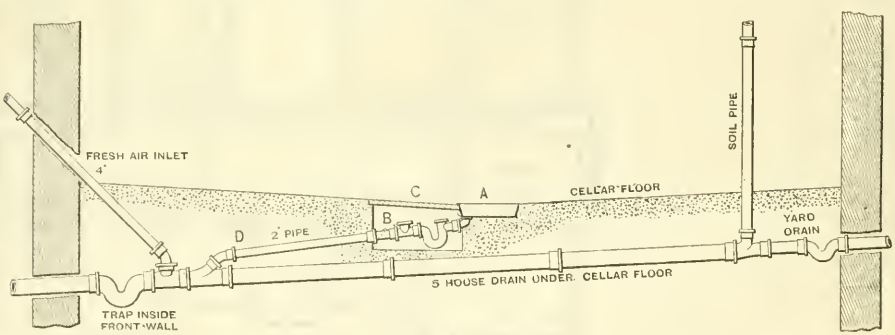
The Chicago Master Plumbers.

The regular meeting of the Chicago Master Plumbers' Association was held at 206 La Salle street, Monday evening, March 10, a fair attendance of members being present. The association indorsed the application of Andrew Young for chief tenement, factory and smoke inspector; also that of William H. Denung for secretary of Chicago Building Department. Jacob Kiessling, 1199 Milwaukee avenue, and Daniel Sullivan of McCann & Sullivan, 463 Forty-seventh street, were elected members of the association. Those who applied for membership were Peter Gow, 858 North Rockwell street; Henry B. Foster, 800 West Twelfth street; G. J. Julien, 430 West Twelfth street; Richard T. Ward, 1487 Harrison street, and John Leibolt, 311 West Twelfth street. Secretary Alex. W. Murray having been invited over to the house warming of the Builders and Traders' Exchange, Alexander F. Irons acted as secretary for the evening.

Cellar Surface Drainage.

From E. G. M., *New York.*—Your reply to the inquiry of "G. F. R." in *The Metal Worker* of March 11 appears to me to favor a very elaborate system of cellar subsoil drainage. Your plan calls for a sunken sink instead of a perforated plate, and a trap and flap valve, which seems to be more than is at all needed. Then, as regards the fitness of either the globe or gate valve to serve the purpose of a cut-off valve, there should be no difficulty in flushing out whatever of grit or ashes would find a lodgment therein. The flap valve, as is well known, may be all right at the beginning, but a very little thing will serve to prevent the flap from closing tight after the passage of water, or rather matter, through the pipe, and then there is no way to get at it. Why not let well enough alone, and put only a trap under the strainer at the mouth of the pipe? If the Board of Health or the Building Department require something else, let them tell the plumber what is necessary to have the work in the building passed. There is another thing also to be considered, and that is how the cellar is generally finished. How many of them do you think are properly graded so as to throw surface water to a given depressed point? Not one in 50, unless the contractor is looked after, and it does not always pay to be looking after other people's work.

Answer.—Our correspondent has not, evidently, considered the subject on which he writes in a spirit free from prejudice in favor of whatever system he has been carrying out himself. Let us see what are his objections. The first is the sink in the floor, presumably because he thinks it might be dispensed with and a perforated plate substituted. There is, in the first place, no saving, because good sanitary practice requires safes under all fixtures and safe waste pipes therefrom carried into the cellar to discharge into a trapped and water-supplied sink. It should therefore cost less to put a sink in a cellar floor which will answer the double purpose of a perforated grating for surface drainage and a receptacle for the occasional discharges from the safe wastes. A sink on the cellar wall with trap properly vented, and waste carried to house drain, will be much more expensive. Our correspondent does not suggest a means of flushing out the globe or gate valve while he suggests such a course. Where is the water? Surely not what runs off the cellar floor, for even if it were clear it has not sufficient force to wash anything out of its way. Again, he must bear in mind that the flap valve is not intended to keep out sewer gas, as the water-supplied trap will do all that. The flap valve preserves the cellar against the backing up of the sewage in case the house drain becomes choked; that and nothing more is its mission, and a glance at the diagram published herewith will show that a man-hole is provided with movable cover, through means of which both sink and flap valve are reached. As regards the cellar floor if the plumber neglects to have the concrete man make provision for his subsoil drain he should not expect his work to be accepted. In the diagram A represents the sunken sink, toward which the floor is properly graded, B the flap valve set on the 2-inch pipe D, while C represents the man-hole fitted with removable cover (generally a slab) through which obstructions can be removed either from trap or valve. The furnishing of a water supply, which, however, is not shown, is, after all, the best feature of this system, as it insures a constant seal for the trap on which our correspondent depends, without troubling himself how the said trap could keep out sewer gas if there should happen to be no water on the cellar floor for any length of time.



Cellar Surface Drainage.

Plumbing Vent Pipes.

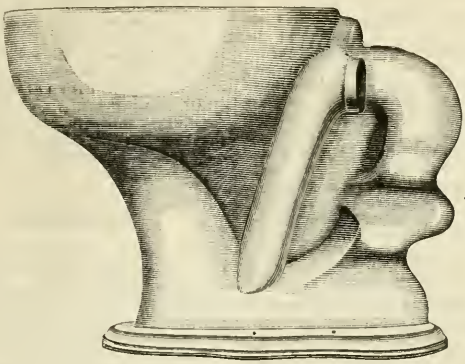
From A. B. C., *Watertown, N. Y.*—Please answer through *The Metal Worker* the following questions and oblige a constant reader of your paper: What is a local vent as applied to a plumbing job? What is meant by back-air vent as applied to plumbing?

Answer.—The term "local vent" is applied to a vent pipe which is intended to be carried from the bowl of an earthenware water closet into a heated duct or flue for the purpose of carrying away the odors from the closet bowl during its actual use and which would otherwise become diffused through the atmosphere of the room. Only a small proportion, however, of the total number of closets having this opening in the bowl is fitted with this pipe because of the difficulty of turning it to advantage. Some of the large office buildings of the period have the local vents so arranged that they branch into a horizontal pipe set above the closet and which connects with a vertical vent pipe carried upward in close proximity to a live steam pipe, in which cases the necessary ventilation is secured and the odors of the closet are carried away before the atmosphere of the water-closet apartment is vitiated. When the aperture is not used for local vent purposes the plumber plugs it with plaster of paris or other material suitable to the purpose. The term "back air" is a trade term for the vent pipe of traps—the function of which is so well under-

stood that no explanation is necessary. When a trap is said to be "back aired" it is then known to be vented in conformity with sanitary usage.

The D. & D. Syphon Jet Closet.

The D. & D. Syphon Jet Closet, of which an illustration is here presented, was brought out by the firm of Dale & Davis, Potters, Trenton, N. J., and has, we understand, already received favorable comments from the trade. The novelty of this closet consists in the shape of the syphoning duct or descending leg, the flattened portions of which are at right angles to each other, or alternately, and thus give a twisting motion to the descending water. Without lessening the



The D. & D. Syphon Jet Closet.

area of the bore this twisting motion gives the required retardation to the outflow, and the resulting advantages are that, with a minimum amount of water, the smallest size of flush pipe, and with a moderate hight of tank, a perfect syphonic action, it is claimed, is maintained till all the contents of the basin are expelled. The improvement was designed by Mr. Smith, the inventor of the syphon jet closet. It is neat in appearance, and can be obtained in plain white or ivory and it is also made embossed and decorated. The form of closet is controlled by a patent granted March 7, 1893, and assigned to Dale & Davis.

Wiping Stop and Waste Cocks.

From A. C. M.—Please inform me through the columns of *The Metal Worker* if, when wiping a stop and waste cock with plug out, it is better to put the cock in when the plug is hot or wait until it is cold. Please give reason for or against either practice.

Answer.—The practice of removing the plug or core of a stop cock was long ago condemned, and is no longer followed in good work. The object of the removal was to get the full effect of heat more readily, and, if still practiced anywhere, the cock should be allowed to cool before restoring the plug to its place, so as to allow the expansion and contraction to take place under the same circumstances. As already stated, however, good workmen wipe on stop and waste cocks without any dismemberment during the process, and it would apparently be the better plan for our correspondent to keep pace with the times and discard such methods as have been abandoned by the trade.

PECK BROS. & Co., New Haven, Conn., manufacturers of plumbers' brass goods and supplies, have opened an office and fitted up showrooms at 65 Oliver street, Boston, Mass., in charge of W. B. Hubbard.

TRAPS AND VENTS.

JOHN BYRNS, who is not only well-known in plumbing circles in New York, but also well known to all the prominent master plumbers of the country, through his connection with the National Association of Master Plumbers, has opened a new office at 1215 Lexington avenue, which he will run in addition to his old place at 425 Grand street, New York.

PRESIDENT J. SHEEHAN and TREASURER W. E. GOODMAN of the National Association of Master Plumbers were in Chicago Saturday, April 8, and while in the city were entertained by the officers of the Chicago Association.

A. L. BOGART, 22 Union Square, New York, an electrician of long practice, has invented and patented a large variety of electric appliances for gas lighting, call bells, annunciators and burglar alarms. One of the latest is a portable gas lighter and turnkey, to supplant the wax taper. It consists of a metallic handle of dark color, on a nickeled tube, with the turnkey at the end. A dynamo is concealed in the handle and operated by pressing the thumb on a lever, when sparks are emitted at the end ample to light any burner.

HENRY HUBER *et al.* against the Nelson Mfg. Company for infringement of a patent for improvement in water closets brought forth an opinion in the Supreme Court of the United States. Huber held the patents as assignee of two Scotchmen, who obtained English patents in 1874, and then allowed them to lapse at the expiration of seven years by neglecting to pay a fee of £100, which would have given the patents an extension of life for another seven years. The American patent contains on its face a declaration that it was issued by reason of the English patent. The American patent was not applied for until 1882, when there was no English patent in existence. The court holds that under Section 4887 Revised Statutes this American patent is void, having been applied for when there was no existing English patent. Justice Blatchford announced the opinion.

SEALED PROPOSALS will be received at the office of Supervising Architect, Washington, D. C., until May 5, 1893, for all the labor and materials required for the interior finish of the United States Post Office Building at Canton, Ohio, including plumbing, lathing, furring, plastering, wood stairs, marble work, joinery work, wood flooring, glass, hardware, painting, polishing, &c., in accordance with the drawings and specification, copies of which may be had at the office of the Supervising Architect, Washington, or the office of the Superintendent, at Canton, Ohio.

Southern Pig Iron Freights.

The Louisville & Nashville Railroad Company have issued a new tariff on pig iron from Southern furnaces to points north and west, the advances being effective April 13, and the reductions April 6. The rates are per ton of 2268 pounds, when in carload lots of not less than 17½ tons. The rates between some of the more important points are given below:

To	From— South Pittsburg, Tenn.	Chattanooga, Tenn.	Birmingham District.	Sheffield, Florence, Decatur, Ala., Rockdale, and Napier, Tenn.
Pittsburgh District, Pa.	$3.81	$3.90	$4.40	$4.15
Alliance, Ohio	3.26	3.35	3.85	3.60
Ashtabula, Ohio	3.36	3.45	3.95	3.70
Atchison, Kan.	4.87	5.00	5.00	4.55
Aurora, Ill.	3.47	3.60	3.85	3.60

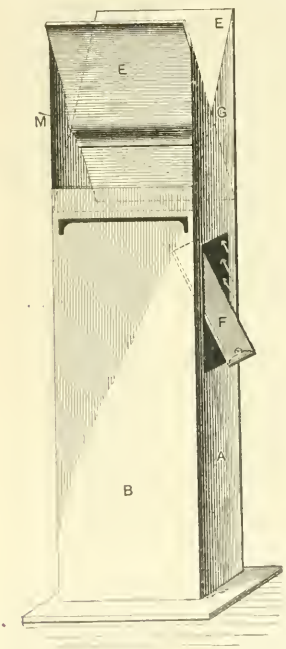
The Nova Scotia coal mines produced last year 1,752,000 tons, of which only 14,000 tons were taken by the United States.

ROOFING AND CORNICE.

An English Chimney Top.

In the accompanying illustration we present a general view of a chimney top which has recently been brought to the attention of the building trades in England. It is so constructed as to prevent down drafts, while increasing the up drafts, and is offered as a remedy for smoky chimneys. It is rectangular in cross section, and the inventor states that by a slight alteration it can be used as a ventilator to carry off vitiated air or dangerous gases from pipes connecting with the basement of a building or with sewers. In the construction of the device here illustrated the top is provided with a metallic shutter or flap, marked E, which works on bear-



General View of an English Chimney Top.

ings, G M. It is arranged to oscillate from side to side, the base resting against either one side or the other, according to the direction of the wind. The lower end of the metallic flap E is less distant from the bearings G M than the upper end, so that the latter is tilted according to the direction from whence the wind is blowing. The added weight of the upper end retains the portion E in position until it is reversed by a current of air in the opposite direction. In either case, however, the shutter E prevents the air from entering the chimney in a downward direction, while facilitating up drafts. The metallic shutter F, shown in the side of the device, is deflected at times by the action of a passing current of air, as indicated in the engraving. This causes a strong upward draft, so as to carry off the smoke and increase the current of air that is flowing upward. The lower end of the flap E is weighted, so that when the pressure of the wind decreases the flap assumes a more vertical position.

Leaks in Tin Roof.

From E. W. F., *Astoria, Ill.*—There is a flat-seam tin roof of 20 squares in our place that was put on in 1867, a good quality of IX 20 x 28 tin being used. The roof has been kept well painted, and the tin is bright under the paint, but for the last two years it has been cracking at the seams and leaking badly. The broken seams have been soldered, but after the first snow or rain there will be more broken seams and more leaks, as the seams break open after they have been soldered. What method is the best to employ for repairing the roof?

Answer.—While the surface of the tin under the paint may be bright, as would be the case if the roof was well painted, it is possible the tin is rusting through from underneath. This can be caused by the condensed moisture from below or by the leaks our correspondent mentions. If such is the case, it will be difficult to repair the roof so as to make a durable job. If the tin is in good condition, and the broken seams are caused by the expansion and contraction of the metal, in place of soldering them in the usual manner the experiment could be tried of soldering strips of tin over the cracks. These strips can be about ¾ inch wide, and bent slightly through the center so as to prevent warping when being soldered.

Measuring Standing Seam Roofing.

From H. W., *Williamsport, Pa.*—In reply to "R.," Rhinebeck, N. Y., whose letter appears in *The Metal Worker* of April 1, regarding the measurement of standing seam roofs, would say that I have had many years experience in tin roofing, both in Pennsylvania and in New York State, as far east as Dutchess County, and as far west as Cattaragus County and intermediate places, but have not found it customary anywhere to measure the standing seam, the flat seam only being measured. I do know of one instance where a tinner tried to but was not successful, because the owner would not submit to it. I have been asked the question if it were practicable to do so, but my answer has been that I did not think it was, because what I lose in tin in a standing seam I more than compensate for in time required to put it on. In fact, I prefer to put on a standing seam roof to a flat seam roof, and in all cases where I can, if there is fall enough to warrant it, do so. And there is fall enough for a standing seam roof in 1 inch to the foot. If care is taken to make a good seam, a standing seam roof is much better than the flat seam, on account of contraction and expansion.

From A. B. C., *Indiana.*—In reply to a recent correspondent who makes inquiry about the measurement of standing seam roofs, I think it correct to not measure the standing seam. Measure the roof simply as if they were made flat. As hips and valleys require more work and waste of materials it is right to measure them double. Some tinners have one price per square for all kinds of roofs, and make no difference between the price for the roof of a barn or of a house. The one is usually without flashings, chimney fittings, gutters or valleys, and has long strips, while the other usually has all of these and short strips. Of course, the house requires more work, and a higher price per square should be charged. The pitch of a roof ought to have something to do in determining the price.

FLASHINGS.

The Fostoria Steel Roofing Company of Fostoria, Ohio, have issued from the press an illustrated catalogue and price-list of steel roofing, corrugated iron and other specialties with which they are prepared to promptly supply the trade. In issuing this catalogue special attention is called to the quality of roofing, siding and eave trough as manufactured by the company, who state that they employ the best material and have added to their plant new and improved machinery for the manufacture of roofing, spouting, &c. The goods covered in the publication before us include V crimp, clapboard siding, patent slip joint eave trough, steel hangers, corrugated patent conductor pipe, strainers, cut-offs, &c. Numerous illustrations are given showing the various lines of goods manufactured, while tables, rules for measurement and general directions will be found of interest to the members of the trades addressed.

Elisha Hawes of Sacramento, Cal., has patented a form of metallic lath so made as to hold the mortar in place while at the same time the thin metal sheets are stiffened. The lath consists of strips of sheet metal transversely overlapped and secured together by clinches at intermediate points. The overlapped parts of the strips are provided with edge folds and intermediate stiffening ribs. In each sheet are backwardly curved projections sufficiently numerous and close together to properly hold the mortar.

J. C. McFarland, manufacturer of cornices, skylights, &c., 2511 to 2519 State street, Chicago, has at present 150 men in his employ. Great efforts are being made to have the new depot of the Illinois Central Railroad at Twelfth street ready for occupancy by April 17. The men employed on the building are working until 11 o'clock at night by the aid of electric lights.

We are indebted to Scott & Company, 75 East Front street, Cincinnati, Ohio for a catalogue of 16 pages relating to roofing specialities. The matter contained within the colored paper covers in which the pamphlet is bound relates to iron and steel roofing, siding, ceiling, gutters, spouting, iron doors and shutters, graphite paint, &c. The illustrations are numerous and the letterpress carefully describes the special features of the goods made and the manner in which the work is applied

THE RETAIL STORE.

Stove and Tin Store.—V.

BY VETERAN.

A tin shop cannot be short of tools and machines without ultimate loss instead of gain. What can be more reasonable than to supply a shop with every tool or machine that will save labor when all the tools made for hand power combined do not cost as much as one year's labor of one man? The machines, if well-used, properly oiled and cleaned, will last at least 25 years, and even then possess some value. I do not think a number of workmen need any greater variety of machines than a single one, unless they are duplicates of those most frequently used, like the small turner, burring machines, square stake, mandrels and small tools. Suppose that $100 worth of useful tools and machines are dispensed with to save their cost, that amount can be saved when 40 days' time has been saved and the tools will then be possessed and in good order.

It is the same with benches. They may be put up for a song out of any cheap lumber, but it pays to have good, wide, heavy hardwood benches, securely fastened down, with cast-iron plates for the stakes and a strip of angle iron at the front edge for bending sheet metal. Each workman should have his small tools—like hand shears, chisels, punches, hammers, mallets and files—and be held responsible for them. If there are only two men in a shop one of them should be the foreman and the one to look to when things go wrong. The foreman should keep the time of the men, not only for their pay roll, but should note down when a man goes out on a job, the time of day, what he takes in stock, and the time when he returns, and what he brings back. It is too important to be all left to the workman. Perhaps he will report correctly when he knows his error would be detected; but experience shows that there is too much guess work when the ordinary workman is not looked after. This can be attended to by a clerk in the store if preferable.

There is profit and satisfaction to be gained, as well as a duty to be performed, in keeping up the supply of tinsmiths by having an apprentice in the shop. If a boy is carefully selected, with due regard to intelligence, mechanical taste, honesty and morality, he will be worth much more to his employer than just what his work amounts to. Unlike the workman, he is a fixture for a term of years, and should be treated as well as he would be in a school and made to act as a helper in the absence of the foreman in guarding his employer's interest. The writer has kept up a correspondence and friendly intercourse to the present day with some of his "boys," that are now gray-haired men, and his regard and friendship for his own "boss" only ended at his death.

Among the Stove Dealers of Western Connecticut.

Journeying through the Nutmeg State one may find at Stepheny Depot a quiet, unassuming dealer, John Benedict by name, who has been in business there since 1865, and judging from his surroundings, he has made a success of the tin and stove trade. Mr. Benedict makes a specialty of the Acorn and Andes stoves and ranges. Occasionally he puts in a furnace, and lately has been using the Howard furnace, which has attained considerable reputation in Central New York and elsewhere.

E. J. Hall carries on the stove and tin business at Sandy Hook with a considerable degree of success. He also has a branch at Newtown, 2 miles distant. Mr. Hall for the past few years has been selling the Garland stoves and ranges as his leading line, and he speaks very highly of the smooth casting of these goods. He also handles the Spicer Stove Company's Model Grand range.

High among the hills and beautifully situated lies the village of Ridgefield, where Peter McGlinn carries on the plumbing and tin business. Mr. McGlinn sells the Bay State and Manhattan stoves and ranges. He has been in business in that place since 1889, succeeding Frank Main.

Henry Foggerty is also here and makes a specialty of driving wells, besides representing the Richmond Stove Company of Norwich, Conn.

Probably no city of Connecticut has more enterprising stove and hardware dealers than Danbury. Situated on the main street will be found the large and beautiful stove and hardware house of C. S. Andrews. The building, a three story brick structure, was recently erected by the occupant and is especially adapted to his business. There are three large show windows, which are always tastily arranged Mr. Andrews carries a large stock of heavy and shelf hardware, crockery, china, glassware, also agricultural implements and harness supplies. He sells exclusively the Richmond stoves and ranges.

C. W. Hull & Co. also carry an extensive line of hardware, agricultural and mill supplies. For several years this house has made a specialty of the Bay State and Garland stoves and ranges, selling a few of the cheaper lines of other manufacturers. They now occupy their new store, which they recently erected on the old site, their former store having been destroyed by fire about two years ago. They do an extensive business. Mr. Young, who does the buying, is well liked by the traveling salesmen.

M. A. Duane, although not on the main street, has a large force of plumbers and tinners at work and makes a specialty of the Andes and Glenwood stoves and ranges, receiving in 1892 first premium at the Danbury fair for the finest display of goods.

The J. M. Ives Company, although a large furniture and crockery house, do considerable stove business as well. For several years they have made a specialty of the Acorn parlor stove and use the West Shore range as their leader.

Retail Hardware Dealers' Association.

The trade will be interested in the announcement that an association of retail dealers was organized at Titusville, Pa., March 30, the object being to promote the interests and secure the friendly co-operation of retail Hardware dealers. Another object closely connected with the general purpose of the organization will be to prevent as far as possible the practice of manufacturers and jobbers selling to consumers, which is so common in certain localities. This, it is hoped, will be accomplished by each member declining to patronize concerns which thus encroach upon the retailers' legitimate field. The entrance fee, including dues for the first year, has been fixed at $5. The officers elected are as follows:

President:
J. P. FRAZIER, Franklin, Pa.
First Vice-president:
H. W. PICKETT, Warren, Pa.
Second Vice-president:
C. J. KIRK, New Castle, Pa.
Secretary and Treasurer:
S. S. BRYAN, Titusville, Pa.
Directors:
M. H. CLARK, Jamestown, N. Y.
R. L. KERNOCHAN, Titusville, Pa.
F. N. CHAMBERS, Oil City, Pa.
D. C. WELLER, Erie, Pa.
JNO. S. LESLIE, Sharon, Pa.
D. ARTHUR GILL, Meadville, Pa.

In addition to the above gentlemen, the following are the original members of the association:

A. S. PINNEY, Erie, Pa.
MEHL & SAPPER, Erie, Pa.
C. FLECKINGER, Erie, Pa.
ZUCK HARDWARE COMPANY, Erie, Pa.
SCHNEIDER BROS., Erie, Pa.
MURPHY BROS., Erie, Pa.
J. PETER ROSTATTER, Erie, Pa.
GEO. MALONEY, Franklin, Pa.
H. SPITTER, Titusville, Pa.
P. B. CARY & CO., Dunkirk, N. Y.
BLOSS & WELNER, Dunkirk, N. Y.
JOHN PORTER, Meadville, Pa.
C. M. HOPKINS, Union City, Pa.
R. EDMONDS & SON, Warren, Pa.
RICHARDS & RICKARDS, Oil City, Pa.
HASLETT, SNYDER & SHAUER, Oil City, Pa
McKERROW & GRAHAM, Oil City, Pa.
CARSON & RIDER, Oil City, Pa.

Any reputable retail Hardware dealer is eligible for membership. The secretary, S. S. Bryan of Titusville, Pa., will be glad to receive applications for membership and will answer all inquiries promptly. Great enthusiasm has been manifested so far and a large increase in membership is looked for. The association is organized under very favorable auspices and the trade in all parts of the country will be interested in its success.

THE FIRM OF SPATES BROTHERS, dealers in stoves, tinware and general hardware, at Eastport, Me., has recently been dissolved by mutual consent. John W. Spates, the senior member of the firm, has taken a fine store in the Hayscale block, where he will do a stove and tinware business, while William T. Spates will occupy the old stand.

Housekeeping Devices.

August Kreamer, manufacturer of house furnishing goods, 17 to 23 South Third street, Brooklyn, N. Y., is continually adding to his line of desirable specialties, in addition to a full assortment of tin, sheet iron and copper pieced ware suitable mainly for fine trade.

The stove-blacking box, illustrated in Fig. 1, is designed to keep together and in one place the implements and materials used in blacking stoves, ranges, &c. Neat housekeepers often keep a pair of old gloves to slip on for this occasion and use

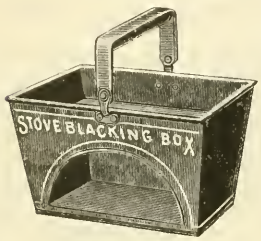


Fig. 1.—Blacking Box for Stoves, Ranges, &c.

cloths and brushes in applying the polish. The lower compartment is intended for cloths, gloves, &c. In the upper portion, the bottom being about 2 inches deep, may be kept polish, dauber and brushes. The article is made of heavy tin, being 11 inches long at the bottom, 13 inches at the top and 8 inches wide, with a substantial handle. It is brown japanned with bronze lettering. Fig. 2 represents a housemaid's pail, to be used in scrubbing, &c., constructed of stout material and all in one piece, the various parts being rigidly attached to each other. The pail is of ordinary size, 11½ inches at the top and 9 inches deep. The extreme width of basin is 16½ inches. At the left

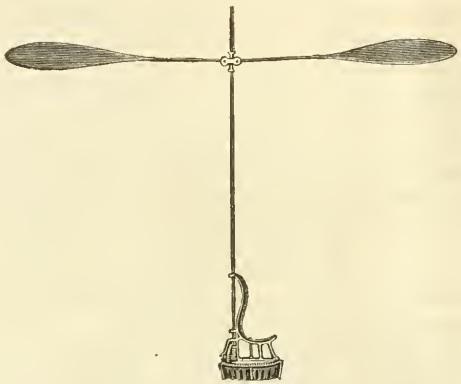
Fig. 2.—Housemaid's Pail.

is seen an attachment in which the brush may be placed after use, which both insures its being properly drained and found when next wanted. On the right is a receptacle with a perforated bottom for soap. The pails are painted a light blue or green tint inside and various colors on the outside. Another convenience, not illustrated, is a tin box for keeping the long narrow loaves familiarly known as French bread. It is of heavy tin, with a hinged cover and clasp and of the following dimensions: Length, 28 inches; hight, 12 inches; width, 10 inches. It is brown japanned with the words "French Bread Box" lettered in bronze. It has a capacity of ten or a dozen loaves.

BRADLEY & BRIGHAM, stove dealers and plumbers, at Marlboro, Mass., are about making some alterations in the interior of their store on Lincoln street. We understand that the front of the salesroom is to be built out to the street line, modern show windows substituted for those now in use and other changes made, which will give the firm additional facilities for conducting a steadily increasing business.

The Columbia Fly Fan.

Matthai, Ingram & Co., Baltimore, Md., and 42 Cliff street, New York, are introducing a keyless fly fan, as shown herewith. It is wound by holding the base in

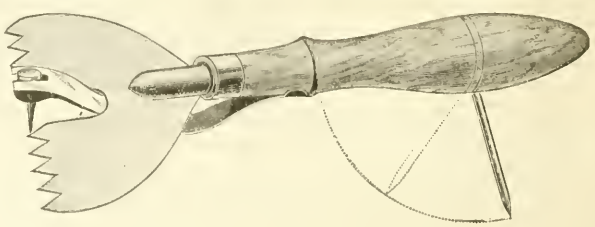


The Columbia Fly Fan.

one hand and turning the wing holder in the other. An automatic stop allows the wings to be stopped instantly, when the wing rod is lifted or taken off, and the wings revolve as soon as the wings and rod are replaced, the weight of the wings and rod releasing the stop. The manufacturers state that the fan will run effectively one hour after each winding. It is finished in nickel or antique bronze. The wing holder is referred to by the makers as resembling to some extent the outlines of a Columbus or a fifteenth century vessel, and the base and movement that of a modern propeller.

Combined Carpet Stretcher and Tack Holder.

The household tool illustrated herewith is being introduced by Wm. Vogel & Bros., 37-47 South Ninth street, Brooklyn, N. Y., as selling agents for H. Clayton & Co. The device consists of a polished steel plate, 3½ inches wide, with teeth, the plate being fastened into a substantial wood handle. A steel spring forming the tack holder is attached at one end to the lower side of the handle, the other end coming up through an opening in the blade. A steel pin is hung in the handle and folds into a groove when not in use. In stretching carpet a tack is placed in the



Combined Carpet Stretcher and Tack Holder.

holder, and the pin in the position indicated by the dotted lines. The carpet after being brought up to the base board is held in place by the pin until the tack is driven half way in by a blow of the hammer, when the stretcher is withdrawn and the tack driven home. The stretcher measures about 9 inches over all.

The Eli Washing Machine.

The Boss Washing Machine Company, Cincinnati, Ohio, are introducing the above washer, as illustrated herewith. The working parts of the machine are described as consisting of a corrugated cylinder for rubbing and turning the clothes, with the

The Eli Washing Machine.

handle for operating set back of the machine, turning loosely in the hand. The manufacturers claim that the machine cleanses the clothes more thoroughly than could possibly be done with an old-fashioned board; that the washer is so arranged that it is impossible to tear the clothes, and that it is so simple in operation that a child can work it without fatigue.

New Idea Double-Acting Spring Hinge.

The illustrations shown herewith represent a double acting spring hinge being introduced by the Stover Mfg. Company, Freeport, Ill. The hinge is made up of a jamb plate having ears, upon which is hung the leaf. It also has a stationary steel pintle to swing on, and it is impossible, it is stated, for the door to sag. As shown in Figs. 1 and 2, the hinge divides at the center (pintle line) by removing four screws. This arrangement, the makers remark, makes it easy to fit the leaves to the door, and to attach the jamb plate to the jamb. Attention is called to the fact that it is not necessary to round off the edge of the door, as the jamb plate and strip is concaved, allowing the corners of the door to pass through the circle of concave; also that the rear joint of the door is always covered, whether the door is partly or wholly open or closed. The working parts of the hinge are confined entirely within the jamb plate, Fig. 3, admitting, it is claimed, of its being taken apart and applied to the door with ease, and without danger of injury to the workman. Fig. 3 also shows the hinge as applied to the door, and gives a top and side view of the concave strip attached to the jamb. The hinges are made in japan and ornamental finishes, and in sizes for doors from ⅜ to 3 inches thick.

Fig. 1.—Hinge Divided at the Pintle.

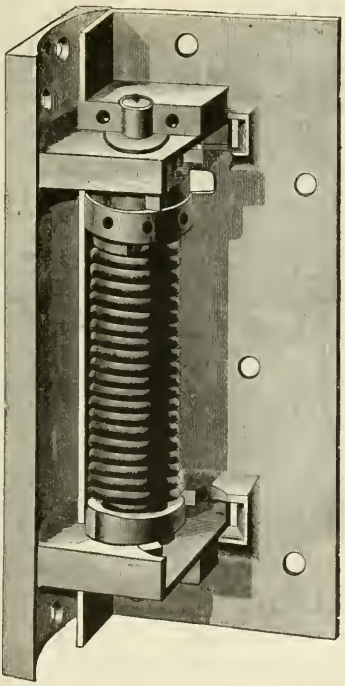


Fig. 2.—Leaf of Hinge in Position.

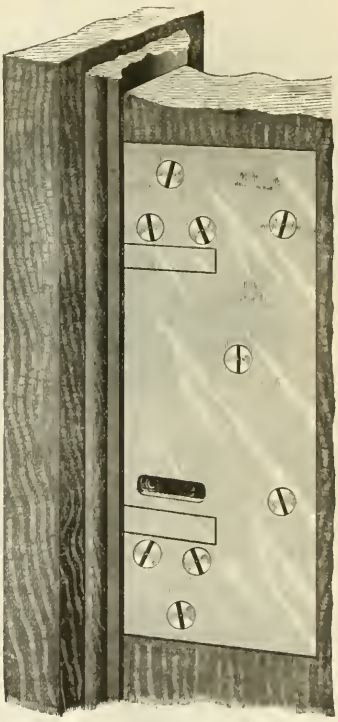

Fig. 3.—Double-Acting Spring Hinge Applied to Door.

The responsibility of retailers seems to be infinite. An English contemporary mentions a recent case in which judgment was entered against a London grocer for £50 in favor of a lady customer who slipped on a piece of bacon and fell on the floor of his store, injuring herself severly. The judge, in rendering his decision, said that whoever cared for the floor should be careful to keep it free from those substances that are dangerous to customers.

Suggestions as to Improvements in Putting Up Goods.

FIRST ARTICLE.

BY BERNARD B. NEAL.

I take it for granted that manufacturers understand very distinctly that the bulk of their goods are finally sold at retail in small quantities. Also, that it takes a great deal of time and labor to retail enough Hardware to amount to much in the way of money. Hence it is very important that they should study how to save time and labor to the retailer, and certainly the manufacturers have a good chance to save the retailer much time and also to increase sales by simply putting goods up in a good and attractive manner, and not letting a little extra cost stand in the way of doing so. To prove this I will mention some few things that occur to my mind, as follows:

First.—Paper boxes with metal corners should not be used, because after the cover is taken off it is hard to put it on again.

Second.—Good, strong thin paper should be used to wrap up articles that are packed in boxes of dozens, &c. Most of the paper now used is simply of no use whatever. For example, take a box of Locks, Bolts, &c.; take one out of its wrapper and show it to a customer; then try and put it back in its original shape, and you will find that you will have to get a good piece of paper in order to do so. I would suggest that good Japanese paper be adopted for this purpose, as it is thin, tough, and I believe cheap.

Third.—Manufacturers should refrain from putting printed advertisements with their name and address in goods. This is a feature that many of them have adopted, in fact they do up all articles with regular printed paper that informs a jobber's customer just where the goods are made, also that if he writes direct he can probably get a lower price; if this supposition is not a fair one, why do the manufacturers do it? The jobber has a hard enough time as it is to sell goods at any sort of a profit. So I say leave out the advertisements.

Fourth.—Labels should be printed in black letters on a light-colored paper, the numbers and name of articles in as large type as possible so that a person can read the name at a distance; it will often save running for a ladder to see if you have the article on shelf a few feet up. By all means let the old green and red labels go, and give us new, attractive and readable ones.

Fifth.—Labels should be put on in such a manner that none of the reading matter is hid. Sometimes we have goods labeled in such a manner that one must take off the cover of the box in order to read all of the labels.

Sixth.—This is an age of advancement and improvement, and the Hardware trade are quick to appreciate goods that

are put up in such a manner as to make their stores look pleasant to their customers, and I know of no line of goods that will make the same show as an attractive and clean stock of Hardware. The above remarks refer in a general manner to all Hardware. I will now mention some goods that I believe can be improved on, and in the method of putting up:

DOOR LOCKS

should be tied up with their respective Keys, Escutcheons and parts in a good manner. I sometimes hope that the day will come when each Lock will be done up in a paper box like Night Latches now are.

PADLOCKS

should have their respective Keys tied with good strong twine of suitable length to each lock.

CASTERS

are done up very poorly. Why not put them up in sets and then put them in a wooden box, instead of paper, which breaks and lets out the sockets?

WRENCHES

are very heavy, but most of the makers stick to paper, and very poor paper at that; and at the least handling the wrenches break through the paper and look very unsightly, thus time is lost in putting them in shape again. Let them be put in boxes.

THUMB LATCHES,

blind and gate hinges, blind fasts, &c., are very cheap, but I believe they would bring a better price if they were put up nicely. A clerk could sell one complete without losing so much time in finding all the parts. They should be put up in cheap boxes similar to the way the parts of Torrey's door spring are. In any case, have them so that a set can be sold complete without a clerk having to get a catalogue and studying how many pieces belong to a set.

HAND BELLS

would be much nicer in paper boxes instead of plain paper, as now. They are a nice line of goods and would stand being put up in a convenient and tasty manner.

DOOR BOLTS

should be put up better, so that the nosings and screws do not get lost.

BRACES

should be packed in wooden boxes containing ½ dozen, the better quality in nice paper boxes containing one only; a carpenter will think more of it.

SAWS

should be put up better; the good ones in nice strong paper, covering handle and all, so that the teeth cannot be damaged in handling; the outside boxes are about right.

WOODEN PLANES

are very poorly put up; better paper and nice labels would help a great deal.

AUGER BITS

should be wrapped separately and put in wooden boxes, so as to protect the points and thread.

HATCHETS

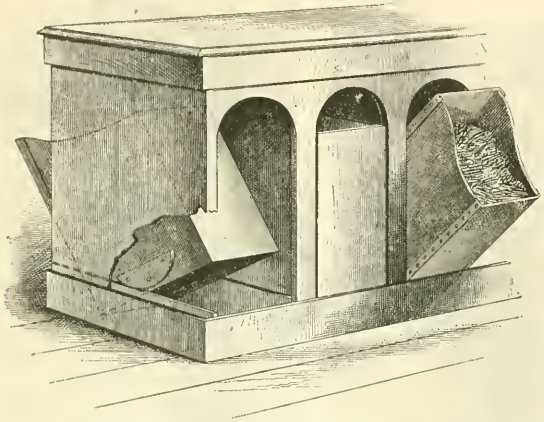
should be put in wooden boxes containing partition for each hatchet, each blade should be well done up in paper. The using of paper boxes in putting up hatchets has caused many a bad cut to the novice in hardware.

AXES,

unhandled, should be put up in paper boxes of one only, with the edge well protected, and the weights marked on each.

ARTICLES

put up in sets, such as chisels, &c., should have the size marked on the paper of each in a prominent manner, this will save time in finding out the size, &c. I could specify many more things, but think the above the most important, as they worry the retailer to a certain extent every day. The manufacturers may complain about the expense, &c., to them, but I believe they can and will in time do much more than I have named in the way of improvements in putting up hardware. I know that corkscrews are imported from Germany at 18 cents per dozen, put up in a real nice strong package, containing ½ dozen only, and we certainly can put up goods as neatly as any nation on earth.



Sheet-Iron Nail Pouches.

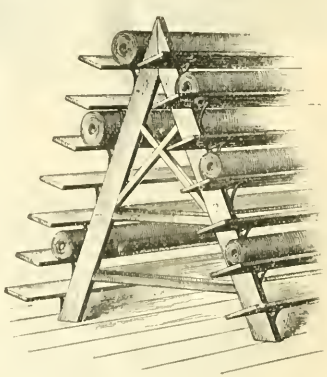
Sheet-Iron Nail Pouches.

We are indebted to H. S. Smith of Miller, Smith & Co., Chadwick, Ill., for a sketch and description of the Nail Pouches shown herewith. The Pouches are made of sheet iron 16 inches high, 16 inches deep and 10 inches wide, having a capacity of a little more than 100 pounds of Nails. They are so arranged that they are self-closing, and Nails can be taken from either side of the counter, or the Pouches can be used under the ledge. The point is made that the Pouches can easily be taken out, cleaned and filled and then be replaced; also that room is economized, as nearly the full hight of the counter is utilized for Nails, thus dispensing with wide bins. In using the old style of Nail bins the company experienced inconvenience from Nails becoming mixed in weighing and putting them back in the bins. This difficulty, they state, is entirely obviated by the use of the Pouches. Mr. Smith is prepared to name prices to any one desiring Pouches or Counters, as they can be put in any counter or under ledge at a limited expense.

Screen Wire Rack.

Wm. Kempf, 2814 Market street, St. Louis, Mo., has made a Screen Wire rack for his own use, as shown in the accompanying illustration.

The width of the roll of Wire is numbered on the front of each shelf and the rack is so arranged as to hold all the different sizes. At the bottom of the rack between the uprights are two shelves which may be utilized for odd lengths of Wire, or for other articles that require but little room. The lumber used in its construction was obtained from window-glass boxes, which of course cost nothing, and the labor was equally inexpensive, as the rack was made at times when there was nothing else requiring attention, so that the entire cost consisted of the nails and brackets, probably about 75 cents.



Screen Wire Rack.

Exhibit of Callahan & Douglas

Callahan & Douglas, Binghamton, N. Y., made an exhibit of goods in their line at the Industrial Fair held last fall in their city, a portion of which is illustrated herewith. The display board reached from the ceiling of the exhibition building to within about 3½ feet of the floor, and filled the entire width of the space at the back. A star of chain was the central figure, within which small tools were artistically arranged. Tools of larger size were grouped with good effect on the board outside the star, showing lines of the various articles. On the floor directly

Exhibit of Callahan & Douglas.

in front of the star was a square formed of gallon cans of mixed paints, in the center of which was a table. Fancy coffee and tea pots were shown on the table. The other goods exhibited in their space consisted of lawn mowers, carpet sweepers, wringers, granite ware, fine builders' Hardware, &c.

Tact in Selling.

In an article containing hints on selling, *Ironmongery* of London gives the following advice to Hardware salesmen, which may be perused with profit:

"It is very bad management to seek to force your opinions on a customer, such as, for instance, trying to get him to take Brown's make of Brushes when he explicitly asks for Smith's; or telling him that Jones' patent Ventilators are defective in principle when he asks for them, simply because what you happen to have in stock are of another make. Most people are inclined to suspect you are not acting honorably with them if you should seem to press them to take a different article to what they inquired for; much better is it to tell them candidly you do not stock Brown's brushes or Jones' Ventilator, but will procure them specially, at the same time showing what you do keep, without appearing to push them. But when a person does not specifically ask for a certain make of goods, you may unobtrusively influence him to take that of which you have a large stock, or which, for some other good reason, you would rather sell. It is much more satisfactory, both to your employer and your customer, that where you find you can use your influence over the latter you ought to get him to take a good reliable article rather than one of the description popularly known as "cheap and nasty." Many a purchaser will actually seek the advice or opinion of the assistant who is serving him as to the merits of the article he is buying, and rests quite satisfied with the answer. It has often occurred to me that to correctly reply to all the questions asked by those who patronize an ironmonger's shop an assistant must needs be a walking encyclopædia. How to fix a Gas Pipe or an Electric Bell, how to replace an old Sash Line with a new one, how to clean a Silver Teapot or a rusty Range, the best way to use a Plane or an Axe, a Digging Spade or Garden Shears; the most appropriate color of Tile to suit this Grate, or the most suitable Knocker for that door; these and many others are repeatedly asked, and the assistant who fails at any of them is placed rather awkwardly, as the customer is likely to lose faith in his ability if he betrays his ignorance of the matter under consideration. It were much better for an assistant to remain silent rather than talk on a subject in which he is not sufficiently informed, for it is not unlikely that the customer may be thoroughly conversant with it, and an attempt on the part of the former to describe that of which he is ignorant can only result in the latter setting him down for an ignoramus all round.

A correspondent of *Le Génie Civil* of Paris deals with the question of handling mortar in frosty weather. Having tried mixing alcohol and sea-salt with the water, he has now adopted common soda, which he finds gives the most satisfactory results in preventing the freezing of the mortar. One pound of soda is used to a gallon of the water with which the mortar is mixed, and the increased cost is reckoned to be about 18 cents per cubic yard of masonry, an outlay which it is often well worth incurring to avoid the loss and delay incident to stoppage of work in frosty weather. The use of the soda causes an efflorescence in the walls of the building, but the blotches thus arising are said to entirely disappear in the course of a short time.

Price-List and Circular Case.

The views shown in Figs. 1 and 2 represent case used by Geo. Krause & Co., Lebanon, Pa., for keeping small

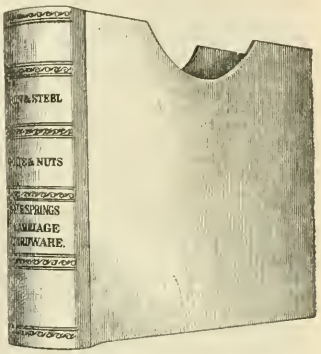


Fig. 1.—Price-List and Circular Case.

price-lists and loose circulars which it is desirable to preserve, and yet are difficult to keep in a convenient form for ready reference. The cases are bound in leather and cloth, of different colors, with lettering on the back describing the contents, which when put on a shelf side by side make a fine appearance, and re-

Fig. 2.—Appearance of Case on the Shelf.

semble to a marked degree a set of volumes. The most desirable size for these cases has been found to be 9½ inches high, 14 inches deep and 3 inches thick. F. W. Frost of Lebanon is the manufacturer, who has also made others for parties who have seen these at the above store.

STOVE TRADE NOTES.

Electric Heaters for Street Cars.

Tests have been made during the past winter by the Albany Railway, an electric line, says our Albany correspondent, which demonstrate the success of the electric heater manufactured by the Consolidated Car Heating Company of that city.

The inventor of the electric heater is James F. McElroy, consulting engineer of the Consolidated Car Heating Company. The method of transformation of electric energy into heat employed is by the passage of an electric current through a resisting conductor. In the construction of this heater the resisting conductor is divided into a number of parts, so that these parts may be assembled in different combinations, offering different resistances to the passage of the current, and thus obtain different intensities of heat. For convenience the resisting conductor on each car is divided into 12 equal parts, two of these parts being combined into one heater, so that six heaters are placed in each car. The resisting conductor wire is coiled in the form of a close and continuous spiral. A cylindrical glazed porcelain insulator is provided, mounted upon a ⅝-inch square iron rod. A spiral groove is formed upon the surface of this cylindrical porcelain insulator, and extends continuously from one end of the heater to the other. The resisting conductor is placed in the spiral grooves after being drawn out sufficiently to prevent neighboring coils of the spiral from coming in contact with each other.

At the end of each division of the heater a glazed porcelain plate is provided in which binding screws are placed, to which the ends of the spiral are connected. The two parts of the resisting conductor placed in each double heater are separated by a glazed porcelain plate so that the parts may be connected independently where the plan of wiring so requires. The spiral resisting conductors are placed on the porcelain insulator, which is supported by an iron rod, and carried at the ends of the heater upon two cast-iron supports. By these supports the heater is fastened to the floor of the car, and these supports also furnish the means of securely attaching the covering box of the heater itself. All parts of the apparatus are thoroughly insulated. A peculiar construction removes entirely the dangers of short-circuiting.

The heater is covered with an ornamental wooden box, which is lined throughout with asbestos mill board, in which is made a screened opening through which the circulation of air from the heater is maintained.

The heaters are so placed as to distribute the heat within the car as evenly as possible. The electric heater warms the car by indirect radiation; in other words, a free circulation of warm air is maintained in which the air flowing in at the bottom of the heater comes in contact with the heated wire spiral and with the porcelain insulators. It then passes up through the casing and out at the grated opening at the front of the heater. One of the most commendable features of this electric heater is its cleanliness.

As to the cost of heating a car with the electric heater, it is evident that the cost must be calculated by the quantity of current consumed. As this quantity varies with the variable electro motive force carried on most street car lines, it is evident that the actual electric energy consumed is a matter not readily determined. On most street-car lines the total cost of an ampère-hour on a 500-volt circuit is about ½ cent.

The electric heater is also made in a variety of forms especially adapted for house and office service and is so wound, if desired, that it can be used with any voltage and with either a direct or alternating current. The new heater is the result of six years' of practical experimenting by the inventor. The company expect to fill many orders for them during the coming summer.

Alaska Poker Patent Sustained.

The stove trade of the country will be interested in learning that the Troy Nickel Works of Troy, N. Y., have finally succeeded in securing their patent rights relative to the Alaska poker. The action by John E. Gaitly against Frederick W. Collins was brought in the United States Court to recover damages on account of infringement by the defendent of letters patent No. 381,356, issued to Mr. Gaitly on April 17, 1888, for certain improvements in fire pokers. A large amount of testimony was taken in the case and a great many old patents introduced in evidence. The case was heard before Judge Wallace on January 17 of the present year, at a regular term of the court held in Albany, and a decree entered declaring the validity of the said patent and ordering an injunction against the defendant, which was issued by the court named on January 20, 1893. As being of possible interest in this connection we present below a copy of the decree in full.

The President of the United States of America, to Frederick W. Collins, and to your agents, clerks, servants and workmen, Greeting:

Whereas, It has been represented to us in our Circuit Court of the United States for the second Circuit of Northern District of New York that letters patent of the United States were issued to John E. Gaitly in due form of law, on April 17, 1888, for improvements in fire pokers, said letters being known as No. 381,356, and that you the said Frederick W. Collins, have infringed said letters patent and upon the exclusive rights of the complainant under the same, contrary to the form of the statute in such case made and provided.

Now, therefore, we do strictly command and enjoin you, Frederick W. Collins, your agents, clerks, servants and workmen, under the pains and penalties which may fall upon you in case of disobedience, that you forthwith and forever desist from directly or indirectly making, constructing, using, and vending to others to be used, fire pokers containing or employing the invention described and patented in the said letters patent No. 381,356.

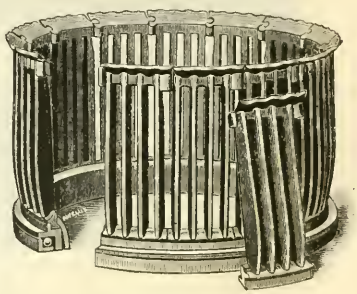
Witness, The Hon. Melville W. Fuller, Chief Justice of the Supreme Court of the United States at the City of Utica in said Northern District of New York, this Twentieth day of January, in the year of our Lord one thousand eight hundred and ninety-three, and of our independence the one hundred and seventeenth.

W. S. DOOLITTLE, Clerk.
By C. W. HIGGINSON, Deputy Clerk.

A True Copy, W. S. DOOLITTLE, Clerk.
By C. W. HIGGINSON, Deputy.
[SEAL.]

The Ridgway Revolving Open Fire Pot.

One of the interesting features in connection with the construction of the Ridgway heater, manufactured by the Ridgway Furnace Company, Boston, Mass., is a revolving open fire pot, a view of which is presented in the accompanying illustration. This fire pot is claimed by the makers to embrace improvements which overcome the defects of both the cast iron and brick-lined pots, maintaining and excelling the advantages of the two. It is made in sections and put together in such a manner as to allow for expansion and contraction, besides facilitating handling in shipment and setting up. It is revolved on balls about 1 inch in diameter, bearing on perfectly flat surfaces, resulting in the least possible friction. The construction is such that any of the working



The Ridgway Revolving Open Fire Pot.

parts can be removed or replaced without taking the furnace down or disturbing the hot-air pipes. The manufacturers state that "with the use of this revolving open fire pot the entire surface of the radiator is utilized by the direct radiation from the sides of the burning fuel, as well as from the top, for the products of combustion not only pass upward but outwardly through the open spaces in the sides, burning the gases near the radiator as fast as generated, thereby utilizing them to the greatest extent and preventing explosions, which are likely to occur in furnaces constructed with the ordinary fire pots." Reference is also made to the advantages of this pot in running a continuous low fire, for, being surrounded by a plate iron radiator, it permits of direct radiation from the sides of the fire, while preventing the cold air from coming in contact with the sides of the pot and thus chilling the fire. The fire pot is revolved by means of a crank placed at convenient hight, so that there is no necessity of stooping over to shake the grate. The contents of the pot adhere to the sides, turning with it, and as the grate remains stationary it scrapes the ashes from the fire without packing the coals, as is frequently the case when shaking the grate. This plan, the makers state, allows the operator to graduate to a nicety the amount of ashes to be cleared, according to the heat required. Provision is made to remove any ashes which may fall through the sides of the fire pot by means of a plow

or scraper placed in front, and which clears the bed plate on which the fire pot rests every time it is revolved.

The Ridgway heater, in connection with which this open fire pot is employed, has a radiator or dome made of the best refined plate iron, strongly riveted. From this the products of combustion are carried down to a return base flue, through two heavy sheet iron oval pipes, one on either side, and from thence upward through a similar pipe at the back of the radiator and discharged to the smoke flue. One of the special features to which attention is invited in connection with this heater is that the return base flue is separate from the ash pit, allowing the air to circulate between it and the main body of the furnace as well as to pass its outer surface, which, it is claimed, supplements the heating qualities of the furnace. The return base flue is suspended from elbows at the top of the radiator by means of heavy iron rods. By this means the base flue rises and falls with the radiator as the latter expands or contracts and without disturbing the joints where the perpendicular flues enter. Another interesting feature of the Ridgway heater is the direct draft damper, which is so constructed that there is no connection between it and the hot air chamber. The arrangement is such that by a simple device the damper opens and closes automatically each time the feed door is opened or closed.

New Trade-Mark.

The Detroit Stove Works have adopted a new trade-mark, which is herewith illustrated. This is the outcome of the numerous designs for a trade-mark submitted to the company in response to their advertise-

New Trade-Mark of the Detroit Stove Works.

ments last fall, in which they offered a prize for the best. The successful competitor has certainly produced a very effective piece of work for a trade-mark. It is distinctive, pleasing and simple. The outlines are of such a character that the trade-mark can easily be reproduced in any manner—printed, stamped, embossed or molded. Wherever seen it will be recognized as the peculiar emblem of this company. Being in the form of a crown, jewels are naturally suggested, and therein comes the special connection with the Jewel line of stoves and ranges manufactured by the Detroit Stove Works. The scroll at the bottom marks a departure from the custom in vogue of making it the place for an extravagant claim, the words inserted being: "The Original Detroit Stoves," forming a legend which is at once truthful, dignified and historical.

At the Philadelphia house of Yeager & Hunter of Spring City, Pa., Elwood Yeager shows samples of the Queen New Era, the new range which will be the leader of their cooking line for this year. Its beauty and quality are too striking to require a great deal from the genial manager to convince the trade that it is indeed a Queen.

Care of Vapor Stoves.

A little pamphlet of 12 pages has just been issued by the National Vapor Stove & Mfg. Company, in which is given a number of directions for the care of vapor stoves. The matter is of such a character that it cannot fail to interest many of our readers, and we therefore present copious extracts herewith:

Our aim in printing this little book is to give such information to the users of our stoves as will enable them to understand any peculiarity that may arise at any time in its workings. A vapor stove is not a very complicated piece of workmanship, nor does it require any unusual amount of brains to understand, but it is positively necessary that when in use its working parts must be kept clean and free from soot. This is the root of all trouble with gasoline stoves. The users will allow soot and dirt to accumulate on the burners, thereby making them work very indifferently, if not positively stopping the operation of the entire stove. A broken part on a stove must be repaired or replaced by a mechanic, but there is no good reason why the cleaning of a stove cannot be done by any person.

The burner is the main feature on a stove, as this part does all the work; the rest of the stove has nothing to do with the generation of gasoline, but merely takes care of the gas after it is generated.

A hard coal base burner is all right when the fire pot and drafts are in good condition, but if these two very necessary things are out of whack, the stove is of no account, no matter how nicely it may be nickel plated.

The same thing applies to a gasoline stove. Burnishing up the top and nickel-plated parts does not make the stove work if you do not clean the generator.

We make these few remarks on the care of a gasoline stove, knowing that the troubles arising from these stoves are not from any parts wearing out, but generally on account of users allowing the generators to get dirty and interfere with the workings of the generator.

Where a stove is used in a city it does not matter very much whether the stove does occasionally get out of order, as a man to repair same can be had at a moment's notice, but where these stoves are used in the country, or where they are the only cooking stove in the house, and we might add that gasoline stoves are fast becoming the only cooking stove where families have the kitchen heated by a furnace, it then becomes a hardship to have the stove give out just as you are depending on it as the only factor for cooking your meals.

The average user of a gasoline stove is supremely contented as long as the stove works nicely and does good cooking and baking, but as soon as some little obstacle arises to mar the smooth operation of the stove they become disgruntled and are prone to find fault with the stove, but never for a minute do they believe it may be possible that the trouble can be traced to their own carelessness. But such a thing is the case nine times out of ten. Carelessness in the care of a stove is the paramount cause of 90 per cent. of the dissatisfaction arising from the poor workings of any stove.

NOTE THE FOLLOWING.

Use only the best grade of gasoline; 74° test is the proper kind to use.

If you use bad gasoline your burners will soon become coated with soot.

Always fill the reservoir in the morning, and not too full. Never attempt to fill reservoir near an open fire or light, as the gas is liable to catch.

Never use a funnel or measure that has been used for coal oil, or any other oil; use a measure or vessel for that purpose only. The least trace of oil in gasoline is enough to make the burners smoke. Avoid allowing water to be mixed with gasoline, and never attempt to clean out the pipes with water or oil. When you have water in the pipes of your stove it may or may not be noticeable, as it would all depend on the quantity as to whether it would affect the workings of the burner. Should there be any quantity the burner would go out while you were using it, without any apparent cause, and could not be lighted again until all the water was taken out. To do this unscrew the plug at bottom of burner and drain the pipes, then put in pure gasoline.

Should the valve leak at the stuffing box tighten with a wrench. It is expected that every stove will leak at this packing nut after it has been used awhile and the packing has become hard. It is impossible to tighten it sufficiently at first to keep it from leaking after it has been used; but as it only takes one-half minute to tighten it up it should not be called a defect. If by tightening the stuffing box does not stop the leak repack stuffing box with some packing, for it becomes worn out around valve with constant use and hardens with heat—so hard that it will not close around valve without repacking.

KEEP THE BURNERS CLEAN.

This is the one great crying necessity on a gasoline stove. It must be done or you have trouble. Cleaning a burner takes so little time each week that there can be no excuse for any one so misusing a stove as to cause any trouble from this quarter.

Soot accumulates on the under side of the generator from repeated lighting up of the burner, and this soot adhering to the brass prevents the flame from heating the burner quickly, and sometimes you will have to fill the cup two or three times before you get the burner hot enough. Now all that is necessary is to take the end of a match and scrape the soot off. Some people use an old whisk broom or the wing of a fowl especially for this purpose.

Soot also forms on the needle point from the same cause as described above, and the stove will then burn a very yellow fire when only one or two burners are being used, but when more than two burners are being used the flames are entirely blue, as if nothing ailed the stove. This point is very easily explained, as the soot forms on the end of the needle, and when you open the valve sufficiently for one burner this mass of dirt partially closes the opening and the fire is yellow and lazy; but as you turn on more vapor this accumulation on the needle recedes into the burner and leaves the opening clear, so that it works as if nothing were wrong with it.

When generator fire burns yellow or has yellow points darting up through the flame, you will know that the needle valve needs cleaning. To clean the needle is but a very short task, and if done occasionally will give as large and perfect flame as when the stove was first used. The manner of cleaning the needle is to first close valve on gasoline tank, so that the fluid will not flow, then unscrew packing nut, then unscrew needle valve, take the needle valve out through the hole in name plate, using care to not dull or bend the needle point, then clean the point carefully and replace as before, and you will find in nearly every case that this is all that is required to make a perfect flame again.

CLOSING VALVES.

In shutting off the burner avoid at all times closing valve too tight, as through expansion of the brass you are liable to

enlarge the orifice at needle point and thereby cause burner to leak the next time it is shut off.

There is no need in using force in closing off the valves on any one of our stoves, as you do not make matters any better by jamming the needle through the orifice every time you shut off the burner so as to be sure that it will not leak, for that is the very way to start a leak. Use ordinary common sense in shutting off a valve, for when the supply is shut off an extra twist on the valve is not going to help matters or make anything more secure.

LEAKS.

A leak at the needle point is remedied by taking out needle valve and setting check nut back just a little, so as to let the valve seat itself a little deeper. Where the check nut is exposed, as it is on Junior and some individual burner stoves, take a wrench and set it back without taking valve out of the burner.

A leak at the swivel joint, where tank turns down to be filled, can be remedied by loosening the set screw and tightening nut with a monkey wrench. A leak at the thread, at any part of the stove, can be stopped by taking out the parts and rubbing common brown soap on the thread and replacing as tight as you can. Gasoline does not affect common soap.

GASOLINE.

There is an unwarranted prejudice and fear existing against the use of gasoline that is entirely unfounded and which cannot be truthfully sustained by facts and evidence. The common theory advanced is that gasoline is explosive and consequently dangerous; but this is not the case. It will not explode; it never did explode, and no one can explode it, let them try it ever so long. It is, like so many other things, perfectly safe in safe hands, but more or less dangerous in dangerous, ignorant or careless hands. People who use it should inform themselves of its character, so that they will know how to handle it safely and know wherein its safety or danger lies. The liquid, in a can, tank, barrel, or, in fact, any form, is positively non-explosive, and the vapor escaping from a can with the screw top off, in an ordinary closet or living room, can positively do no harm; but, when agitated in drawing or filling a can or reservoir, considerable vapor escapes, and this vapor is capable of taking fire a little distance away from the vessel, and this is where the dangerous part comes in. It should never be handled near a fire or light, as the vapor is heavier than air and always descends. Never fill a stove when burning, nor fill it full to overflowing before lighting.

Where a gasoline stove is only used in the summer time, it ought to be stored in a dry place, as dampness will rust the working parts of the burner and render them unfit for use.

The little lid between the twin burners, on the New Idea stove, is simply to assist the user. If at any time sediment should accumulate on the point of the needle, it can be lifted up and cleaned off.

STORING GASOLINE.

Keep the can or barrel of gasoline where there is a good circulation of air—never in a cellar.

Gasoline vapor is heavier than air, so much so that it descends to the lowest point and there accumulates.

The above thoroughly explains the cause of all of the accidents that ever befell a user of a gasoline stove.

Gasoline never freezes, and will give off a vapor at zero.

Years ago, when the old style stationary tank was the only kind of reservoir used on a stove accidents were numerous, caused by the utter disregard of the printed instructions on the reservoir—(Do not fill while burning)—but in spite of this warning, people would attempt to fill the reservoir without putting out the fire, should they find that the gasoline in the tank was giving out and the meal only half cooked.

A gasoline stove explosion would be recorded in the daily papers the next day, when, in fact, the material only caught fire. The saddest part of these affairs was that generally the user would get burned, in many cases fatally.

The stoves for the past few years have been made with a safety device in the shape of a drop tank. By the use of this tank the fires must be put out, for the reservoir cannot be filled until it is laid down on its side, and this very act puts out all burners.

These stoves are manufactured and sold at the rate of 250,000 a year, attesting to their utility as a labor saving utensil.

BURNERS PUFFING.

Should your burners puff or oscillate it shows that the gasoline is being fed too fast, and if you will regulate the flow with the valve at the reservoir or with the pug valve in the T underneath the burner it will affect the operation.

When the needle valve is first opened if the gasoline does not flow at once give it a little time, as there may be air in the pipes.

When the stove is first started in the spring and all the gasoline has evaporated out of the reservoir and pipes this trouble will be experienced, and the quickest way to get gasoline to run to burner is to unscrew reservoir and allow gasoline to trickle down in the pipe by turning on the valve at bottom reservoir.

The burner must be allowed to become thoroughly hot before using. If this is done and the general rules on direction cards sent with each stove are observed we guarantee perfect success.

It is always better to give a burner plenty of time to heat than too little.

BURNER CAPS.

It often happens that the slots of the burner caps are closed up by stuff boiling over on the burner while cooking. Should anything like this happen to your stove you should take a small wire, hammered flat at one end to fit slots, or a piece of tin of right thickness, and clean the slots. In fact, it would be a good idea to have a small wire handy and clean the slots every week.

CLEANING STOVE.

A gasoline stove should be cleaned in the spring without a doubt. It may run for several seasons without absolutely demanding a cleaning, but to insure a freedom from annoyance it ought to be cleaned in the spring, and then it will be in shape for use all summer.

If you do not use your gasoline stove during the winter months it should be stored in a dry place, so that the valves will not rust.

There are some parts on a gasoline stove that are as finely made as a sewing machine, and no one would think of putting the sewing machine out in a shed.

In the spring, when you are ready to use your stove, you should take it out in the open air and take out all the plugs, especially the plug that covers the end of pipe, then let about a gallon of gasoline flow through and wash out any sediment that may have accumulated in the pipes from the previous summer.

You should throw away the gasoline you use in cleaning and do not attempt to use it in the stove.

Our stoves are all tested for leakages or imperfections before shipment.

The full power of a burner is seldom required. Good results and better economy are secured by the flame being turned down a little. In preparing for baking it is necessary to heat your oven for about 15 minutes before you place the baking in it.

If there is any need to take the pipes or burner apart rub common hard brown soap on the threads before screwing them together.

If a gasoline stove is kept clean, it should never cause any trouble.

Never close the tank valve while the generator is hot, as the pressure from the generator is apt to force a leak in burner joints or pipes.

The slots of the caps on the stoves are sawed by the same sized cutters, and where the iron is of even quality the slots are of uniform size; but, in cutting, if the saws should strike a hard spot in the cap it would heat them and make them cut a larger slot than usual. We inspect these caps before they are put on the stoves, but despite this precaution a large slotted one will find its way on a stove. The slots of these caps must be of a certain thickness to give the required flame. If too small, a dull fire is the result; if too large, the flame will catch back inside the cap when it has got superheated. When this occurs, it blows out all the burners and flame slows at needle point. A perfect cap is the only remedy.

ODD PLATES.

The Wrought Iron Range Company, St. Louis, have secured the contract from the Epworth Hotel, Chicago, Ill., for one of their Home Comfort ranges, which will be 30 feet long. In addition to the range they will also supply all the culinary apparatus used in this hotel kitchen, which, as a glance at the size of the range will denote, will prove considerable.

Notice is issued to the trade, under date of April 6, by the Standard Pattern Works, Cleveland, Ohio, William Battensby, proprietor, that he has sold out his business to William M. Gobeille, the sale including tools, stock, business, good will and friendly services. Mr. Gobeille will remove everything to his four story building on West Center street.

Charles J. Ridgway, secretary of the Ridgway Furnace Company, Boston, is making a Western trip, showing the latest pattern of Ridgway furnace, which was recently awarded a gold medal at the exhibition of the Massachusetts Charitable Mechanics' Association. The latest agencies for the sale of these furnaces are the Isothermal & Plumbing Company, Philadelphia, Pa.; M. E Rowe & Co., Chicago, Ill.; B. A. Weber, Rockford, Ill.; Ramsay & Lerdall, Madison, Wis.; and F. Shriver, Sr., Grand Rapids, Mich.

Uzal Cory & Co., 210 Water street, New York, were lately the recipients of two curious orders for goods of their manufacture; one destined for the North of Ireland and the other for northern China. J. Galt Smith, a native of the green isle, divides his time about equally between New York and Larne, a town in the County of Antrim, situated on Larne Lough, an arm of the North Channel. Having lately inherited Kilwaughter Castle, located at Larne, he concluded to import an Excelsior Gas-Tight furnace to supplement the heat now furnished by open fire places in the various rooms. The main hall of the castle is 70 feet long by 30 feet high and the same in width. From this hall there is a broad staircase branching right and left to galleries leading to suites of apartments on upper floors. It is not known how long this structure has existed, but two or three centuries ago it was used as a monastery. Its foundation walls are said to be 17 feet thick, diminishing to 8 feet higher up. The cellar division walls are 4 feet through. The building is surrounded by the usual moat and crossed by a drawbridge. The shipment

aggregated nine boxes, being shipped to Belfast via Liverpool by the Cunarder "Servia," sailing April 8. The necessary pipes and registers, together with working plans to assist in the proper setting of the apparatus, accompanied the shipment. The heat will be thrown from four large pipes on the lower floor only, and is merely intended to supplement the present facilities. An interesting feature in connection with the castle is the capacity of the chimney or smoke flue, which, owing to the large use of soft coal, requires cleaning at least once a year. This flue starts from the cellar and after rising about 20 feet makes a turn at right angles between the ceiling of one room and the floor of that above, traversing a distance of 15 feet, when it again rises. An old retainer has for many years had the privilege of cleaning this flue, receiving the resultant fee, while more recently the work has been done by the son and grandson, though the fee has been retained by the old gentleman. The other shipment is for W. R. Faries, M. D., Wei Hein, Chefoo, China, not far from Pekin. This is a similar furnace of a smaller size, making seven boxes, including the necessary pipes, registers, &c., and is intended to heat a ten-room modern house recently built.

THE CENTURY STOVE COMPANY, Dighton, Mass., are pushing the Century range, for which they claim several points of superiority and the additional attraction of a moderate price. George L. Walker, treasurer, has just returned from a Western trip in the interest of this range.

WALKER & PRATT MFG COMPANY are now re-established at 31–35 Union street, Boston, from which location they were driven out by fire a short time since.

THE SAN MARCO FLATS, which have recently been erected on the southeast corner of Madisonville and Woodburn avenues, East Walnut Hills, Cincinnati, Ohio, are being furnished with Burton's Favorite gas ranges. These stoves, as our readers are aware, are manufactured by the Cincinnati Steel Range & Furnace Company of 158 West Fifth street, Cincinnati, Ohio.

FAITH, BELSON & Co. are preparing to keep pace with the demands made upon them by patrons who appreciate good service. They are having alterations made at 229 Market street, Philadelphia, to suit their needs, and will have a greatly increased space, as the building runs through to Church street, near their warehouse. Every effort is being made to fill orders as they are presented previous to their removal to their more convenient quarters, which will be about June 1.

DURING the four years the Kelsey corrugated warm air furnace has been on the market the manufacturers, the Kelsey Furnace Company of Syracuse, N. Y., state that it has been subjected to crucial tests, which in every case it has stood with entire satisfaction. A feature of this furnace is the fire pot, which is of such a durable character that the company state they have had occasion to replace only a portion of a single fire pot which proved defective, and that clearly was in no sense a fault in the construction of the furnace. This is a record of which the makers feel justly proud, more especially since severe criticisms have been made respecting this essential feature of their furnace.

A FLYING VISIT to Philadelphia has just been made by W. McK. Barbour, the treasurer of the Boston Furnace Company of Boston, Mass., who is preparing to meet the demands of the stove trade in New England with satisfaction in every particular.

THE ILLUSTRATED DESCRIPTION of an old heating stove which appeared in these columns April 8 has called out a letter from G. L. Morrison of the J. L. Mott Iron Works of this city, who states that the stove was made by his grandfather, John Morrison of Troy, N. Y., who owned and built the Green Island Foundry, sold some years ago to M. L. Filley.

THE KEELEY STOVE COMPANY of Columbia, Pa., have issued a catalogue for 1893, illustrating their stoves, ranges and furnaces. In addition to the line of goods so well known to the trade, the company illustrate their new portable horizontal boiler range, Columbian Newport, six holes, high and low closets, with ash sifter and open bottom for the dropping of ashes into the cellar when desired, and large swelled oven door with patent opener; also their new range, Columbian Charm, a six hole range of very handsome design constructed on the double-heater principle, with feet and skirting, reservoir, and cosy high closet. As a novelty they introduce the Columbian Chime double heater fire-place stove, which they claim to be particularly applicable for use in a library, sitting room or parlor. In design it is highly ornamental and would no doubt prove to be a very economical combination with furnace and hot air heating. A few seasonable remarks on their general line, a few words to customers on the subject of repairs for stoves and some valuable rules regarding sales help to make it a most interesting book. It appears in a handsome lithographed cover, and is printed in plain type on good paper.

THE WROUGHT IRON RANGE COMPANY, St. Louis, Mo., will increase their capital stock from $500,000 to $1,000,000.

HARRY MCDOWELL has just returned from one of his spring trips for the Leibrandt & McDowell Stove Company of Philadelphia. He reports some good sales of gasoline stoves and an outlook for regular goods later on that evidently is pleasing.

THE CHICAGO & ERIE STOVE COMPANY, Erie, Pa., favor us with circulars of their Superb Helper hotel range, which has just been placed upon the market. It is a heavy construction lined with asbestos and having both front and end draft slides. There are also provided heavy brick linings for hard coal and cast linings for soft coal. An interesting feature of construction is the patent cast braces and asbestos heat reflectors under the oven, the advantages of which are obvious to the trade. The grate is plain and heavy, the arrangement of parts being such that a poker can be inserted through the drop door in front and be passed over the grate bars, while a hooked poker can be inserted under the grate and between the bars therein. By this means the grate can be easily cleaned above or below. The size of the top plate is 4 feet 8 inches long by 31 inches wide, while the eight boiler holes are each 9 inches in diameter. The oven measures 29 inches long by 22 inches deep and 16 inches high. The range is an attractive one and the manufacturers are confident it will meet with a large sale.

FROM THE ABRAM COX STOVE COMPANY of Philadelphia is received a 16-page pamphlet of fine typographical display, in two colors. On the first cover, on a white ground surrounded by a buff tint, the Ideal Novelty, in bright red, greets the eye and introduces their new line of hot air furnaces and combination heaters, while the back cover is occupied by their familiar trade-mark. From the opening paragraphs it is learned that this line is the culmination of the experience of a half century and is indeed an "Ideal" line, comprising six styles and 28 distinct furnaces. Then follow illustrations showing the portable and brick-set styles and a view of the grate and fire pot, an interior view of the combination heater and the hot-water section, which is cast in one piece, so that leaks are impossible and its lasting qualities insured. One form of furnace has their arrangement of steel drums adapted for either hard or soft coal, while of another, in crimson display, they say, "We recommend this for soft coal," and illustrate an all cast iron furnace. The description is brief, terse and comprehensive, well displayed, and from it it is learned that the parts are widely interchangeable, so that the cast-iron radiating section for soft coal can be substituted for the steel dome or the hot-water section in either the portable or brick set form. Their claims for efficiency and durability are followed by "approximate ratings," which are based on experience and safely correct. Some sensible suggestions are given in an observation here that "a furnace too large is infinitely preferable to a furnace too small," and that "a furnace too small burns more fuel, wears out sooner, and requires more attention than a furnace too large."

THE NEW YORK GAS STOVE COMPANY of 242 Sixth avenue, New York City, have just gotten out a catalogue of 16 pages relating to the Economy gas cook stoves, manufactured by the American Meter Company of New York and Philadelphia. These goods are shown in several varieties, a new design of stove having a closed top, while the baking and roasting ovens are fitted with new and powerful burners. The hot plate is 31 inches wide and 22 inches deep, and has five boiling burners, together with a central pot hole for keeping vessels warm with the heat from the roasting oven or the boiling burners. The openings on top are fitted with rings, which may be removed to increase the size of the opening. Some of the cuts show the stoves with the doors open, thus exposing the interior of the ovens. Wire gauze ovens are illustrated, as well as Economy table stoves, ranging from one to three burners. The last page of the pamphlet carries a number of directions for using the Economy stoves.

WILLIAM THOMSON, the affable manager of the Philadelphia house of Orr, Painter & Co. of Reading, Pa., is making a trip among his friends in New Jersey, apprising them of things that will appear later on, which will continue the Sunshine season into the early winter.

THE STOVE FOUNDRY of Z. Hunt, Hudson, N. Y., resumed operations on the last day of March, after having been shut down for some time. Mr. Hunt anticipates, we understand, a busy season, and will give employment to a large force of hands.

THE PHILLIPS & CLARK STOVE COMPANY of Geneva and Troy, N. Y., have added to their force of traveling salesmen Frank Powers, who will represent the company in Northern New York, Vermont and Massachusetts. The manufacturers state that the quality of the Andes stoves and ranges will be fully sustained the coming season and the assortment increased by the addition of several new and improved patterns.

IN AN INTERVIEW with a representative of the *Journal*, published at Lewiston, Maine, Superintendent McFadden of the Auburn Stove Foundry Company of Auburn, Maine, states that they are manufacturing 140 different sizes and styles of ranges and stoves, the Royal Falmouth taking the lead. The company are said to have about 250 agents in the New England States. In some of the cities the agents carry a full line showing the different styles and are meeting with good sales, the latter being the largest where the goods are the best known. Mr. McFadden is represented to have expressed himself as follows: "Some agents have a few goods made by several different

manufacturers and sell very few of each kind. It is natural for the manufacturers to be anxious to sell as many goods as possible in the place where they are manufactured, and when unable to find local dealers who will put in a full line, it is for the manufacturers to open a store where all their particular make of gooda can be shown to advantage. In such cases it is intended that the store be used for wholesale and retail purposes, and that the city in which this store is located is the only store in which the company carry on a retail business. This plan is followed in many New England cities and towns where manufactories are located."

F. SABIN, 146 North Second street, Philadelphia, displays a handsome photograph of the French Fortune range made by the Thomas-Roberts-Stevenson Company of Philadelphia, which is one of the new additions to their excellent line of kitcheners. It affords all of the facilities of a French range at an attractive cost. The range shown has a double oven, a low closet and a planished steel hot closet. The top is finished in French style and has three square plates with covers and rings of varying diameter. One of these plates can be removed and others can be made to slide along on the frame of the top when required.

A PUBLIC EXHIBITION was recently made in London of the practical application of electricity for cooking purposes. The stove provided very much resembled an ordinary gas-burning construction, with various patented appliances for broiling, baking, &c. The heat was produced by sending an alternating current through a network of fine resistance wires embedded out of sight in the side of the stove. It was stated that a small stove required about 12 ampères of current per hour, but that larger sizes were more economical. The demonstration was made before an assembly of ladies who had gathered to listen to a discourse on "nelected points of domestic hygiene."

THE J. F. PEASE FURNACE COMPANY state that their store at 75 Union street, Boston, Mass., will be hereafter used as a depot from which the New England trade will be supplied on short notice with Economy furnaces and heaters. The company have decided on account of the rapidly increasing business to dispose of their retail stores in New York and Boston and to offer the plants in these cities for sale. The wholesale trade, however, will be cared for as heretofore and the store in Boston will be devoted to the purposes noted above.

A VISIT to the Builders' Exchange on Seventh street, between Market and Chestnut streets, Philadelphia, affords the stove dealer an excellent opportunity for contrasting the merits of many hot-air furnaces and kitchen ranges, which are here grouped and shown to the best advantage.

A. WEISKITTEL & SON of Baltimore, Md., are distributing a neat catalogue of something over 30 pages relating to their Fire King stoves. The goods shown include ranges, heaters and ovens in great variety, and are illustrated and described in a manner likely to interest the trade. Among the novelties to which special attention is invited may be mentioned the company's patented burner, which is constructed of two heavy pieces of cast iron, held together by their own weight. The arrangement is so simple, it is claimed, that any child can lift the top off and clean the burner. The company's gas ranges are provided with oven lighters, by means of which the oven burners may be lighted without opening the oven doors. The ranges also have a pedal attached to the front, by which any of the oven doors can be opened by the simple pressure of the foot. The catalogue is printed in two colors, and is bound in paper covers, the front one carrying a picture of the Fire King gas ranges in operation.

A BURNER for oil heating or cooking stoves forms the basis of a patent granted to E. M. Wright, Buffalo, N. Y. The feature claimed in this invention is a combined steam and flame spreader, consisting of two shells so secured together as to leave open spaces between them. The circumference of the upper shell projects beyond the edge of the lower shell, while around the periphery of the latter is a series of openings. Projecting downward from the lower shell is a tubular portion for the purpose of connecting with the water wick tube. The wick is inclosed with a wick tube, which surrounds a water vessel, and connected with an oil reservoir. The arrangement of parts is such that the flame of the burner is directed toward the spreader, and the steam rising from the wick tube is conducted from the water wick tube to the steam and flame spreader and superheated, and from thence is carried into the flame. There is also provided a copper rod which extends down through the water wick for the purpose of conducting heat thereto.

INCREASING POPULARITY is reported by Geo. L. Flick of 141 North Front street, Philadelphia, for his ship stoves, the Ocean Gem and Caboose No. 2, since the recent changes in their tops. Round holes can now be furnished, permitting the use of cooking utensils such as can be procured in any port.

IN HIS VISITS to the gas stove trade, J. Slatterly, representing Luther & Lederhos, 30 Cliff street, New York, finds a pleasant interest in the different gas stoves and appliances manufactured by them.

W. G. BISSELL, representing Geo. M. Clark & Co. of Chicago, announces his visit to the trade in the East by a postal card, saying: "I will call on you next week in the interest of the Jewel gas stoves. Our line is most complete."

IT WOULD be hard to find a place where more business is done with as little confusion and with greater satisfaction to the trade than at the house of F. M. Borden & Bro. of Philadelphia. Just now all attention is given to the Challenge Iceberg refrigerators, the New Process gasoline stove and the Globe line of gasoline goods which bears their name.

THE CHICAGO & ERIE STOVE COMPANY of Erie, Pa., are enjoying a gratifying business in steel ranges, the demand emanating from various sections of the country. Instead of selling direct to the hotels for which these ranges are specially adapted, the makers are placing them in the hands of dealers, thus giving them the benefit of the retail profits. The company are distributing a circular giving a number of testimonial letters from those who have introduced their steel hotel ranges, the letters showing in a striking manner the satisfaction which these goods have given.

IN STOVE ORNAMENTATION this year urns will supersede the images or figures so prominent last season. Tile work effects will still be in use, but it is expected that there will be considerably less metal ornamentation used than formerly. At least this is the impression derived from a tour among the stove men of Eastern Pennsylvania.

THE GRANDER STOVE COMPANY of Royersford, Pa., will have on the market this season a low-priced square heater. It will be known as the Mars, and will be made in single and double form, with full reversible and direct drafts. It will have an extra large fire pot and a commodious ash pit, a dust damper to check draft, duplex and rotary grate, nickeled feet and skirting, foot rails, tile panels, top ring and swing cover. Surmounted by a handsome urn, it should find many admirers in the trade.

THE BUCKWALTER STOVE COMPANY of Royersford, Pa., will be in the market this season with a new square heater and a new soft coal heating stove. They will also remodel their Eclipse Duplex furnace.

THE BRIDGE & BEACH MFG. COMPANY, St. Louis, Mo., are distributing a four-page circular, in which is set forth the merits of the Superior Air-Tight oak stove, intended for burning coal or wood. The manufacturers state that while the 1891 pattern, with round base, gave general satisfaction to the trade, there was an objection in that an ash pan could not be employed, the ashes having to be taken out at the base with a shovel and placed in the ash pan, causing dust and dirt, in addition to great inconvenience. In the new series of Superior Air-Tight stove, with square base, the company have overcome this objection and have brought out what they consider the finest oak stove ever placed on the market. It is claimed to hold fire from 18 to 24 hours, and is so made that when necessary the outside fire pot can be quickly replaced by simply unscrewing the bolts which connect it with the steel body. The ash pan is large and the grate of the cone-center type for coal and draw-center style for wood. The grate shank for shaking and dumping is inside the fire box, thus avoiding all danger of fire and ashes falling out on the floor. The pipe collars are extra large and a drop smoke door is provided, to obviate any possible complaint of smoking when the stove is connected with a slow flue. The ornamentation of the Superior Air-Tight is neat and effective, and the stove is offered in four sizes, two of which are provided with double sections.

THE FIRESIDE is one of the new things this season announced by the Abram Cox Stove Company of Philadelphia, by means of a circular that is novel in arrangement as well as attractive in style, the outside being printed in deep violet over a design in buff on white paper. Inside it is sufficiently shaded off black to blue to be very rich in effect. The Fireside is an open-fire grate of handsome and attractive appearance, finished in eight styles in nickel, bronze and tile. Comfort and convenience are pleasantly combined with its beauty, as it is so constructed that it can be set to heat an upper room, and when the blower is not in use it sets in front of the ash pit, affecting the eye as pleasantly as when in place. The heater is adapted for hard or soft coal, coke and gas, and in addition to an efficient dust flue it has those provisions for cleanliness so desirable with open fires. The illustrations show it with a large and small square frame and a circular frame, while the description gives full dimensions.

THE J. F. PEASE FURNACE COMPANY, Syracuse, N. Y., inform us that over a year ago they put in their application for over 800 square feet of floor space in the Building of Manufactures and Liberal Arts at the World's Fair. They have been awarded a space amounting to 600 square feet, which they consider very generous treatment by the Commission, in view of the large number of exhibitors who wish to show their products in the section devoted to heating apparatus. Their space is 20 x 30 feet, the latter dimension being frontage on one of the main aisles.

BUCK'S STOVE & RANGE COMPANY, St. Louis, Mo., have just completed an addition to their already extensive works, consisting of a four-story building, which has been erected immediately over their foundry. This building will be used principally for warehouse purposes.

George M. Clark & Co. of Chicago report that they recently took the largest single order ever given directly by a consumer for gas ranges. The order was from Mr. McLennan, owner of the McLennan flats at South Park avenue and Thirty first street, Chicago, and was for 128 gas ranges with water heaters and 97 gas ranges without water heaters, or a total of 225.

Our thanks are due to Frederic W. Gardner, Western manager of the Michigan Stove Company, Chicago, for a very fine black leather pocket book. It contains several divisions for the systematic arrangement of such papers or other articles as are usually carried in receptacles of this character. Stamped on the interior are the company's Garland trade-mark and Mr. Gardner's compliments.

Lyman F. Wilder, Rochester, N. Y., is the patentee of an oil stove of simple and convenient construction, and having adjustable or removable drum, which is employed in connection with a grate supported above the burner.

The Peninsular Stove Company.

Visitors to the Chicago branch of the Peninsular Stove Company, 79 and 81 Wabash avenue, will be pleased to see the transformation recently effected under the supervision of Manager J. B. Copp, ably assisted by the head salesman, Adam Schmitt. The street front has been remodeled, and the entrance is now through double doors at the north. This leaves a broad unbroken front for display windows. A platform, with an ornamental hardwood floor, has been arranged on a level with the windows. On it are shown several of the most artistic stoves made by the company. Back of this platform stands a row of cherry desks for the use of salesmen. The counting house has been removed to the third floor of the building and the space formely appropriated for this purpose has been given over to samples. On one side of the salesroom are two compartments inclosed by ornamental partitions, one of which is a handsomely furnished reception parlor and the other is Manager Copp's private office. The walls of the salesroom as well as the ceiling have been tastefully repspered with a paper of light tint, with a rich frieze of unusual depth extending round the walls. Below the frieze are elegantly framed portraits and pictures, the former being striking likenesses of the officers of the company, while the latter are composed of various subjects selected for their artistic merit. The samples of the company's products shown on the floor present a magnificent array of heating and cooking goods, well worthy of their æsthetic surroundings. Scattered through the room in odd nooks are leather-covered sofas for the entertainment of visitors. The shipping room in the rear has been rearranged for the greater dispatch of business. The shipping clerk's office is in a gallery, which leaves the floor free for handling stoves, which are brought from the upper stories by an elevator and loaded on wagons but a short distance away. The floor of the shipping room is on a level with the floor of a wagon. A larger platform, of a capacity to hold a carload of stoves, runs along the rear of the building in the alley.

The completion of the new arrangements was formally celebrated on the evening of the 7th inst. Invitations were issued to a large circle of business acquaintances by Manager Copp, and they gathered in force to admire the taste displayed. The rooms were illuminated by both arc and incandescent lights, and compliments were freely lavished on the enterprising manager. A collation was served for the further delectation of the guests.

SCRAP.

John Dunlap Company, Pittsburgh, Pa., are distributing samples of Dunlap's double dipped American made roofing plate. This plate, they say, will receive two separate coatings, hand dipping, by the palm-oil process, and each box will contain a guarantee of quality. The firm also make a rolled plate which they describe as a little better in grade than the Lily or Worcester. The sample received is stamped with the words "Dunlap's Double Dipped," and is of IX gauge.

Leyshon & Son have decided to start a tin-plate works in the buildings of Disston & Sons, Front and Laurel streets, Philadelphia, Pa. We understand that they have already two machines erected, one for brights and one for ternes, which they will start up snortly. Their tin house is 120 x 40 feet, well ventilated, and they say their plant is adapted for eight more machines. George Leyshon, Sr., we are informed, will devote his entire time to the work.

James B. Scott & Co., Pittsburgh, Pa., send us circulars in which they say that when the manufacture of Scott's Extra Coated guaranteed roofing plate was begun in this country over a year ago, the Patent Office registered the brand name "Scott's Extra Coated" as a trade-mark, thus protecting the American manufacturer.

The sheet-mill department of the new tin plant recently erected at Niles, Ohio, by the Falcon Iron & Nail Company, was started Tuesday, and the entire industry will be put in full operation in a few days. The buildings are of iron and brick, and the equipments of the latest improved design. The plant will give employment to from 350 to 400 persons and will be a valuable acquisition to the Mahoning Valley.

The Youngstown Tin Plate Company, recently organized at Yougstown, Ohio, and now fitting up the old malleable iron works in that city for the manufacture of tin and terne plate, have made application for a charter of incorporation. It is stated that the machinery for the new plant has been purchased, and the manufacture of tin and terne plates will be commenced in a short time.

James A. Coe & Co., Newark, N. J., are distributing to the trade samples of the Staple terne American roofing plate, which is an article to which we drew attention some time ago. The samples show a well-coated plate that will no doubt commend itself to roofers. In a circular accompanying the samples Messrs. Coe & Co. say that their customers have found their Staple terne to have a uniform gauge and coating and to be easily worked. These plates are furnished 14 x 20 and 20 x 28 IC. The same firm also quote prices on quantity lots of galvanized iron, cold-rolled steel, common black iron, corrugated sheets, &c.

A struggle between the two express companies, the United States and American, to control the New England business, results in a temporary injunction by Judge Barrett restraining the New York and New England Railroad and the United States Express Company from interfering with the privileges of the five-year contract of the American Express Company of December 5, 1892.

Americans are not going to Europe in large numbers this season, judging from the number of empty berths on outgoing steamships. The explanation is supposed to be the rival attractions of the Chicago fair and fear of cholera in Europe and possible difficulty in returning home.

TRADE REPORT.

The Iron Market.

Taken as a whole the Iron and Steel trades are in fairly satisfactory condition. A prominent manufacturer recently remarked: "There is nothing to brag about, and on the other hand, nothing to cry about." The volume of business is large in the aggregate, and indications favor a heavy consumption of material right along, but manufacturers say there is no margin for profit. Notwithstanding this, competition continues keen and prices are as low as ever. As regards the outlook, there are no new features whatever. There is an enormous amount of work under contract and a still larger amount in prospect, the immediate drawback being, that there is more or less scarcity of work actually in hand. The orders are there, but the specifications are not, which is almost as bad as to be without orders altogether. Then the exceedingly fine outlook is in a measure offset by the unsatisfactory financial situation It matters very little to a firm how much work they may have the chance of getting four or six months hence, if in the meanwhile they are harassed for money to get out what they already have in hand, and that is precisely what's the matter with more than one large concern. Under these circumstances, and with due regard to facts, it is not entirely safe to report very confidently in regard to business. As compared with last week, there is probably a slightly firmer tone to prices, and with a more settled and easier money market, things are in good shape for improvement, while trimming down has been done to such an extent that it is hardly likely any one would be found unprepared—even if there were another little flurry.

At Chicago the strike season is now being felt, and more or less disturbance to business is apprehended. Architectural Iron workers went out the past week, workmen at the World's Fair were out for a day or two and the boilermakers and molders are uneasy.

Pig Iron.—Buying in the New York market has been light during the past week, but prices, so far as standard brands are concerned, are steady. We quote Northern brands at $14 50 @ $15.25 for No. 1; $13 75 @ $14.50 for No. 2, tidewater. Southern Iron, same delivery, $14.25 @ $14 50 for No. 1; $13 @ $13.75 for No. 2 and No. 1 Soft.

The "blowing out" of so many furnaces in Virginia and other districts in close proximity to the Philadelphia market, is gradually manifesting itself in a scarcity of good Irons of all grades. Deliveries are called for with much urgency, and unless the conditions change, there will soon be a veritable scarcity. Buying is not particularly active for the reason that there is very little Iron for sale, so that in the meantime all the efforts are to get quick deliveries, hoping that in a week or two, or some time in the near future, orders can be duplicated at the old prices. Those who have Iron for sale are willing to accommodate their customers, but as a rule makers are not quoting, having sold their entire product up to midsummer, and in some cases still further ahead. Second qualities and some of the newer brands are therefore drawn upon to supplement the more favorite brands; and while prices of these are comparatively low and irregular, they are not as heavy a drag on the market as they were a few weeks ago. Taking everything into account, the chances appear to be favorable for continued improvement, by which it should be understood that if there is no falling off in the demand and no increase in production, sellers will soon gain the upper hand in the market. Under present conditions prices are likely to improve; if conditions change the market will change accordingly. Meanwhile the general asking prices are as follows for Philadelphia and equivalent deliveries, with 25¢ @ 50¢ less on Southern brands at Harrisburg and intermediately to Baltimore:

American Scotch, No. 1X	$16 00	@	$16 50
American Scotch, No. 2X	15 00	@	15.50

The prospect of a molders' strike at Chicago, which is now looming up, operates both ways. Some consumers want shipments hurried, while others ask to have deliveries deferred until considerably later in the season. A fair volume of business is being done in local Coke, although the trade is by no means so heavy as it has been. Prices are very steady, but the makers are not looking for an advance, being apparently quite satisfied if they can hold them where they are. Southern Coke is not in general demand, but special trades are being quietly made, some of which run up to very respectable proportions. While our quotations present the prices asked by the most important Southern companies they are cut 25¢ or more by smaller concerns or on desirable orders. Lake Superior Charcoal has not shown any sympathy here with the better movement reported in other markets. Quotations are as follows, cash, f.o.b. Chicago:

Lake Superior Charcoal	$16.50	@	$17.00
Local Coke Foundry, No. 1	13.75	@	14.25
Local Coke Foundry, No. 2	13.00	@	13.25
Local Coke Foundry, No. 3	12.75	@	13.00

There has been no essential change in the Southern markets for Pig Iron during the week. There were no large sales, but a fair run of small orders that were from one to five carloads as a rule, and there were several sales of 500 tons, and in exceptional cases 1000 to 2000 ton lots. The aggregate is of fair proportions for a slow and easy market. Factors here look for an improvement in prices by the middle of summer, and are not disposed to contract for long delivery, but buyers see no inducement to buy much beyond their immediate necessities, as their experience for the last year or two has been that each subsequent purchase has been made at lower than previous prices. There is undoubtedly a liberal melting of Iron for general purposes, and if the consumption is not in excess of current production it is keeping closely up to it. A considerable part of the sales of Southern Iron at Cincinnati is destined for the East, but the jobbing foundries in that district are busy, and apparently using more than the usual quantity of Iron. We hear less of exceptionally low prices, and the market may be called a steady one, the demand running mainly on No. 2 Foundry and No. 2 Soft, and on Gray Forge Iron. Quotations are as follows:

Foundry.

Southern Coke, No. 1	$13 25	@	$13.50
Southern Coke, No. 2	11.75	@	12.00
Southern Coke, No. 3	11 00	@	11.25
Ohio Soft Stone Coal, No. 1	16.00	@	16.25
Ohio Soft Stone Coal, No. 2	15.00	@	15.25
Mahoning and Shenango Valley	14.75	@	15.00
Hanging Rock Charcoal, No. 1	19.00	@	19.25
Hanging Rock Charcoal, No. 2	18.00	@	18.50
Tennessee and Alabama Charcoal, No. 1	15.50	@	15.75
Tennessee and Alabama Charcoal, No. 2	14.50	@	14.75

Metal Market.

Copper.—There has been no change, certainly none for the better, in the condition of the market for this metal. Orders come this way slowly, and are invariably for comparatively small quantities, while inquiries afford no indication of realization of the prophesied lively spring season movement of stock into the channels of consumption. To all accounts the output of the mines, although under restraint, is still excessive, affording sufficient surplus to keep values rather weak. Lake Superior Ingot has been openly offered at 11½¢, regular terms, without stimulating interest on the part of consumers, and offers of futures up to and including December, made on the Metal Exchange, have been quite as futile in attracting speculation. Casting Copper has not fared a great deal better, as far as movement is concerned, and prices are weaker, with anything above 10⅝¢ strictly the exception on ordinary quantities, and 10½¢ apparently a price at which orders for round lots would not be passed. A fair business has been effected in this variety of product, but, like the trade in Lake Superior Cop-

per, the movement is still somewhat behind late calculations. At the close of the week some few small parcels of Lake Superior Ingot were sold at 11⅞¢ for prompt delivery, and on the Metal Exchange there were offers to sell at 11¼¢ for July to September delivery, inclusive.

Pig Tin.—Directly after our review of last week there was a break in prices to 20.45¢ for spot and current month deliveries. Distant futures went to a corresponding point, or say, 20.80¢ for July delivery, and the market presented a rather sickly appearance. The recognized leaders who are supposed to be the heaviest holders, came to the rescue on Saturday, however, taking several hundred tons at from 20.60¢ up to 20 80¢ for May delivery. Following this were smaller purchases for that month at 20.85¢ and for June at as high as 21.05¢, while spot prices were bid up to 20¾¢. This movement, in the face of heavy arrivals and large stock afloat, to say nothing of the unusually liberal spot supply, was rather surprising. It was forcibly illustrated, however, that the bull interest is still in the field and working heroically against seemingly overwhelming odds. Since the first of April, no less than 1830 tons have arrived at this port. Over 1000 tons are due to arrive in a few weeks from London direct, and the chances are that the spot stock at the end of the month will not be far from 5000 tons, the value of which is at least $2.000,000 at present market prices. Additional lots are on the way from the Straits on shipments made during the latter part of the last month, and it is an open secret that the April shipments from the East will be fully up to the average. Upon the whole, it looks as though the leading operators have a heavy burden to carry pending the fate of the McKinley tariff law. At the close of the week prices advanced to 20.80¢ for prompt and current month delivery and 20.85¢ for May, at which figures about 150 tons changed hands. Bids were made on the Exchange of 21¢ for June, 21.10¢ for July, 21.20¢ for August, 21 40¢ for September, and 21½¢ for October delivery.

Pig Lead.—There has been quite a heavy movement and prices have advanced sharply, leaving the market in strong position at the close, with 4.15¢ @ 4.17½¢ apparently inside figures for either spot stock or near future shipments. Transactions involving at least 1800 tons at 4.10¢ @ 4.15¢ can be traced, and there are indications that entirely distinct business, involving a considerable quantity of Lead, has been put through about which no particulars are divulged. Information comes from reliable quarters to the effect that consumption is running ahead of the production at present. It is also stated that some purchases have been made recently by local operators who sold "short" a few weeks ago at prices considerably below those ruling at the present time, on the mistaken idea that the output was largely excessive.

Spelter.—Eastern consumers have purchased very indifferently in this market, and the demand here is slow at the present time. Negotiation has revealed the fact that supplies at primary sources are lighter than has been generally estimated and that consumption is of considerable volume despite the indifferent character of buyers' operations. It is not as easy to buy prime Western at 4 30¢ at the present time as it was a week ago. In fact, that price has been refused during the past few days for several brands, and 4.35¢ is generally asked.

Antimony.—Demand is of routine type, and prices have undergone hardly any change. Spot prices remain at about 10½¢ for Hallett's, 10⅝¢ @ 10¾¢ for L.X. and 10¼¢ @ 10⅝¢ for Cookson's.

Tin Plate.—Arrivals have been heavy, and coupled with slow demand, serve to soften prices for spot goods. Prices are not positively lower, however, holders being encouraged somewhat by advices from the foreign market. In future deliveries business has been slow. From the consumer's point of view, the condition of Tin Plate remains unchanged. A moderate amount of orders is being received for both imported and American Plates at ruling prices.

Coal.

The Anthracite Coal trade continues weak and irregular, as there is only a nominal agreement as to prices; but the companies endeavor to act in unison, at the same time exercising more or less discretion as circumstances seem to warrant. Actual prices for Stove as a basis are about $3.95 ℔ ton, which is a shade under the circulars. Another indication is the price circular of the Finance Company, which makes Free Burning White Ash f.o.b., at New York, Broken and Egg $3.65, Stove and Chestnut $3.90. Both of the small steam sizes, Chestnut and Buckwheat, are scarce and firm. With the exceptions noted, there is no lack of Coal, and while an advance is out of the question, operators affirm that Coal will be no lower. At the same time, the large reserves of the Reading Company are a menace to the market, the supposition being that financial securities may govern sales throughout the year.

Bituminous Coal is considered very cheap, viewed from the basis of the Long Island Railroad and other contracts lately closed on private terms, and respecting which all concerned are discreetly reticent. There is no lack of Coal. Prices in New York harbor $3.10 @ $3 15.

The Philadelphia *Press* says: "The contracts with individual Coal operators are a most expensive luxury for which there is no longer any necessity, inasmuch as the Reading is not now engaged in an effort to control the Anthracite trade. These contracts cost the Reading Company from 20 to 50 cents ℔ ton. The contract with the Finance Company through which it handles the Coal output is also said to be booked for abrogation on the score of economy. Other expensive improvements which came in during the McLeod *regime* are no longer in keeping with the reduced situation financially in which the company finds itself A long epoch of economy and rigor, sackcloth and ashes and plodding is ahead of the company's executive." It is now tacitly understood among the individual Coal operators that their tonnage contracts with the Reading are to be revised and those located along the Lehigh Valley Railroad are to be made out directly in the name of that company.

Production for the week ending April 1 808.000, an increase of 94,000 over the corresponding week last year.

The contract for Pea Coal during 1893, for the Philadelphia Traction Company, has been secured by the Philadelphia & Reading Coal and Iron Company. The contract is for 20,000 to 30,000 tons.

The Lehigh & Wilkes-Barre Coal Company have secured the contract for Pea Coal for the Providence & Stonington Steamship Company. The amount will be in the neighborhood of 40,000 tons.

Coal cutting machines are being successfully introduced in the Monongahela region. A plant of two machines, equal to 200 tons per day, costs $6000.

The Reading Company are making an earnest effort to extinguish the fire long burning on the 3 mile stretch between Newcastle and Glen Carbon, which formerly contained three large colleries.

Application has been made in Nova Scotia for the incorporation of a third large American Coal company.

Financial.

The only cloud hanging over the markets to occasion uneasiness is the renewal of gold exports—$3,500,000 having gone out on Wednesday, and more to follow—coupled with trade and currency conditions that make this movement not only possible but natural. It is well understood that the Austrian Government, operating through the Rothchilds, is providing a metallic basis for its currency, so that in response to the European demand for more gold, America proves to be the most available source of supply, as the yellow metal is not only being displaced here by the continued issue of paper, but diminished exports and augmenting imports make an adverse balance of trade to be adjusted. The foreign commerce of New York for March clearly indicates the general tendency. The imports last month exceeded $63,000,000, exclusive of specie, being nearly $10,000,000 over the same month last year, and larger than for any previous March in the history of the port. The principal items were coffee, sugar and rubber, all free goods. For the first three-quarters of the current fiscal year the merchandise imports are $57,-000,000 over any former year. On the other hand, shipments were comparatively meager, and for three months the total, exclusive of specie, was $23,000,000 below the corresponding total for last year. The recent advance in the price of wheat prevents a free outward movement of grain, but a favorable point is the reviving foreign demand for cotton, and moreover foreigners are again inclined to invest in American securities. As a fur-

ther check to the drain of gold, a round amount of bonds issued by various corporations may be placed in Europe. Then, too, while Americans will this summer disburse much less money abroad, the expenditures of foreigners here will be largely increased. Prospects are supposed to be much better now that no labor troubles will arise to mar the Columbian Fair. One ground for this assurance is found in the decisions by the United States Courts at Toledo, and New Orleans, which hold it a violation of the Interstate Commerce Act for railroad employees to combine and refuse to handle the traffic of connecting lines, and that a combination which stops the wheels of trade and commerce is illegal. Another assuring circumstance bearing upon our credit abroad and upon confidence in the general situation, arises from the fact that the Administration has no expectation of issuing bonds for the procurement of gold before the meeting of Congress, though it is conceded that the Treasury is liable meanwhile to be considerably depleted.

The Government report on the condition of winter wheat strengthened the upward tendency of prices previously observed, so that the net advance was something like 3¢ ℔ bushel. Spring seeding in Illinois is somewhat ahead of last year. South of the Ohio River prospects were never better. In Oregon and Washington the acreage will be increased. Cotton fluctuated under speculative influences. Altogether prices in the merchandise market average better than a year ago, and it does not appear that uneasiness in financial circles has had much effect outside, nor has tariff agitation.

Chicago Report.

Scrap.—Country dealers have latterly rushed in their stocks too rapidly and the supply is now in excess of the demand. Cast Scrap especially has become a drug and is lower in price, which will soon affect the buying price. Dealers' buying prices are as follows:

	Per net ton.	Per ℔
No. 1 Wrought Scrap	$13.00	....
Machinery Cast	10.00	....
Malleable Cast	7.00	....
Stove Plate (free of burnt)	7.00	....
Burnt Iron and Grate Bars	5.00	....
Sheet Iron and Hoops	4.00	....
Plow Steel and Breaking Stock	8.50	....
No. 2, such as Shovels, Hoes, &c.	4.50	....
Old Boilers—whole (Iron)	8.00	....
" (Iron)—cut in single Sheets and Rings	12.00	....
Old Gas-Pipe and Boiler Tubes	9.00	..
Cast Borings	5.00	....
Turnings	6.00	....
Horseshoes	12.50	....
Copper Bottoms	....	8¢
Copper Clips and Heavy	....	9½¢
Heavy Brass	....	8½¢
Light Brass	....	4 ¢
Pipe Lead	....	3 ¢
Tea Lead	....	2¾¢
Zinc	....	3 ¢
Rubber	....	3 ¢

Anthracite.—Local dealers do not anticipate any change in prices until toward the close of this month. Carload lots of 12 net tons are quoted as follows:

	Egg, Sto. Grate.	and Ch.
Chicago, Ill	$5.85	$6.10
Milwaukee, Wis	5.85	6.10
Kansas City, Mo	9.05	9.30
Council Bluffs, Iowa	9.05	9.30
St. Joseph, Mo	9.05	9.30
Leavenworth, Kan	9.05	9.30
Omaha, Neb	9.05	9.30
Burlington, Iowa	7.35	7.60
Des Moines, Iowa	8.80	9.05
Davenport, Iowa	7.15	7.40
Dubnque, Iowa	7.15	7.40
Madison, Wis	7.35	7.60
St. Paul, Minn	8.35	8.60
Lincoln, Neb	9.20	9.45
Sioux City, Iowa	9.05	9.30
Aberdeen, S. Dak	9.10	9.35

Colorado Anthracite.

COLORADO FUEL & IRON COMPANY.

Denver	$8.00
Pueblo	8.00
Colorado Springs	8.00
Leadville	8.00
Cheyenne, Wyo	10.00
All points between Denver and Missouri River	9.35

CONDITION OF THE

Hardware Trade.

TRADE continues in very gratifying volume, and there is a general activity throughout the country, manufacturers, jobbers and retailers doing a very satisfactory business. While there is an excellent demand for nearly all kinds of Hardware, there is a special activity in seasonable goods. Builders' Hardware is moving in large quantities, with a good demand also for Heavy Hardware. In several lines there is difficulty in obtaining goods as fast as called for, and the market in some branches shows an improvement in tone, with slight advances in quotations. There is still some complaint in regard to collections. The outlook for future business is regarded as very gratifying.

Advices from Chicago.—Jobbers have advanced Wire Cloth to $1.50, as was foreshadowed last week; it is now very scarce, as, despite the increased output by the factories, the demand has exceeded all anticipation and stocks here have been run off rapidly. The general demand for Hardware has greatly improved since our last report and jobbers are now very busy. Roofing Plates are in good demand. Heavy Hardware has improved as well as Shelf, and orders are large in every department.

Notes on Prices.

Cut Nails.—Large quantities of Nails are moving, and in the matter of volume the market is in a very satisfactory condition. Prices are substantially as at our last report, the general quotation being $1.20 for carload lots at mill, a figure which is, however, shaded in some cases under pressure. The new card is referred to almost uniformly as working satisfactorily and the understanding in regard to averages is well carried out. New York quotations are $1.40 for carload lots on dock and $1.60 from store.

Advices from Chicago.—In Steel Cut Nails the situation is not satisfactory to manufacturers. Low offers are being made here by outside concerns that are again using Chicago as a dumping ground for accumulated stocks. The prices made to move such stocks are emergency prices and are not recognized in the trade as regular rates, which are continued at $1.35 for usual deliveries, on customary terms. Jobbers quote $1.50 for small lots from stock.

Wire Nails.—The Wire Nail market is in excellent condition with a large demand and firm tone. The advance in the card rate to $1.55 f.o.b. at mill, with Cleveland as the point of equalization for the West and Pittsburgh for the East, is well maintained, with some possibility of a further advance in the near future. Small lots from store in New York are quoted at $1.80 to $1.85.

Advices from Chicago.—Wire Nails are selling more freely from jobbers' stocks than from factory. Manufacturers are now busy shipping to jobbers on old orders, and the last advance may also have checked new business for the time being. The factory price is firm at $1.67 Chicago, while small lots from stock are held at $1.75, and carloads $1.70.

Barb Wire.—There is a heavy demand for Barb Wire and shipments are with difficulty made by manufacturers as promptly as desired by their customers. The market in the matter of price has an excellent tone and the quotation of $2.45 to $2.50 for Four Point Galvanized in carload lots at mill is well maintained. In New York the price is $2.65 to $2.70 for carload lots on dock.

Advices from Chicago.—A heavy trade is now in progress, and the hight of the season has not yet been reached. Local manufacturers are making unusually prompt shipments under the circumstances, having had very heavy stocks in their warehouses when trade opened, which enabled them to keep up with the demands on them. Should trade continue to increase, they will also fall behind with their colleagues in other sections. Prices are firm but unchanged at $2.20 for Painted and $2.60 for Galvanized from factory and 10 cents per 100 advance from store.

Holland's Hose Reel.—This Reel is manufactured by the Hollands Mfg. Company, Erie, Pa. It is sold at $4 f.o.b. Erie, subject to a discount of 30 per cent.

Bright Wire Goods.—The market continues in substantially the same condition as noted last week, but there are indications of a reaction from some of the low prices quoted by some of the manufacturers, a few of the extreme prices having been withdrawn.

Bolts.—The condition of the Bolt market on the whole is more satisfactory than for some time past. The manufacturers, as a rule, are very full of orders, and in several lines are unable to turn out goods as promptly as desired by their customers, some of whom experience considerable difficulty in getting enough to meet their requirements. Prices in some lines, such as Common Carriage Bolts and Machine Bolts, are firmer although not quotably higher. Notwithstanding the fact that the market is an open one, it is regarded as in better condition than for a long time.

Blocks.—The Block market continues demoralized. Manufacturers are apparently vieing with one another to see who can name the lowest prices, notwithstanding the fact, which is generally conceded, that at current quotations Blocks are selling below cost.

Rope.—In sympathy with the condition of the Hemp market prices for Manila and Sisal Rope are slightly lower, notwithstanding the fact that no formal announcement has been made by the manufacturers. The market for round lots is represented by the following base prices, f.o.b., New York, which are subject only to a discount of 1½ per cent. for cash:

	Per pound. Cents.
Manila	8¾ to 9
Sisal	7¼ to 7½
New Zealand	6¾ to 7

Wrought Iron Pipe.—There is a heavy demand for Wrought Iron Pipe and most of the mills are occupied on orders. Prices do not show material change, but are perhaps a shade firmer than a week or two ago. Some of the manufacturers, however, are making quotations slightly lower than have previously ruled and the market is thus characterized by some unevenness. On the whole there is apparently a better tone, the downward tendency having been in a good measure checked.

Queen Washing Machine.—Buckeye Churn Company, Sidney, Ohio, are manufacturing this article. The machine is sold to the trade at $30 per dozen, 60 days, 2 per cent. off for cash in 10 days.

Leather-Capped Chisel Handles.—These Handles are put on the market by F. C. Copeland, Worcester, Mass. They are sold from the following list, which is subject to a discount of 25 per cent.:

Tang Firmer Leather-Capped Handles.

Polished and Heavy Cast Brass Ferrules.

No.	Per gross.
0 ⅜ to 1¼ inches, assorted, one dozen in a box	$11.33
1 ½ to 2 inches, assorted, one dozen in a box	12.00
2 ½ to 2 inches, (medium) one dozen in a box	12.32
3 1 to 2½ inches, (large) one dozen in a box	12.64

Socket Firmer Leather-Capped Handles.

No.	Per gross.
4 four sizes, one dozen in a box	$10.00
5 three " " " " "	10.00
6 two " (large) one dozen in a box	10.33

Socket Framing Leather-Capped Handles.

No.	Per gross.
7 three sizes, one dozen in a box	$10.00
8 three " (large) one dozen in a box	10.33

Housewives' Delight Can Opener.—This Can Opener is manufactured by F. E. Kohler & Co., Canton, Ohio, and sold to the trade at $10.80 per gross.

Weed Destroyer.—This article is put on the market by Shaw & Clancy, Racine, Wis. It is sold to the trade at $12 per dozen, with 5 per cent. off for cash in ten days.

Buckeye Churn.—This Churn is manufactured by the Buckeye Churn Company, Sidney, Ohio, and is sold from the following list, terms 50 per cent. off 60 days, 2 per cent. for cash in ten days.

No.	9	churns	1 to 4	gallons		$6.00
"	10	"	2 " 6	"		7.00
"	11	"	2 " 8	"		8.00
"	12	"	4 " 12	"		9.00
"	14	"	8 " 15	"		14.00
"	16	"	10 " 20	"		16.00
"	18	"	15 " 20	"		20.00

Terne Plates.—John Dunlap Company, Pittsburgh, Pa., are manufacturing Terne Plates, under the brand of Dunlap's Double Dipped, in each box of which is a printed guarantee, which they state insures the purchaser that every box will be up to standard. These plates are quoted, f.o.b. Pittsburgh, as follows:

Dunlap's Double Dipped.

I.C. 14 x 20	$ 8.25
IC. 20 x 28	16.50
IX. 14 x 20	9.50
IX. 20 x 28	19.00

They also make a rolled plate, which is sold at the following prices, f.o.b. Pittsburgh:

Dunlap's Domestic.

IC. 20 x 28	$12.00
IX. 20 x 28	15.00

Glass.—The condition of the Glass market is unchanged, as trade continues quiet, with no change in prices. While some local jobbers see a slight improvement in orders received, it is generally acknowledged that so far this month business has not been so large in volume as it was for the corresponding time in March. The subject of greatest interest in Glass circles during the past week has been the visitation of the Eastern cities by the National Window Glass Committee. The committee visited Eastern manufacturers, importers and jobbers, to endeavor to secure their co-operation, and if possible to bring them into the association. The committee visited Philadelphia, Baltimore, New York and Boston. While, perhaps, nothing definite was accomplished during the trip, the result of the various conferences is spoken of as having been satisfactory. It is understood that the committee received assurances that the New Jersey manufacturers would join the association and that the New York jobbers would also become members. The associations of the New York and Boston importers have been trying for some time to agree upon prices applicable to both cities, but have been unable to do so, although the members of each association have come to a satisfactory understanding among themselves. Under these circumstances it is not unexpected that the New York and Boston importers are yet undecided whether they will co operate with the National Association. The National Plate Glass Company, with a capital of $8,000,000, is the latest addition to Glass associations. This company was incorporated at Springfield, Ill., having, it is understood, a plan of forfeitures, &c., similar to that of the Window-Glass men, but whether jobbers will be admitted to membership has not been announced. This company is supposed to include in its membership all the Plate Glass factories in the United States, who are now distributing their product through a general agent at Pittsburgh Prices are as follows: American Window Glass, 2000 boxes at one time, 80 and 10 and 10 per cent. discount; carloads, 400 boxes, 80 and 15 per cent. discount; less quantities than carloads, 80 and 10 per cent. discount. Freight allowed on car lots and over, not to exceed 17½ cents per 100 pounds; less than car lots, f.o.b. at shipping point. French Window Glass, 75 and 10 and 5 per cent. discount. American Plate ranges in price from 50 and 10 and 7½ per cent. discount to 60 and 5 per cent. discount. Imported Plate Glass, 60 per cent. discount to 60 and 10 and 5 per cent. discount.

Old Rubber.—The following are the current prices paid for Old Rubber delivered in New York:

Car Springs, in ton lots, ℔ lb.	....	@	$0.03½
Rubber Shoes, in ton lots ℔ lb.	....	@	.03
Large Hose, ℔ ton	....	@	9.00
Wringer Rolls, ℔ lb	....	@	.04½
Wringer Wire Rolls, ℔ lb	.01	@	.02
Syringes, ℔ lb	....	@	.05

Old Metals.—The following are the current prices paid for Old Metals in New York:

Heavy Copper	℔ lb	9½¢
Light and Tinned Copper	℔ lb	8½¢
Heavy Brass	℔ lb	7¢
Light Brass	℔ lb	6¢
Lead	℔ lb	3½¢
Tea Lead	℔ lb	3½¢
Zinc	℔ lb	2½¢
No. 1 Pewter	℔ lb	14¢
No. 2 Pewter	℔ lb	7¢
Wrought Scrap Iron	℔ gross ton,	$13.00
Heavy Cast Scrap	℔ gross ton,	9.00
Stove Plate Scrap	℔ gross ton,	6.00
Burnt Iron	℔ gross ton,	4.00

Old Rags, Paper, Etc.—The following are the current prices paid for Old Rags, Paper, &c., delivered in New York:

No. 1 White Rags	℔ lb	4 ¢
No. 2 White Rags	℔ lb	3 ¢
Mixed Rags	℔ lb	1½ @ 1¾¢
Blues and 3ds	℔ lb	1¾ @ 2 ¢
Hard Sized White Shavings	℔ lb	2¾ @ 3 ¢
No. 1 White Book Shavings	℔ lb	2¼ @ 2⅝¢
No. 2 White Book Shavings	℔ lb	1½ @ 1¾¢
Light Book Shavings	℔ lb	⅞ @ 1 ¢

No. 1 Jute Bagging	℔ lb	1¼¢
Mixed Bagging	℔ lb	1¼ @ 1⅜¢
No. 2 Bagging	℔ lb	1 ¢
Hemp Twine	℔ lb	⅞¢
Manila Rope	℔ lb	2½¢
Jute Rope	℔ lb	2¼¢
Mixed Rope	℔ lb	1¾ @ 2 ¢
	℔ lb	¾ @ ⅞¢

Trade Notes.

The American Consolidated Mica Company of Minneapolis, Minn., have recently been incorporated with a capital of $600,000. The incorporators are James H. Bishop, Thomas E. Bishop, Emery F. Dodson and Charles F. Brown of Minneapolis, and Joseph B. Dickover of Hot Springs, N. Dak.

L. D. Berger, 224 Arch street, Philadelphia, Pa., issues a neat little illustrated catalogue and price-list descriptive of the extensive line of goods which he manufactures and handles. These include Tinners' Hardware, Plumbers' and Roofers' Supplies and other articles. The pamphlet of 60 odd pages begins with Tinners' Trimmings, Stove Pipe Elbows, Dampers, Knobs, Stove Bolts, &c. Attention is then given to Conductor Fasteners, Hooks, including Gas Pipe Hooks, Eave Trough Hangers, Conductor Pipe and various other articles. Later on attention is directed to Tiles, Crestings, Finials, &c. Toward the close of the publication notice is made of Speaking Tubes, Registers, Coal Hods and Tinners' Tools. An alphabetical index at the close facilitates reference.

William Vogel & Bros., 37-47 South Ninth street, Brooklyn, refer to business as excellent, having done more in amount last month than for any corresponding time since their establishment in 1863. They produce largely of Oilers, Sheet

Metal Screws, Seamless Boxes, Paint Cans, Oil Stoves and a large variety of specialties, frequently receiving orders for goods that require much special machinery and the employment of a large force, sometimes covering a year's time to execute. They build their own special machinery, own their nickel plating plant and lithographing outfit for the decoration of tinware, &c., all of which is operated on the premises. A new brick building 60 x 100 feet, connecting with their existing factory, has recently been completed, which faces on Kent avenue. It has all the latest improvements, including automatic sprinklers, and is six stories high. Quite recently they have assumed the manufacture of many patented specialties brought out by H. Clayton & Co., and for which they are selling agents.

THE WESTERN ZINC COMPANY, with a capital stock of $500,000, have recently been organized at Joplin, Mo. Among those interested in the enterprise may be mentioned Wendell Goodwin, George H. Wirth and A. E. Walradt of New York; George H. Andrew and Ed. Cunningham of St. Louis and Arthur E. Spencer of Joplin.

THE ALUMINUM ALLOY METAL COMPANY, Hampton, Iowa, inform us that the prospects of business for the coming season are exceedingly flattering, and trade is likely to be very much in excess of last year. The general agents for the company are the La Rue Hardware Company, Kansas City, Mo., and the Prusia Hardware Company, Fort Dodge, Iowa.

READERS will be interested in a line of dairy supplies illustrated and noted in the prominent announcement elsewhere of the Geuder & Paeschke Mfg. Company, Milwaukee, Wis. A very large assortment of goods in this line is made by the company referred to, and those wishing to inform themselves on the subject will do well to write for the full catalogue published by the firm.

AT 9 West Fourteenth street, the New York office of W. E. Beveridge of Baltimore, E. D. Luxton, the manager, announces that the quality of the Beveridge Automatic Cooker has been improved by the use of a superior tin plate and high-grade workmanship. Arrangements have been completed by which orders can be filled promptly, notwithstanding the annoyance of a fire at the factory in Baltimore a short time ago.

AN ADVERTISING POSTAL CARD, issued by the Broad Gauge Iron Stall Works, 53 Elm street, Boston, Mass., directs attention to Worthley's Slow Feed Manger, the Popular Wrought-Steel Rack and other stable fittings, besides giving price-lists.

THE STARK MACHINE & TOOL COMPANY, Buffalo, N. Y., report great activity in their manufacturing department, having booked during the past week orders for two heavy 10-foot Power Shears, 15 No. 1 Stark's Process Retorts, two No. 340 Power Presses, and four outfits of Tinners' Machines.

THE AMERICAN STAMPING COMPANY inform the trade that the opening of an office, sample room and warehouse at 104 John street, New York, has been followed by excellent results, as it enables their patrons in the city, as well as those visiting New York, to select their goods by sample, instead of relying entirely upon catalogues. They issue a general invitation to the trade to call and inspect their goods.

PRICE-LIST No. 3, issued by the Parr Register & Mfg. Company, Buffalo, N. Y., illustrates and describes a full line of Hot-Air Registers and Ventilators which they manufacture. In presenting this catalogue to the trade they call attention to the particular care that they give to fitting so as to make a smooth working register. They also mention other points of advantage. The articles described include Vertical Wheel Registers, hot air Registers and Ventilators, Hot-Air Registers and Border Frames, Register Faces, Convex Registers, Circular Top Registers, &c. Numerous illustrations are presented and full tables of sizes and prices are given.

RIEHLE BROTHERS TESTING MACHINE COMPANY of Philadelphia, Pa., are meeting with an active demand for their machines, and among recent orders may be named the following: A 30,000 pound vertical screw-power testing machine for the American Telephone & Telegraph Company, New York City; a U. S. Standard 1000-pound cement testing machine for the Syracuse Water Board, Syracuse, N. Y.; a 20,000-pound vertical screw power testing machine with indicator for the Leland Stanford, Jr., University, Palo Alto, Cal.; a 60,000 pound machine for the Maine State College, Orono, Maine; a 20,000-pound horizontal screw power testing machine for the Ewart Mfg. Company, Indianapolis, Ind.; a marble basin hole cutter for L. Hilgartner & Son, Baltimore, Md.; a 5000 pound transverse testing machine with indicator for testing specimens 48 inches long for the Gillett-Hertzog Mfg. Company, Minneapolis, Minn., as well as many others.

THE NEW PLANT of the Ellwood Steel Company, at Ellwood City, Pa., manufacturers of sheet steel, has been put in operation, and is expected to be running in all departments about the 15th inst. The product of the new concern will consist of sheets, light sheet and fire bed, either pickled or cold rolled, or both. The officers of the Ellwood Steel Company are: David A. Dangler, president; H. H. Simpers, secretary and manager, and John Sherwin, treasurer.

W. W. PRYOR & CO. have recently commenced business at 81 Chambers street, New York, as manufacturers' agents and jobbers in Hardware and House Furnishing Goods and specialties. W. W. Pryor has for some years been connected with the Metropolitan Hardware Company, of which his father, R. W. Pryor, was the head, their business being at 32 Vesey and 26 Barclay streets. For a portion of his time with that house he served them as buyer. One of the features of the new concern will be to secure buying agencies for Hardware houses out of town who may be desirious of having a resident agent here. Another will be to purchase goods from manufacturers who are overstocked and wish to unload goods for cash, without disturbing the channels of their regular trade.

JOHN P. LOVELL ARMS COMPANY, Boston, Mass., are putting on the market Small's Fire Escape, which is described as being self-regulating and reversible acting. It is made of rolled pressed steel, nickel plated, and weighs, without the rope, 7 ounces, and is warranted to hold 1000 pounds. One or two persons may use it at a time. The device consists of a hook to be firmly screwed into the woodwork inside the room. To this is attached best quality rope of sufficient length to reach the ground. The rope is run through a V-shaped piece of metal to which is molded a ring through which a strong band is passed. This band is placed over the head and under the arms and forms a perfect sling in which a person may descend and at the same time have both hands free to grasp the V-shaped pulley and regulate with ease and surety the speed of his descent.

DIETHER & BARROWS, Fort Wayne, Ind., have engaged C. M. Avery, who is widely known to the trade, as their direct representative. They advise us that at the present time they are in receipt of liberally increased orders for their Weisell Washing Machine, and that usual orders for their line of standard patterns are given prompt attention. They are now building extensions to their new factory, which they state will enable them to insure prompt deliveries.

AMONG the shipments of the Parr Register & Mfg. Company, 96 to 100 Georgia street, Buffalo, N. Y., during March were two carloads of Registers to St. Louis, one carload to Kansas City and two carloads to Chicago.

THE LUDLOW-SAYLOR WIRE COMPANY, St. Louis, Mo., report a brisk trade in their Art Metal Department. They are now finishing an elevator inclosure for a local clothing concern. This inclosure is oxidized copper plated, of attractive design, and will be a work of art when completed. They also furnished to the same concern a quantity of nickel plated show window fixtures. They are also at work on an elevator inclosure of ornamental iron for the new High School building, St. Louis.

Composition of Smoke.

From an English exchange we extract the following:

In a paper before the Russian Technical Society, by P. Laktine, on "The Composition of Smoke," the author observes that all the efforts made to suppress smoke have been unsuccessful because its elements have not been sufficiently studied, the gaseous portion having always been analyzed, while the solid and liquid constituents have remained but little known. It is, however, to the latter that smoke owes its injurious qualities, which are especially manifest in large towns. When substances, such as coal, peat, lignite and wood, containing a large proportion of hydrogen, are burnt, light products of decomposition, especially those containing hydrogen and carbon, are disengaged under the influence of heat; and their disengagement is complete or partial, so that the solid carbides, which contain less hydrogen and carbon, and which are present in a state of incomplete combustion, are drawn along by the light products. It is in this case that carbonic acid, nitrogen and the remainder of the oxygen unite, not only with carbonic oxide, but also with the substances not burnt, consisting of carbon, hydrogen, oxygen and a little nitrogen, while pure carbon is disengaged in the state of fine powder. All the above substances form a mass of light gray, yellowish gray or dark gray color, called smoke. The greater disengagement of smoke when a fresh quantity of fuel is thrown on a fire grate is explained by the difficulty which air has in reaching the furnace across the coal, thus causing a cooling down. The following are the conclusions arrived at by the author: 1. The formation of smoke is inevitable, even with the most perfect stoking, if the fuel contains ash and water. 2 Suppression of smoke by means of complete combusion is impossible. 3. A small portion of the fuel is always lost through becoming volatilized with the smoke or combining with the ash. 4. The ordinary methods of analyzing ash by direct calcination are incorrect, and should be superseded by others.

The London General Omnibus Company have recently fitted electric lamps to 140 of their omnibuses. The battery is placed under one of the seats and a lamp of special design is suspended in the center of the roof, giving a most satisfactory light. The installation is said to have been very successful. The ticket inspectors of the company also use an electric light, consisting of a pocket accumulator and a button hole lamp. This system has been in use for a year and is said to give complete satisfaction.

Where Patience Is Expensive.

Patience is not always a virtue. When a water back has accumulated so much sediment that no ordinary fire will heat the water and the patient servant or house-wife is too careful of complaining, thinking there is no remedy for it but to pile in the coal and burn double the quantity needed for cooking, then it would be better to complain. The roof has a small leak, so small that only a little spot is seen in the ceiling of some chamber room where it cannot do very much damage and no complaint is made because it is so disagreeable to tell abont things that require an expenditure of money. After a while a driving storm comes on, lasting several days, and the little leak has let water down on a frescoed ceiling, and then the complaint comes too late. It is the same with business men. They don't like to complain, but feel conscious that things are not going right. It may be the clerks in the store are not as attentive as they should be to the interests of their employer, but he is kind hearted and does not want to complain; his patience is far from a virtue. The men in the tin shop have got into a way of running things their own style and have come to think that the workman knows it all and cannot be told anything by one who never served an apprenticeship to the trade, and make it tiresome for the boss to remonstrate; and if he gives in to little delinquencies he may be sure that big ones will follow and his patience will be expensive. This might be carried to large interests where the volume of trade was unsatisfactory and for which a remedy might be found, but through a disposition to be patient the opportunity for relief is not embraced and patience has worked irreparable injury.

Pay Attention to Details.

"Genius" has been defined by a great, though somewhat cynical modern philosopher as "an infinite capacity for taking pains." We may similarly define the culty which makes a man a master of his craft, as an infinite capacity for mastering and assimilating small details, many of them apparently trifling and insignificant, but all going in the aggregate toward making the solid foundation of knowledge and experience necessary to the attainment and retention of success in almost any line of business. This, with indomitable persistence and a spirit which defies discouragement, is the passkey which has, as a rule, unlocked the doors of fame, wealth or influence to those men who, not having inherited any of these things, have risen out of the crowded ranks of labor and stand to-day among the leading engineers, manufacturers and captains of industry in the United States, men, many of them without advantages of education, or even of a trade training to push them upwards. Self-helped and self-improved they have gone along patiently, picking up practical knowledge at the bench or forge, or in the mill, paying attention to every trifling detail of their craft or business, and storing up the knowledge gained until they find themselves in possession of a fund upon which they can draw at will, and which stands them in good stead in any eventuality. They have, as it were, saturated themselves with the details of their craft, keeping a single eye on the mastery of it.

A Solid Foundation.

Such are the men who are bound to rise. And, fortunately for the youth of this country, similar success is open to each and all provided they possess the necessary ability to secure advancement, and the solid qualities which hold success when grasped. But among these qualities stands prominent that faculty for mastering and absorbing trifling details of which we have spoken. No shallow knowledge will ever make and keep a man foremost in his trade or profession. There must be a thorough, conglomerate-rock foundation of details upon which alone his knowledge and experience may be built and stand. Big blocks of knowledge are very necessary to the building, but it is the every day experience in little scraps which serves to bind them together and so make a stable edifice. We do not think this fact can be too strongly impressed upon the minds of the younger men and boys who have the ambition to rise out of the rank and file. Now is the time for them to gather in the materials on the lines we have sketched out, and there need be no limit to their ambition or to their attainments.

Can Tin Plate Be Too Good.

The charge is now made that American tin plate is too good. But a short time since the objectors to the American tin-plate industry asserted that tin plate could not be made here, that there was something peculiar about it which had enabled the Welsh to monopolize the trade, and that they would always retain control of it. When a few works were started on this side of the Atlantic their product was very critically inspected and the tin plate pronounced fairly good, but much inferier to imported tin plate. Roofing plates first began to earn some commendation for themselves, but the question was then asked, How about bright plates? For a time it really looked as though bright plates were too hard for any but a very few firms to attempt to make. Now, however, American bright plates are becoming quite well known in the trade, and the profonnd criticism is heard that they are too good. It is stated by experts who represent foreign manufacturers that the American bright plates turned out by our best-known makers are too carefully made, being especially too thickly coated with tin. The change thus wrought in the tone of the criticisms is too marked to be allowed to pass without comment. The American tin-plate industry has won the first great point of advantage in the fight for American markets.

Light Welsh Plates.

It is curious that this point has been overlooked by our foreign competitors. They seemed to take the matter for granted that cheapness was the sole end and aim. They believed that the price per box governed everything. They evidently had the impression that American consumers would buy the merest semblance to tin plate if it were offered at an extremely low price. Setting to work to achieve this result, they rolled their sheets thinner to make their boxes weigh less; accomplishing a double purpose in this respect, as they then paid less duty at our ports of entrance. With marvelous skill in shaving items of cost they succeeded in reducing the cost of tin on bright plates even when it was thought by able and most expert tin-plate makers that the limit in this respect had been reached years since. Confident that raw American practice could not approach such scientific skimping, they, metaphorically speaking, rubbed their hands and cried. "Aha," pointed to their 90-pound boxes with a trace of tin on the steel and defied all America to produce their equal. It will be some time before Americans who have any regard for their reputations will attempt such a feat. This was evidently the brilliant method for holding trade which some of the British journals had in view after the McKinley bill was passed, when they declared that the increased duties would be nullified by the further cheapening of the cost of producing tin plates.

American Bright Plates.

There is no country in the world in which a consumer is so willing to pay a fair price for a good article as in the United States. Buyers are shrewd, and if possible they would be glad to get more than the worth of their money. But cases are very rare indeed in which a manufacturer deliberately purchases inferior material. Consumers of tin plate have for years been finding increasing

fault with the tin plate shipped them from abroad, and have vainly asked for a reform in makers' methods, threatening to engage in the business themselves if this were not done. Better and not worse tin plate has been the demand of the American trade generally. It is now to be had, and in increasing quantity every month, and those who say that American tin plate is too good do not understand the temper of the people. We have been informed by a very large manufacturer of tinware that the goods which he is now making up from American stock will last ten times as long as those made from imported plate of what professes to be the same character. His testimony is without prejudice, as he is not interested in the manufacture of tin plate, but buys in the open market to the best advantage. The comparison so strongly made in favor of American tin plate may be an over-statement; but that is the best evidence of the high standing in the trade which American bright plates have won for themselves.

Heating Vehicles.

There are those living who can well remember when many country churches were either not heated at all in winter, or so imperfectly warmed that they might nearly as well have been left entirely cold. The foot-stove, as it was then called, exists no longer, except perhaps as a relic of a past order of things. Not one in 10,000 of the younger generation has ever seen this contrivance. It usually consisted of a sheet brass or tin case, perforated in fancy patterns and having a receptacle for live coals of wood in the interior. Air entered to support combustion, and gases of combustion found egress through the holes in the case. This foot-stove was placed under the feet to keep them warm in church, while the good minister, as was his wont in those days, devoted much of his eloquence to what under the circumstances was almost an alluring description of unquenchable fire. People were then also in the habit of using these foot-stoves to keep the feet warm in vehicles in cold weather. Heated blocks of wood wrapped in a woolen blanket, hot bricks or jugs of hot water, corked and wrapped in the same manner, were common makeshifts, used as substitutes for the foot-stove. Since the advent of railroads attention has been given to the warming of large vehicles; cars on steam railways and later cars drawn by horses on street railways have been rendered quite comfortable by artificial heating. There is still room for improvement in methods. Within a very few years the substitution of steam and hot water heating appliances for stoves in cars has been made the subject of numerous patents, and some of these have gone into extensive use. There seems no reason why smaller vehicles cannot be practically warmed, and at the same time ventilated without the discomfort of opening windows in cold windy weather.

A Brougham Heated by Warmed Air.

At least this idea has been thought feasible in Germany. A patent for an apparatus for heating vehicles has been issued in that country and a recent trial of the invention in Berlin is said to have given satisfactory results. The application was made to that kind of a carriage known as a brougham, the body of which is quite low, so that it is easy to step into it from the ground. The fuel used by the German patentee is petroleum oil, carried in a small cistern on the roof of the carriage, and a sort of lamp placed under the seat between the hind wheels is fed by a tube from the reservoir. The descriptions of the apparatus yet seen do not set forth the manner in which air, after being heated, is introduced into the carriage without also carrying in the smoke of the burner; and, altogether, the contrivance does not seem to be an arrangement that a Yankee would be particularly proud of. Notwithstanding its crude character, it contains a hint of a want in this country and in all cold climates; and it points to the most convenient fuel for supplying the want. Country physicians often suffer much from cold during their long rides in winter, and a cheap practical method of heating covered vehicles would be appreciated by many other people as well.

"Wanted! Good All Around Men."

BY J. O. T.

Assuming that there is an increasing demand for skilled workmen which is in excess of the supply, with the further claim—which some may dispute—that the standard of excellence rules lower now than formerly, or rather that the average mechanic of to-day is content with a limited knowledge of his trade, it may be well for all interested to consider the matter, seeking the causes and, perhaps, suggesting remedies which may alleviate if not cure, the confessed evil We may say without fear of contradiction that no man can become a reader without first learning the alphabet, nor can he hope to become familiar with the polysylables of a trade without a mastery of the A B C thereof. From this acknowledged necessary foundation the education of head and hand may be carried to prominence or suffered to remain on a low plane, and it almost seems as if a majority of workmen were content to deserve the opprobrious name of "mudsills," if their apparent willingness to stay down be taken in evidence. Perhaps, it should rather be said that there is not a general desire to thoroughly learn the trades whereby we expect to gain a livelihood because of the necessity or inclination to make said trades profitable before time is spent to mature them, which is like gathering fruit blossoms for their beauty and fragrance and getting a present minor satisfaction at the expense of future loss.

Here we may possibly find why the graduates of trade schools are, as a rule, likely to become better workmen than those who are obliged to gain their technical knowledge in the old way. The word "obliged" is used deliberately for there is little doubt that intending mechanics would prefer a trade school to a workshop if they could afford it. In the one case they pay a present price for learning a trade, and in the other they learn a trade for present pay. Let us take two boys of equal capacity, and put ting one in a modern mechanical school and the other in an average shop; see how they are likely to turn out. We will call them for our present purpose the student and the apprentice.

Student—if we are not misinformed—does not labor for immediate pecuniary profit either to himself or others, but is sowing seed for a future harvest. It would be poor economy for a farmer to eat his seed corn, but we may conceive of circumstances which would compel him to do so. Apprentice must, perhaps, in like manner sacrifice future advantage to present need, being entirely self dependent for personal wants, and he is likely to set himself up as a jour for the sake of increased wages and a possible social advance before his mechanical attainments would justify the move. If he has—notwithstanding the hindrances which may be mentioned later—succeeded in mastering the rudiments so as to do a common easy job, he offers himself at some new place and stays there until some work outside of his experience is to be done, when the boss either cuts him down or compels him to move on to repeat the operation in other places. We can imagine a trade picked up in this way as a rolling snow ball increases by motion, but at best it would be a pieced-up matter. Student on the other hand, having present living provided for, could afford to remain under instruction for a time not contingent upon the market value of his services.

Employers are responsible also for the lack of complete workmen, because of their special devotion to self interest manifested in keeping the apprentice in a position and at work which is most profitable to the boss, even though such work may seem to have no connection with the trade proposed to be learned. In the old time when a boy was "bound apprentice" and compelled to serve the term of his indenture, there was a corresponding obligation on the part of the employer to keep and teach him the "art and mystery" of a trade. Nowadays it is a mystery if a boy fully acquires the art he commences.

Another point to be noticed is the composite nature of the modern sheet metal business obliging employers to hire "all around" men as the "want column" puts it. The average "tinner" (an elastic title) has such a variety of work now considered legitimate that he seeks for a condensation of several artisans under one man's hat, like one of those tools for all uses.

Doubtless there are many mechanics who can turn their hands to any job required of them, but as a rule life is too short for a man to become first-class in every one of the lines and it is not strange if the "Jacks of all Trades," &c., &c., multiply on the face of the earth. However that style of do-everything-you-want work has come to stay and workmen must adapt themselves to it. Fortunately trade publications, if not trade schools are in reach of all, so that the progressing mechanic, if he will, may learn the theory. Whether he becomes practical depends somewhat on matters noted above, but largely on himself.

THE LETTER BOX.

Warming a Church.

From J. R., *Cincinnati, Ohio.*—Seeing the church plan of "W. D.," Oxford, N.S., and your comments on it in *The Metal Worker* of April 15, I thought I would like to give my opinion and learn what I could from the Letter Box criticisms on it. The plan seems to give all required dimensions except the hight of the ceiling in the audience room, the depth of the cellar and the hight of the furnace. From the plan it is fair to assume that the church in question is not exactly modern, consequently an average hight of ceiling would be about 18 feet and the cellar not over 6½ feet, and the furnace at least 5½ feet, to the top of the brick casing. These have seemed to me to be near enough correct to adopt in forming an opinion. As the entrance of the church is at the coldest end and where the air pressure is greatest, the furnace should be located at least 10 feet further that way. The length of a hot-air pipe to be practicable depends on the sharpness of the pitch it has, and if my conclusion as to the depth of cellar is correct, the pipes would have to be taken out of the side of the furnace to get a rise of 1 foot in 25 feet, which is not enough, as it should be at least an inch to the foot in runs of half that length and twice as much in runs of this length. To run a pipe at so little pitch due north or west such a distance, means that the air will move so slowly that it will cool to the extent of inefficiency before it arrives at the register. To run a pipe to the extreme south or east wall is unnecessary, for as soon as the air gets through the register it will move to that part of the building at once. So it seems to me that the intentions, which are to distribute the air, are killed by the manner in which they are carried out.

All of the cold-air ducts are too small; those from the church should have a capacity equal to the heat pipes and that from out of doors equal to three-fourths of their capacity. If the furnace burns well and heats up promptly the smoke pipe is not open to criticism, though many might wish it covered. I think the hot-air pipes should be made 14 inches in diameter, with registers whose faces have an area one-third greater than that of the pipe. The registers should be moved so as to shorten the pipes, and if still placed in the side aisles those at the front should be brought 10 feet back from where they now are and those at the other end be brought at least 20 feet further toward the front. If the pipes are shortened in this way and the expense of enlarging them is to be avoided, the pipe that is left after shortening them should be used to run to additional registers in the middle aisle; the pipe leading toward the front should not be over 10 feet long and the pipe running in the opposite direction 15 or 18 feet long. The cold-air duct coming from the side of so long a building will generally have a current of air blowing across its mouth and air may at times be drawn out, while seldom forcing directly in, so that the furnace will not be properly supplied with air. To overcome this, at the mouth of the duct a board should be set up opposite to it and 2 feet away, and the space at the top covered from it to the building. To the outer upright board should be loosely hinged a valve long enough to swing and reach either side of the opening of the duct. This would prevent the air passing the air duct without entering, no matter how the wind blew, and would prevent the wind blowing directly into it.

Air supply, location of furnace, length of heat pipes, their lack of pitch and the wrong location of registers are all open to criticism in my opinion, and I hold myself open to criticism.

From F. H. J., *Rochester, N. Y.*—In answer to "W. D.," Oxford. N. S., whose letter about heating a church appeared in *The Metal Worker* of April 15, I would advise him to dispense entirely with all hot-air pipes in the cellar and take the heat direct from the top of the furnace through a large round register. He will find he can heat the church without any trouble by this method. The hot-air pipes are altogether too long as shown in his plan, for by the time the hot air travels through their length it gets considerably cooled. I heated a church in a country town some five years ago, the size of the building being 30 x 80 feet and 14 feet high. I put a good solid cast-iron furnace with 25-inch fire pot in the cellar so all the heat came out of the top of the furnace in the center of the middle aisle. I did not use a cold-air box, but set up the furnace about 6 inches from the cellar bottom. That furnace gave the very best results, besides costing considerably less. Not far from this same church is a brick church, which has four leaders from the furnace, but it never gave satisfaction. The trustees are now contemplating having it changed and the heat taken from the top of the furnace.

Retinning Sap Buckets.

From Q., *St. Johnsbury, Vt.*—I would like to inquire of the readers of *The Metal Worker* if it would be practicable in a country tin shop, in the manufacture of tin sap buckets for maple sugar making, to make the buckets all but the soldering, and then have a tinning pot to immerse the buckets in, thereby filling the seams with tin and at the same time joining the metal turned over the wire. Thus the "soldering" would all be done at one operation, in place of doing it by the usual method with the soldering coppers.

Note.—If the operation of retinning the sap buckets was skillfully performed, it is probable the result would be satisfactory as far as the quality of work was concerned, but it is doubtful if the articles can be retinned as cheaply as they can be soldered in the usual manner.

Crucibles for Melting Brass.

From R. A. R., *Hiawatha, Kan.*—Can I be informed through the columns of *The Metal Worker* how to make crucibles for melting brass without the use of fire clay?

Answer.—It would be difficult for our correspondent to make crucibles without fire clay, as the latter is used to a certain extent in their manufacture. Even "black-lead" crucibles are said to be composed in part of fire clay. If our correspondent desires to melt brass it would be best for him to buy the crucibles ready made.

Bending Heavy Plate Steel to Arc of a Circle.

From L. R., *Whitinsville, Mass.*—Please inform me through *The Metal Worker* how to form up a steel plate of No. 10 gauge, 8 inches wide and 40 inches long, to an arc of a circle 52 inches in diameter. I want to form the plate through power rolls, which are 6 inches in diameter, without leaving flat parts at the edges of the plate at the points A or B of the sketch, Fig. 1.

Answer.—Fig. 1 is reproduced from the sketch sent by our correspondent, the points A and B of the edges showing the

Bending Heavy Plate Steel to Arc of a Circle.
Fig. 1.—Showing Curve with Flat Ends.

flat parts usually present when heavy plates are passed through rollers of large size, if the edges are not first turned to the sweep of the circle desired by using a heavy wooden maul for the purpose. It is almost impossible to make a perfect curve by this method, even if done by skillful workmen. A method by which to accomplish the result desired, without the use of a maul or other treatment of the plate before it is formed in the rollers,

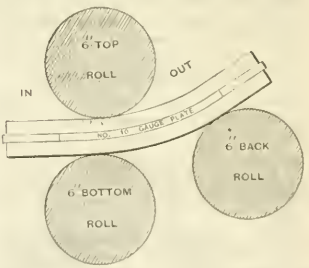

Fig. 2.—Manner of Rolling the Plate to Circular Shape.

is as follows: Place the 8-inch by 40-inch steel plate between two plates of a heavier gauge in the manner shown in Fig. 2. The three plates are shown in the position they bear to each other during the process of forming. The heavier plates must be of the length of the No. 10 gauge plate to be formed and of sufficient width to project beyond the side edges of it a distance somewhat greater than from the points A and B of the plate shown in Fig. 1 to the edges. When rolling the plates, the outside or heavier plates only will be flattened at the start and finish, while the center or lighter plate will form up perfect to the sweep to which the rolls are set.

Quality of Water from Radiator.

From BROOMELL, SCHMIDT & COMPANY, LIMITED, *York, Pa.*—We note the inquiry from "C. R.," Utica, N. Y., in *The Metal Worker* of April 15, in regard to heating bathroom from kitchen range, &c. We have for the last three years been installing our Heatencook range, to which we attach as high as nine radiators, heating the entire house in many cases, and it has been our custom universally to draw all hot water for the house from the heating system. We have never had a single complaint with regard to the water, and we are confident that it will never stain linen, or give any other unpleasant result. We do not, of course, recommend this water for use in cooking, and we do not think water from an ordinary range is ever employed for this purpose.

Sliding Damper Wanted.

From J. C. F., *Williamsburg, Ohio.*—I have a large round stove which is located 28 feet from the chimney. Wishing to secure a good draft when the fire was started or fresh fuel put on, the pipe collar on stove was closed by means of a cap and the 8-inch pipe used connected with an opening of similar size in the top of stove. A common damper was placed in the pipe for regulating the draft, but an objection to its use is that it does not remain in the desired position, being liable to turn. Some years ago I saw a damper that would appear to answer my purpose. It was for a round 8-inch pipe, made box like and provided with slides which could be drawn out as desired. Will the readers of *The Metal Worker* inform me where such a damper can be procured.

Note.—We have seen a damper of the character our correspondent describes, but do not know who makes it. The Richardson & Boynton Company, New York and Chicago, manufacture a sliding damper which is provided with two slides, and is intended for elliptical pipe 6 x 11½ inches, the area being about that of an 8-inch pipe. While our correspondent wishes a damper intended for a round pipe, the above may be made to answer providing he is unable to secure the kind desired.

Pump for Driven Well.

From H. A. C., *Bainbridge, N. Y.*—Do you know of any pump made that will work easily on a driven well with about 25 feet of 1¼-inch pipe? We have a No. 4 common pitcher pump and some of a smaller size, but they all work so hard that they cannot be used except by a very strong man.

Answer.—The lift is somewhat above the practical limit for ordinary pumps, and those of the pitcher variety are hardly qualified for the work. Specially constructed and proportioned pumps, with a powerful leverage greatly in excess of that of the style of pump mentioned, and made for driven wells, can be supplied by any of the large pump houses.

Lining a Tank.

From H. and S., *Marietta, Ohio.*—We have a 60-barrel water tank to line. Which would be the best material to use—copper or lead? What thickness should we use, and how is such work usually done?

Answer.—Either material, in our opinion, would make a good lining for a tank. Sheet lead is more generally used for lining tanks than sheet copper. It is considerable cheaper as to first cost, and is equally as durable under many circumstances, and can be readily worked. These considerations, and also the fact that sheet lead can be procured in sheets of any size, ranging from 3 feet square to sheets about 10 feet wide by 20 feet in length, of any gauge from $\frac{8}{64}$ to $\frac{1}{8}$ inch in thickness, may in this instance recommend it to our correspondent's preference. Sheets either $\frac{1}{16}$ or $\frac{1}{16}$ inch in thickness, weighing 3½ and 4 pounds per square foot, respectively, will be ample for the purpose. Have as few seams as possible, and make the seams or laps tight by the method usually termed lead burning.

Cleaning Solder.

From A. J. T., *Alexandria Bay, N. Y.*—I would like to be informed through the columns of *The Metal Worker* how to clean wiping solder after it becomes foul by wiping on galvanized iron pipe. The solder becomes chalky and brittle, the tin and lead appear to separate, making it difficult to use.

Answer.—The usual method for cleaning solder that contains zinc is to burn sulphur on the surface of the melted solder, stirring it constantly that the zinc in the solder may be brought in contact with the burning sulphur. The resulting dross is to be removed by means of a skimmer. If any of our readers know of a better method we would be glad to hear from them.

The Best Heating System.

From F. S., *Chester, Vt.*—I have read with much interest the different articles on house heating as they have appeared from week to week in *The Metal Worker*, but, as I have little knowledge on the subject, I should like to hear the ideas of practical men as to the best way to heat an ordinary dwelling house. Expense and other things taken into consideration, which is the most desirable way of heating—hot air, hot water or steam? Please ask the question and call for the views of some of our wiser ones for the benefit of one who is ignorant.

Note.—The question propounded by our correspondent is a simple one, but so broad in its bearings that an answer may seem impossible. Nevertheless it is a question that is often asked, and it is one that a man who puts in heating apparatus is called upon to answer very frequently. The generality of house owners have little knowledge of heating apparatus, and are not in a position to compare the several advantages of the three systems mentioned. The dealer who is prepared to put in an apparatus of either kind has, therefore, to supply the information and persuade his customer that one or another is best suited to his purpose. It would be interesting as well as instructive if those who are particularly devoted to each of the different systems will furnish in a brief way the reasons for their preferences. Let the advocate of the hot-air furnace tell why he prefers this older method of heating, pointing out its economy, the supply of fresh air it gives, simplicity, &c. Let the steam man tell what perfect control his apparatus affords, and how it is proof against the cold of the most rigorous winters. He can also explain that the apparatus does not require the attention of an engineer, and otherwise point out its merits. Finally, the hot-water advocate has an excellent opportunity to explain the merits of his pet system. He can show how economical it is in the use of fuel and how, in the opinion of many, it is superior to any form of heating apparatus. He can also tell how easy the regulation of temperature is in the mild weather of spring and fall by the circulation of water at a low temperature. We will be glad to have our readers take advantage of this opportunity and each try, as it were, to persuade our correspondent at Chester, Vt., that the system he advocates is the best.

Trouble with Galvanized Iron Smoke Stacks.

From C. H. H., *Valparaiso, Neb.*—As galvanized iron does not give very good satisfaction when used for smoke stacks on chimneys in this part of the country, I would like to know if there is anything better for the purpose which is not too expensive. The acid from the smoke seems to corrode the galvanized iron, and from one to three years is the usual time they will last.

Note.—We know of no material of equal cost which would be better for smoke stacks on chimneys than galvanized iron provided a heavier gauge is used than is ordinarily put in such stacks. In most instances they are made too light; No. 27 iron is used where No. 20 or even iron of a heavier gauge should be used to give reasonable satisfaction. Heavy black iron coated with coal tar will under some conditions give good results.

Adjustable Pot Covers.

From J. T. T., *Joliet, Ill.*—In reply to the inquiry of "T. E. S.," Bay City, Mich., that appeared in *The Metal Worker* of April 1, I would advise him to write to Topliff & Ely, Elyria, Ohio.

Mechanics' and Traders' Exchange.

The formal opening of the new rooms of the Mechanics' and Traders' Exchange of this city occurred on the afternoon of Monday, April 10, with appropriate ceremonies. The new quarters are located at 289 Fourth avenue, in the Kennedy Building, and consist of an exchange room, consulting rooms, secretary's office and library, all of which are finished in oak and handsomely furnished. The work of fitting up has been in charge of Stephen M. Wright, the genial secretary of the exchange. At the opening ceremonies a large number of representative builders and dealers in building materials, as well as those connected with allied industries, were present. Addresses were made by Ira G. Hersey, president of National Association of Builders; William H. Sayward, secretary of the same association; J. S. Stevens, ex-president of the Philadelphia Builders' Exchange; John H. Tucker, president of the Building Trades Club; Isaac A. Hopper, Andrew J. Campbell and William C. Smith.

In the evening of the same day the Building Trades Club tendered at their handsome clubhouse, 117 East Twenty-third street, a reception to the president and secretary of the National Association of Builders. The programme consisted of music by Young's Orchestra, followed by a number of special features, including character and humorous songs, recitations and legerdemain. Following the musical and literary features, refreshments were served in the rooms on the main floor of the building. The entertainment was carried out in the same liberal spirit which has characterized the affairs of the Building Trades Club since its organization.

WORLD'S FAIR NOTES.

Pushing Preparatory Work.

According to the closest possible estimates, 15,000 men went to work at Jackson Park last week—an increase of more than 1100 over the strongest force that has been inside the gates since dedication. Director of Works Burnham was in a very comfortable frame of mind over the settlement of labor troubles and the subsequent increased activity in all the construction and installation forces. "We have a full force in the department of works," he said in answer to a query, "and are moving along all right. I should say we had 3000 men of our own besides the labor employed by contractors on Exposition work. That includes the landscape, installation, color and carpentry divisions. The contractors have all their old men back and a good many more besides. It would be hard to say without an actual count just how many men are at work inside the fence and on the Plaisance, but it is enough to make things move along at a lively pace." Mr. Burnham's cheerful view of the situation was shared by the contractors and the returned strikers as well. One of the union employers made an estimate that showed a complement of nearly 15,000 men in all grades of labor, both union and non-union.

Exhibits Received Until April 30.

Director General Davis has issued the following general order :

"Notice is hereby given transportation companies and exhibitors in the World's Columbian Exposition that all exhibits for which permits for space have been issued and which can be delivered and placed in position and the exhibitor's work completed on or before April 30, 1893, will be admitted, and the regulation fixing April 10, 1893, as the last day on which exhibits will be received is hereby modified to that extent."

The original regulation modified by this extension, provided for the forfeiture of all space not occupied by the holder of the allotment by April 10. It has been apparent for some time that some of the exhibitors, notably in those departments where installation has been delayed by leaking roofs, would have to be given that time or else suffer injustice by forfeiture of the apportionment. The time fixed for installation, April 10, was made early enough to provide for the emergency that has arisen. "The order," said the Director-General, "is only a formal permission for an extension that everybody knew would come during the last weeks of installation. It has been so at every exposition and we expected it here. It does not mean that the exhibits are unexpectedly slow in arriving, as some might construe it, for we are considerably in advance of the stage they had reached at Paris or the Centennial 20 days before the opening. We did not want any exhibitor to feel that he would be barred from participation because he had been delayed beyond the time set for him to be here. So far as may be judged this far before the opening, the work of installation is very well advanced and is progressing well. In manufactures alone 15,000 packages have been received and placed in the proper space, and that is perhaps the best test of progress, because the exhibitors of the department were comparatively late getting their official allotments. In agriculture, mines, electricity, transportation, fine arts, floriculture and horticulture exhibits are coming in very fast, and we see no reason to qualify anything we have said as to our readiness on opening day."

The Mineral Wealth of Iowa to be Illustrated.

Any one who believes Iowa not to be rich in minerals has only to view the exhibit now being erected by that State in the Mines and Mining Building to change his opinion.

The Hawkeye country will occupy 526 square feet of floor space under the stairway at the south end of the building. Although the location will not admit of any ornamental structure, the Iowans are equal to the occasion and propose to fill the space allotted them in a manner highly original and picturesque. The exhibit is divided into three sections: Coal, the technical display and miniature scenes from mines and quarries. The exhibit is being prepared by T. W. Meers of Centerville, and is constructed to satisfy geologists and to please disinterested spectators as well. In the center of the space will be shown an interior of a coal mine. This will contain a loaded coal car and several life-size figures of miners at work. Although the space is only 25 feet deep the perspective is arranged to make the mine appear to extend back several hundred feet. Over the entrance of the "pit" will be the word "Iron" worked out in coal and other minerals. The mouth of the "pit" will be built up of blocks of coal so that the entrance will appear to be through a solid block of bitumen.

On the right of the coal exhibit will be the technical display, including fine specimens of every mineral found in the State. A great store is set by the exhibit of Trenton rock and lead, which took the first medal at New Orleans. On the left will be a reproduction of the Ottumwa mineral palace set upon a pedestal of coal. The pedestal will be divided into squares and each square will contain the name of a mineral county in letters of gold. In this division there will also be a model of an exterior coal mining scene. This is built of black walnut lumber and was contributed by the ladies of Centerville, who were patriotic enough to have engraved upon the model "Iowa" instead of Centerville. A solid block of coal weighing 5000 pounds will be set up in this section, upon which will be printed in gold the Iowa mineral statistics. The ladies of Dubuque have built a grotto out of stalactites and spar, which will be erected at the extreme left of the Hawkeye space. This grotto is also arranged by means of lookingglasses to appear deeper than its actual size warrants, and it is a beautiful creation from a decoration standpoint. It will be fitted up with electric lights and will form one of the features of the exhibit. The different clays, glass, sands, and kaolins will be shown in glass jars. A special exhibit of vitrified brick will be made. Among the counties contributing to the exhibit are Alamakee, Dubuque, Jasper, Sergeant, Red Oak, Webster, Clayton, Eldora and Appanoose. Appanoose has 80 coal mines in operation and furnishes the greater part of the coal used in the exhibit. Many minerals will be shown, including red jasper, Galena limestone, magnesia limestone, iron oxide for manufacturing mineral paint, silica, zinc ore, black jack, and clay for vitrified brick.

Minnesota's Mineral Exhibit.

A feature of the natural wealth of Minnesota which is not fully appreciated will be illustrated by means of a fine display in the department of mines and mining. This exhibit will be under the direction of L. P. Hunt, general superintendent of all the exhibits, and H. B. Moore. These gentlemen have secured specimens of all varieties of ore mined in the State, and each mine that is in operation will have a distinct exhibit. The mineral interests of the State are as yet comparatively little developed, and the gentlemen who have charge of this branch of the exhibit feel that there is an excellent chance in their department to do good work. The iron ore interests of the Vermillion and the Mesabi ranges will constitute the principal features of the display.

An interesting feature of this exhibit will be a miniature mine in full operation, sent from Tower City. This model is about 6 feet high and 4 feet wide, and its object is to demonstrate the method of mining iron ore, showing all the various levels, apparatus pertaining to a mine, and even the miners with their lamps on their heads.

In arranging the exhibit in the Mines and Mining Building the stone work that was necessary was constructed of Minnesota stone, each block being labeled, showing from what quarry it was taken. Good granite and sandstone are plentiful in that State, and with samples from each quarry of prominence placed in practical use the merits of the different grades can easily be seen.

Nicaragua Canal Model.

The great model of the Nicaragua Canal is unpacked and nearly ready for exhibition. It is about 35 feet long and 5 wide, and gives a bird's-eye view of the oceans, mountains, jungles, rivers, lake and harbors, showing the advantages of this route for interoceanic communication.

In order that nothing may be left for the imagination the model is so constructed that water will cover the oceans and lake and fill the canal and river. Standing by the model one may study the formation of the harbor at Greytown, on the Atlantic coast, then follow the canal traversing the swamp lands at sea for ten miles, until it reaches the foot of the coast range. Here it climbs up the hills 100 feet by three locks, entering a series of lagoons on the Limpio and San Francisco rivers, which form natural channels to the great San Juan, the Ohio of Central America.

At this point the Ocho dam will raise the waters of the great river to a level with its source, Lake Nicaragua, giving slack water navigation to the inland sea.

From the lake to the Pacific Ocean the distance is only 12 miles, and the highest pass only 45 feet above the lake level. The canal passes about 4 miles south of the city of Rivas, where Gil Gonzales de Avila first met the natives of Nicaro in 1525, and kept his Spanish soldiers busy for a week baptizing the simple Indians at the edge of the "sweet water sea." About half way to the ocean the ships will enter the artificial lake of Tolo, then go down 110 feet by three locks into the quiet waters of the Pacific at the harbor of Brito.

In the Manufactures Building.

On the mammoth floor of Manufactures Building are collected 34 large groups, or subdivisions, of the department. These are divided into more than 200 classes of leading industries. These figures are given to show the scope of the department, which embraces the entire product of modern machinery and the skillful handiwork of man in every design and form. In finish, and especially in the patient, laborious processes of manual labor, it is conceded that the foreign exhibitors may excel at the World's Fair. But in variety and in originality it is just as certain that the United States exhibit will surpass those of foreign countries. Keen rivalry has led to many competitive exhibits from the leading manufacturers of the United States. The department officials have insisted that each exhibit from domestic houses shall typify some special industry, and that there shall be no huge displays which depend for merit on the amount of space occupied.

Encircling the vast building on all four sides are spaces devoted to offices, restaurants, concessions and the various appliances for public comfort. There are continuous promenades outside in the covered loggia. Every known public convenience, including seats along these promenades,

will be arranged. In the center of the building, along Columbia avenue, there will be a series of elevators to carry passengers to the outside of the main roof, where a promenade balcony will extend on all four sides of the building.

The lighting of the interior at night has been planned on a scale that will astonish even those familiar with modern electric lighting methods. Along Columbia avenue there will be monster chandeliers suspended from the roof trusses. Each of these chandeliers contains a cluster of arc lights. The hight above the floor —about 140 feet—will enable them to throw a brilliant light over all the gallery space and the main part of the lower floor. On the latter, along the various streets and avenues, are a series of arc lights, mainly suspended from the galleries, which will light up all parts of the ground floor. The exhibitors pay for the special lighting of their pavilions and, in many instances, they attain superb artistic effects by a liberal use of the incandescent system.

Most of the exhibits are housed in exquisite pavilions. In some groups this interior architecture observes a prevailing key throughout. Thus in the German exhibit the prevailing style in all the minor booths, as well as the grand façade in front, is the Renaissance of architecture, the rococo decoration being profuse and frequently gorgeous. In the French exhibit, on the section diagonally opposite the German exhibit, the style of architecture is severely classic throughout. The arches and columns in every portion of the French section show a uniformity of design and great *finesse* in execution. In the English section and also the United States section this uniformity of design in the pavilions is lacking, although there are many individual structures of great beauty.

The Germans and French have built their structures under direct governmental supervision and with government moneys. The United States exhibitors, on the other hand, have had no concert of action, and there is little uniformity of design in the installation of exhibits, except in so far as the exposition officials could prevail upon individual exhibitors to build pavilions and install exhibits in a compact and striking way. The foreign commissioners subordinate individual exhibitors to a general plan, but the Americans have yet to learn this method of installation and the necessity of providing money to carry it out successfully.

The quadrangle formed by the American, German, French and British sections on the ground floor has a central point, where all four meet. This point is exactly in the center of the building. Between the various façades which form the initial point for entering each of these sections there is a central court. Within this court rises the crowning spectacular exhibit of the entire building. This is a highly ornamental tower of staff work, built by Nelson Brothers and designed by Sanier for the exposition authorities. Near the top of this tower will be placed the master clock of the exposition, which is an exhibit by the Self-Winding Electric Clock Company of New York. There will also be a chime of bells, which will ring out the hours.

The northeast section of this central court is occupied by the most pretentious structure containing a United States exhibit. This is built by three New York firms—Tiffany & Co., the Gorham Mfg. Company and the Tiffany Glass & Decorating Company. The architecture is Doric, the color being white, with gold ornamentation. There is a curved façade, and the building itself is about 25 feet high. From the center of the front there rises a Doric column, surmounted by a globe and crowned by an eagle 100 feet above the floor. There are two lesser columns 40 feet high on either side, and wide arches between the columns which span the entrances to the interior exhibits of jewels, gold and silverware. At the base of the main shaft is a pedestal with an inscription which declares that this section of the building is devoted to United States exhibits. The ornamentation and symbolism are all emblematic of America.

The pavilions erected by the Hindostanese and the Ceylonese are the admiration of all who see them. No such specimens of wood carving were ever before seen in this country. Delicate tracery and carving in satin woods and ebony are profusely used to ornament the columns and arches. The wood carvings which will be shown in the interior exhibits from these countries are the products of the most skilled native workmen in either country, and therefore the finest exhibits of their kind in the world.

When the visitor enters the United States section one of the first impressions will be the wondrous variety and comprehensiveness of the manufacturers' exhibit. Before examining the details of the several exhibits the visitor will be well repaid for a study of the exterior ornamentation of the several booths and pavilions. Perhaps the most exquisite of all the American pavilions, from an artistic point of view, are those of the Pairpoot Mfg. Company and the Meriden Britannia Company, both being exhibitors of silverware. The Pairpoint pavilion is a miniature Grecian temple, pure white in color, its splendid proportions being a model of classic architecture. The Meriden pavilion is circular in shape and constructed entirely of rosewood. Other very handsome pavilions in the American sections are those of Edward Jansen, who exhibits toys in the gallery, and Mermod & Jackquard, who exhibit jewelry, also in the gallery. These are gems in the Renaissance style of architecture. There are many Byzantine kiosks and other miniatures of ancient structures in various portions of the American sections.

There are also several collective exhibits in the department of manufactures. Among the more striking of these may be mentioned the exhibits of the National Association of Woolen Manufacturers, the Association of Silk Manufacturers of the United States, the National Pottery Association, the Wall Paper Manufacturers, the Merchant Tailors' Association and the Shoe and Leather Association. The two last mentioned exhibits are outside of Manufactures Building in special structures. The merchant tailors' exhibit is in an artistic building between the Art Galleries and the Illinois State Buildings, and faces the northwest lagoon. The interior decoration of the Merchant Tailors' Building is magnificent. There are panels with water color paintings by distinguished artists, typifying six stages of dress from the time of Adam to the present day. The other overflow exhibit—shoe and leather—is in the southeast portion of the grounds. This building is 570 feet long by 150 feet wide, and cost more than $100,000. It will contain the domestic exhibits of leather, boots and shoes, rubber boots and shoes and the allied trades, besides the exhibits of leather from foreign countries.

House of Many Woods.

Oregon has adopted a unique and practical method of displaying the woods produced in that State. At Jackson Park there is now being erected a house constructed entirely of Oregon woods. It is to be 10 feet square and 19 feet high, and will be surmounted by an open cupola. The body of the structure will be of yellow pine. The roof, which will be of red cedar shingles, will be supported by four Doric columns. The columns are of maple and are very richly carved. The roof of the cupola will also be supported by four small Doric columns of carved oak. The exterior will be furnished with panel work containing about all the woods of the State, among which are manzanita, madrone, yew, laurel, myrtle, ash, maple, oak, spruce, balm, fir, sugar pine, bird's-eye pine, cherry, curly maple and alder. The house will form the Oregon pavilion in the Forestry Building.

Honoring Mr. Dredge.

At the session of the Board of Directors on the 13th inst. the following preamble and resolutions were adopted :

Whereas, James Dredge, Esq , of London, England, has, from the inauguration of the work of preparation for holding the World's Columbian Exposition, rendered invaluable service, both in Great Britain and on the Continent, in making known its plan and scope, with which he was at pains to make himself thoroughly familiar, giving to the enterprise the influence of his eminent professional knowledge and experience as an engineer and journalist, thus aiding substantially in securing the participation in said International Exposition by the governments and peoples of Europe ; therefore, in testimony of our high appreciation of the services so rendered, be it

Resolved, That the thanks of this body are due and are hereby tendered to James Dredge, Esq., for his able and continued efforts in promoting the interests of the World's Columbian Exposition ; be it further

Resolved, That an engrossed copy of the foregoing preamble and resolutions, duly authenticated, be forwarded to Mr. Dredge.

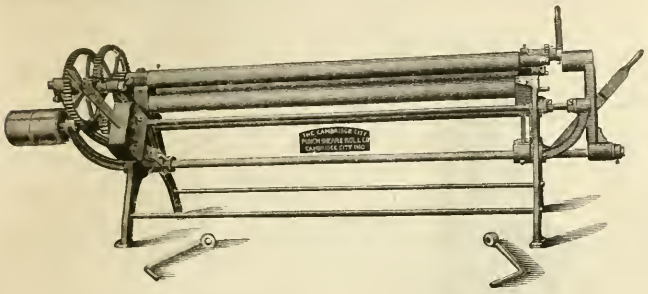
Oil Lamps and Stoves in England.

At a meeting of the Edinburgh Association of Science and Arts, held on March 21, John Laing of London read an interesting paper on "The Burning of Oils in Lamps and Stoves with Safety." As reported by an English paper he said that when gas was of so bad a quality and so high a price, the public generally ought to know that oil was cheaper, and produced a purer atmosphere than gas. Every nation seemed to be alive to public safety but Britain. Americans laughed at the British, and sent over the oils that were unfit for use, and that they would not use themselves. He then showed how the dangers from oil-lamps could be reduced to a minimum. He was strongly of opinion that the present legal flash point was far too low, and thought that 100° should be the minimum flash point of all oils used in the United Kingdom. It was the duty of the Government, he contended, to see that the general public had the same margin of safety as they claimed for the War Office and for lighthouse purposes. Mr. Laing recommended that all oil-fonts and burning lamps should be surrounded by an outer vessel containing cold water. The water could be changed at any time by a simple arrangement without disturbing the lamp. He believed that the majority of lamp accidents were not due to explosions, but the over-turning of lamps and the oil catching fire from the burning wick. If an efficient extinguisher had been attached to the overturned lamp there would have been no danger.

The fleet of vessels wintering in Chicago which have loaded cargoes of grain or which will do so is larger than that of any previous year. Capacity for nearly 9,000,000 bushels of grain has been chartered and when loads for many large steamers which have wintered in Milwaukee and which are almost daily arriving have been taken, the total will not be far from 10,000,000 bushels.

Quick Adjustable Slip-Forming Rolls.

The accompanying illustrations show the new quick-adjustable slip-forming rolls which have just been brought out by the Cambridge City Punch, Shear & Roll Company, Cambridge City, Ind. They are made in all sizes for hand or power. Fig. 1 shows the machine with the roll open, while Fig. 2 shows it with the roll closed. The manufacturers refer to the special advantages of this machine, and in describing it say that the top rolls remain stationary, giving a full bearing box at either end, as well as full bearing gearing. The lower roll works automatically with the weight and lever. By raising the weight the roll is dropped, as shown in



Quick Adjustable Slip Forming Rolls.—Fig. 1.—Machine with Roll Open.

Fig. 1, so that the metal can be easily removed. The rolls are always ready to receive any thickness of metal which permits the rolling of a lap without changing the machine. To remove the metal raise the lever with the weight, pull off post box with lever, turn to one side, and the metal being perfectly loose when the lever is raised can be easily removed. The rear or bending roll is provided with a segmental arm at each end, the arm being hinged at a point below and connected with small gears on the shaft above. The shaft is rotated by a lever, and the roll can

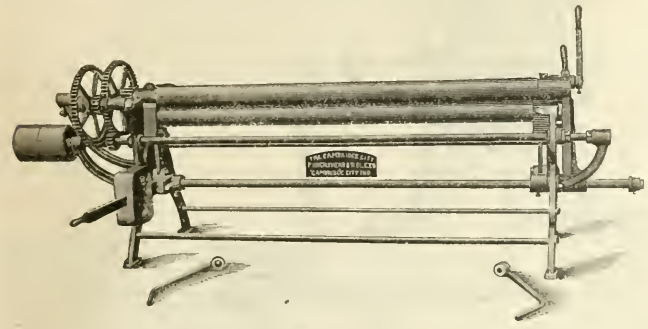


Fig. 2.—Machine with Roll Closed.

be thus moved to roll metal to any circle wanted without the adjustment of any screws. The roll is provided with single or double back gear, and can, it is pointed out, be easily turned by hand. The manufacturers make all sizes and lengths for hand or power.

Instructions to customs officers concerning the collection of statistics of domestic exports to Mexico and Canada have been issued by the Treasury Department. The manifest of the owner or of his agent will be transmitted and delivered to the Collector of Customs at the last port in the United States through which such commodities pass into foreign territory, in such manner as the exporter may elect; but to obviate delay at the frontier port, it is recommended that the manifest be intrusted to the railway or transportation company, to be carried along with the goods.

NEW PUBLICATIONS.

History of the Master Builders' Exchange of the City of Philadelphia, from its organization in the year 1886 to 1893. Compiled for the Historical Committee of the Exchange by Clem. H. Congden. Philadelphia: Sunshine Publishing Company, 1893.

A sumptuous volume of 500 pages, enriched with numerous illustrations and portraits by William W. Morgan, contains an exhaustive history of the Master Builders' Exchange of Philadelphia, an institution which stands as one of the foremost of its kind in the United States and which has made for itself during the seven years of its existence a very prominent position in the business community of the Quaker City. The work is dedicated to Col. Richard T. Auchmuty of New York "in recognition of his generosity and practical interest in the Master Builders' Mechanical Trade Schools of Philadelphia;" a compliment which does honor to the body which offers it as well as to the recipient. The Philadelphia Master Builders' Exchange was the outcome of an idea conceived by Charles H. Reeves, a prominent member of the Master Plasterers' Company of Philadelphia, who in 1886, at a time when the building interests of the city were endangered by labor troubles and excessive competition, presented a plan of organization for those engaged in the building trades to that association for consideration. The scheme met with great encouragement, and in 1887 a charter for the Master Builders' Exchange of Philadelphia was granted. Since then the progress of the institution has been one constant success. A building was acquired in South Seventh street, Philadelphia, which was enlarged and altered to suit the requirements of the Exchange, until it now forms a spacious and handsome structure embracing a permanent builders' exhibition, exchange rooms, offices, café, and every modern feature of convenience and utility for its members. In 1888 a notable feature in connection with the Exchange was the establishment of a mechanical trade school for the manual training of apprentices in crafts connected with the building trades. This departure received substantial support from Colonel Auchmuty, the well-known founder of the New York Trade School, and, next to that institution, it is now the most flourishing and prominent manual training establishment of its kind in the United States. Under the energetic superintendence of W. A. H. Allen, the Philadelphia mechanical trade schools are yearly turning out from their evening classes trained youths whose services are in great request by employers of labor in Philadelphia and its vicinity. The volume just issued gives a full account of this and all the other interests connected with the Builders' Exchange. It is, moreover, as we have said, enriched with a profusion of excellent illustrations, including portraits—with accompanying biographies—of prominent members of the Exchange, views exterior and interior of the building, and a beautiful series of reproductions of the habitations of men from prehistoric times down to the present, taken from the specimens exhibited at the Paris Exposition of 1889. The book is altogether one which will be an ornament to any library.

University of Pennsylvania. Catalogue and Announcements, 1892-93. Philadelphia, 1893.

The growth and progress of that remarkable aggregation of educational interests and institutions known as the University of Pennsylvania is well shown in the 350-page year book just issued. The departments of study which can be entered upon by the students are very numerous, including the regular college department, which comprises courses in arts, science, architecture, natural history, finance and economy and music. In addition to these are the separate departments of medicine, law, dentistry, philosophy, veterinary medicine, physical education, archæology, hygiene, anatomy and biology, as well as the graduate department for women. These entail a professorial staff of 255; the students in 1892-93 numbering 2055, of whom more than half were in the departments of medicine and dentistry. The University appears to be in a highly flourishing condition.

A Big Photograph.

A photograph representing a whole line of railroad is something new. European exchanges tell us that Doctor Piassetzky has intimated to the Geographical Society of Paris his intention to shortly visit France, bringing with him a photograph of the Transcaspian Railway 433 feet long, which he took during his travels between Ouzun-Ada and Samarcand. This unique specimen of the photographer's art is, it is stated, a vivid reproduction of the whole country between the Caspian Sea and the ancient capital of Tamerlane. The only difficulty is to find a building large enough to display the monster picture.

The German Patent Office received last year 13,126 applications and granted 5900 patents, as against 12 919 applications and 5550 patents in 1891. Thus 55 per cent. of all the applications, on which fees had been paid, were rejected.

TIN PLATES.

The Mesta Patent Automatic Pickling Machine.

The first machine of thia type was designed by Geo. Mesta of the Leechburg Foundry & Machine Company over a year ago, and was patented on October 18, 1892. The original machine, which was built by the above company, was placed in the tin plate works of Wallace, Banfield & Co., Limited, over a year ago, and has been in successful operation ever since, pickling about 30 tons of plate per day. Recently the same company gave an order for another machine of thia type, and with the two machines they are now pickling the total product of their extensive sheet-mill plant at Irondale, Ohio.

During the past year these machines have been placed in many of the latest American tin-plate works. The largest improved machine is illustrated in the accompanying illustration, in which A represents a vertical cylinder supported by the base B, C the plunger or piston supporting the arms D, to which the crates are attached for carrying the plates to be pickled. G is a vat built up of pine strips 1 inch thick by 6 inches wide, to contain the acid pickling fluid. H is a vat constructed in the same way containing water to wash the plates after they come out of the pickling fluid. K is a piston valve through which steam is transmitted to operate the plunger C in the cylinder A. When the machine is in the position shown in the elevation, the plunger which carries the cross arms and crates can be given a vertical automatic motion of about 10 to 12 inches, thus giving the crates which contain the plates to be pickled and washed a vertical motion in and out of the washing fluids at the rate of from 40 to 50 strokes per minute. After being agitated in this manner from five to ten minutes, the plates in the acid vat are thoroughly pickled and the plates in the water vat are thoroughly washed. By

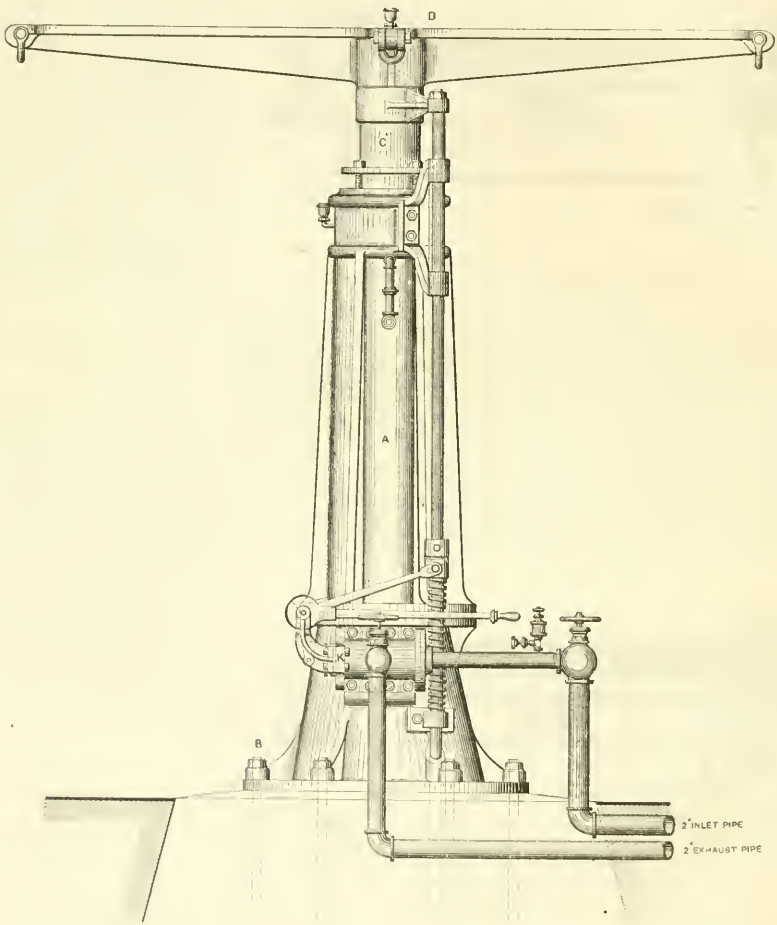

Fig. 1.—Elevation.

THE MESTA PATENT AUTOMATIC PICKLING MACHINE.

means of the hand lever shown on the valve, the plunger can be changed from a short automatic stroke to the long stroke, the full length of the cylinder, which is about 54 inches, thus raising the crates containing the plates out of the washing fluids and above the sides of the vats. Before this is done, however, a third crate is attached to the empty arm, containing a new lot of plates to be pickled; then by revolving the plunger, which can easily be done by hand, as it is revolved on steam which is holding it up in its position, thus reducing the friction to a minimum, the crates, cross arms and plunger are revolved to such a position that the third crate is directly over the acid vat; the crate which was in the acid vat would then be directly over the water vat, and the crate which be dropped from the crate by removing the pin in the lever. The lever can be swung down into almost a horizontal position, thus opening up the bottom of the crate and allowing the plates to drop through.

The advantage of this machine is that the entire machine is supported by one base, which is bolted to a foundation and needs no other attachments to buildings or supports; it is simple in construction and effective in its work, as by no other motion can plates be so thoroughly pickled and washed as by quick vertical motion, dipping the plates in and out of the washing liquids.

The main difficulty at first found with these machines was to get a valve to regulate the flow of steam to the cylinder, and burgh office is in the Germania Bank Building. The Eastern selling agents are H. R. De Milt & Co., 235 Water street, New York; Charles Millar & Son, Utica, N. Y., and Brown, McClure & Wales, Boston, Mass. The circular gives particulars of sizes and gauges of Laufman's Apollo hand redipped and resquared guaranteed plate; also the Tip Top and Allegheny brands, while two pages are devoted to extracts from testimonial letters.

To meet the increased demand for their tin and terne plates, the Phillips Tin Plate Company of Philadelphia have about decided upon a site to which they will shortly remove their plant and enlarge it by the addition of an extra Jenkins Patent tin set and a terne set. These addi-

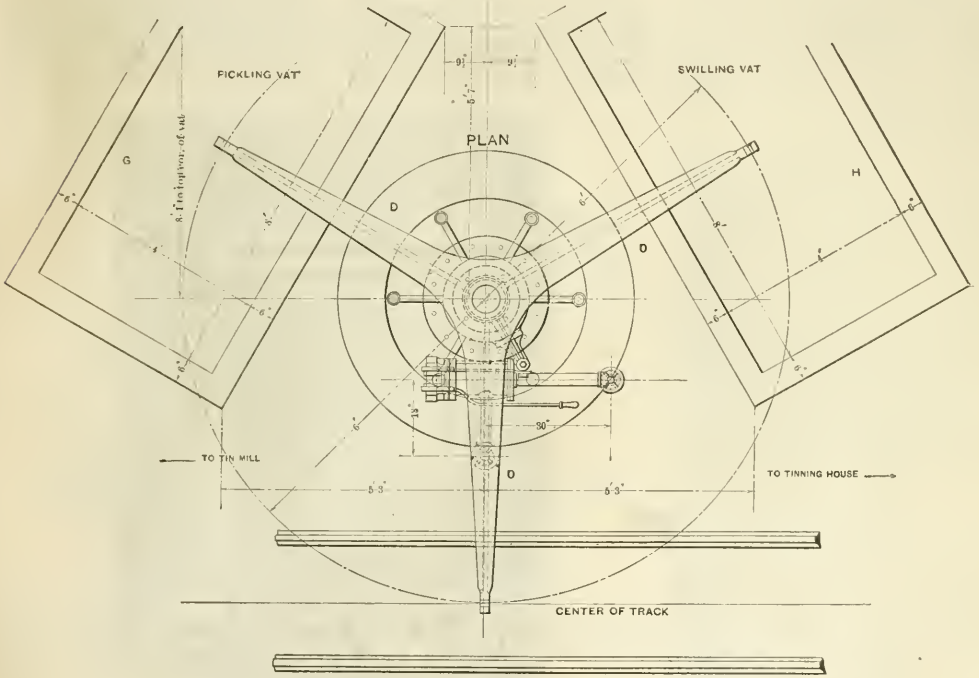

Fig. 2.—Plan.

THE MESTA PATENT AUTOMATIC PICKLING MACHINE.

came out of the water vat would be directly over the track, on which is a truck to receive the washed plates. The plunger is then again lowered and put into the other motion to pickle and wash the plates which are now in the pickling vat and water vat. This operation is continually repeated. The crates to contain the plates are of a new design, and the patent for the same has been applied for. The advantage in this crate over others is that the plates can be dropped through the bottom, instead of lifting them out by hand.

Instead of the crate having a rigid bottom there are six shafts running through the bottom, and on these shafts are small arms, which form the bottom of the crate and prevent the plates from dropping through. At the end of each of these shafts there are small arms keyed to the shaft, and on the end of one shaft there is a lever, to which all of the other arms are attached by means of pins. This lever is held in a vertical position, thus closing the bottom of the crate when the plates are to

that would be economical of steam and not liable to get out of order. This has been overcome entirely by employing a piston valve with a positive motion and cut off.

The new machine which was recently placed in the works of Wallace, Banfield & Co. has one of these valves, which requires only about one half the steam that was necessary to operate the first machines of this type built. This machine was only designed for pickling sheets of tin-plate size, although one is now pickling plates 72 inches in length.

SCRAP.

The Laufman Tin Plate Company, P. H. Laufman proprietor, successors to the Pittsburgh Electro Plating Company, issue a four-page circular relating to tin plates of their manufacture. The works of this concern are at Butler Junction, West Pennsylvania Railroad, with Post Office at Freeport, Pa., while the Pittsburgh office is in the Germania Bank Building.

A Seattle, Wash., mining journal says American tin plate is preferred by consumers in that section to the imported article on account of its intrinsic qualities.

The Falcon Iron & Nail Company of Niles, Ohio, manufacturers of sheet iron and steel, and which concern have just about completed the erection of a large plant for the manufacture of tin and terne plate, have applied for a charter of incorporation under name of the Falcon Tin Plate & Sheet Iron Company, with a capital of $300,000.

The English steamship companies complain that so few passengers are booked in Europe for the World's Fair, while travel from America is less than usual.

PLUMBING AND GAS FITTING.

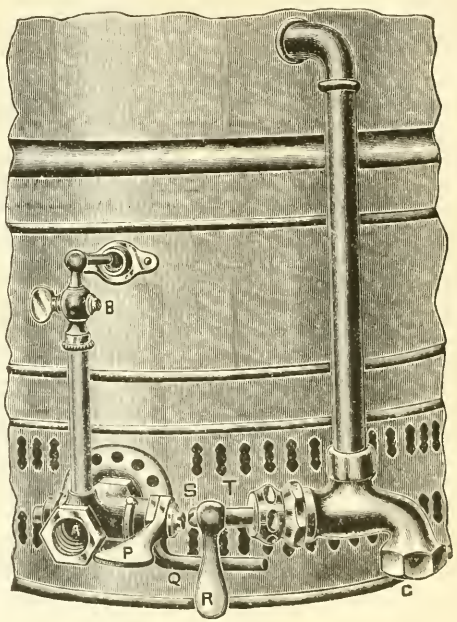
Some Plumbing Questions.

From J. J., *Meriden, Conn.* — Please answer the following questions: In a house here the water closets, washbowls and sinks all run to the main sewer. There are traps under each bowl, but they are not ventilated. The water closets are ventilated to chimney. 1. Will better results be obtained by running ventilation pipe through roof? Would it be any better to take drain pipes from washbowls and run them to a small private drain which there is on the premises instead of to the main sewer as is done at present? Should washbowls be put in a sleeping room?

Answer.—Our correspondent is not as clear as we would wish him to be as to the conditions under which the fixtures are set at present. For instance, we are left to conjecture as to the facilities for sewerage and infer that the soil pipe from water closets and the waste pipes from washbasins and sinks are run in each separate case direct to the main sewer. We are also told that there is a small private sewer, but where it begins or ends has yet to be found out. From the information afforded we give the following as the best answer possible: 1. He will obtain satisfactory results if he runs a vent pipe to above the roof, vents all his traps and carry the vents into said vertical vent pipe. Provided, however, that the work is properly done and the good results expected not neutralized by the fixtures and their traps being improperly set. 2. The proper plan would be to have the soil and waste pipes all discharge into a house drain laid in the cellar and which should be arranged to convey all of the house wastes into the main sewer, if possible. If it be necessary to use the private drain as a connecting conduit between the house drain and sewer it can be done, but whether the house drain discharges into the main sewer or into the private sewer, there should be a disconnecting half S-trap on the house drain inside the front wall, as a sewer-gas cut off. 3. If washbasins are properly set, the traps vented at crown and the vents carried into vertical vent pipe, and the overflow pipe from basin connected with waste pipe between the bowl and the trap, there can be no danger in having washbasins set in bedrooms if the water seal be maintained in the traps. It is better to have no wood work around them, as the closet space under washbasins, when inclosed, is used generally for storage of odds and ends, which help to create foul odors, which can be advantageously dispensed with. The venting of the water-closet trap into chimney is bad practice. The function of the vent pipe in a trap is mainly to supply the necessary air to prevent a vacuum being created by the discharge of a column of water through the soil pipe. The currents in a chimney have a tendency to interfere with a prompt response of a descending air column, and it is always advisable that the vent pipe alone be used to furnish the necessary air to traps.

Instantaneous Water Heater.

The Instantaneous Water Heating Company of 141 to 143 Ontario street, Chicago, Ill., have just perfected some improvements in the Douglass and Acme instantaneous water heaters which involve, we understand, the use of duplex valves. The advantages claimed by the manufacturers for these valves are that they overcome the only weak point which experience had shown the heaters to possess, and that was the liability of burning out by turning off the water while the gas was ignited. While such instances were comparatively few and due to the carelessness of the operator, it was a point which the manufacturers considered should be perfected and made to correspond with the heaters in other respects. By means of the duplex valves the objection named is said to be overcome, as with them it is impossible to turn off the water without shutting off the gas, and yet the arrangement is such that the water is entirely independent. The arrangement is such that cold water can be had without igniting the gas, and when hot water is required the temperature can be regulated to any degree, the same as if the connections were entirely separate from each other. The illustration presented herewith shows that portion of the heater to which the duplex valves are connected. After lighting the pilot B the gas lever P is raised, which automatically turns on the water by means of the bar Q coming in contact with the water lever R. By this means the gas is turned on full and ignited, while there is only a partial flow of the water. The lever R is then turned toward the heater to allow the desired quantity of water to enter, in order to bring the temperature to the degree desired. When the heater is not in use the gas is turned off during the action of shutting off the water. We are informed that the valves can be placed on all heaters in use and will be sold where such a change is desired.



Instantaneous Water Heater.

Determining Grade of House Drain and Sewer.

Few features of a house-plumbing system cause so much annoyance in many particulars as the laying of the house drain in cellar and the house sewer—that is, the connecting branch between the house drain and the main sewer in street. Where ordinary care and forethought are exercised this part of the business presents no difficulties, but as these qualities are in a great many instances absent, it is not surprising to find mistakes occurring which are both expensive and embarrassing. We allude to mistakes which are frequently made in determining the proper grade at which the cellar drain should be laid, so as to avoid too great a descent for the depth of the sewer, and in the second place, to keep intact the required head room in the cellar where the pipes are to be laid under the floor. For instance, a plumber takes a contract to do the plumb-

ing and drainage in a factory or building where every inch of space in the cellar is to be utilized. The architect desires as great a fall to the drain as possible, and the plumber proceeds to lay his pipe from the street sewer to the house. By the time he reaches the front wall, perhaps he finds that if he keeps up that grade back to the rear of the cellar he will be above the floor; and as that is contrary to the specifications he has to choose another grade. This involves loss of time and money, and the question which it brings up is: How can it be avoided? In a very simple manner, viz., by ascertaining at the outset the best grade possible, particularly if the house drain is to be laid in a trench under the floor: and how this can be done the following case which recently came under our notice will illustrate:

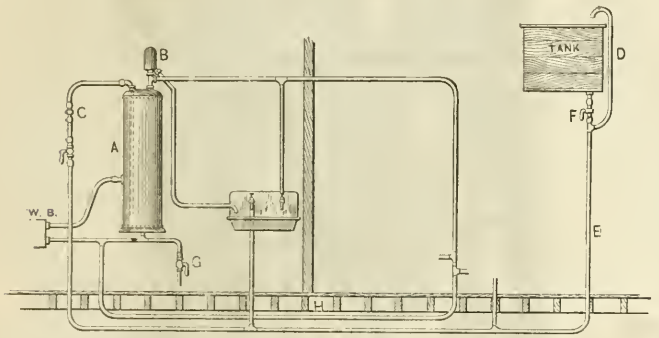
A contractor made an engagement to lay a house drain and sewer without taking the precaution of determining what grade was possible at the outset. After the work had been done in part he discovered his error and proceeded to rectify it, but not without expense. The building was 80 feet in depth, or including 5 feet at rear of building, 85 feet to front wall, and the main sewer was 35 feet distant from the building. This made the entire length of house drain and sewer 120 feet, and the question which then presented itself was, what the grade should be. This was determined as follows: The depth of the sewer in street was first taken and found to be 10 feet below curb level, then the depth of the cellar floor below the curb was found to be 6 feet, leaving 4 feet to be divided up on the 120 feet of drain. This gave an actual uniform fall of $\frac{3}{4}$ inch to the foot or 1 inch in every $2\frac{1}{2}$ feet, which was ample for all purposes.

From this it is apparent that in order to determine the grade of a sewer and house drain it is incumbent to do all of the following, viz.: First, find the depth of sewer in street from curb level, next ascertain the length of sewer and drain from the point of connection with street sewer to the extreme point within the building at which the drain is to begin. Next, if the drain has to be laid in a trench within the building and entirely under the surface of cellar floor, find how much below the curb the cellar floor is to be, and subtract this distance from the depth of the sewer, the difference being the total fall of the drain. Dividing this distance by the length of the drain will give the grade or fall per foot.

Range Boiler Emptied Through Relief Pipe.

From S. I. D., *Canada.*—I have noticed that "C. Q. A.," Ohio, in your issue of March 18, is in trouble. I send herewith a sketch showing a method of arranging his pipes that will obviate his difficulty, which is what he calls "syphoning" of the water in the range boiler back into the tank through the vent turned over top of tank. This, however, is a misapplication of the term "syphoning." The reason of the water flowing back into the tank through the vent is because of pressure in the range boiler becoming greater than the head of water in tank, due to particles of steam mixed with water trying to escape, and which naturally find an outlet at the vent.

Referring to the sketch herewith, A is the range boiler, B is a combination safety and vacuum valve (a small tube is generally run from this over kitchen sink), C is a check valve to prevent any water backing up into the tank. If this boiler were connected with city pressure water works the check would not be needed. The pipe D allows the water to drain out of the pipe E when the stop F is closed; G is a blow-off to sewer. It will not be necessary in this case to have a small hole drilled in tube running down inside of boiler, as the check C will prevent syphonage. H is the circulating pipe, which allows hot water to be drawn from fixtures immediately. Some of the pipes are shown running beneath the floor, but it should be avoided where practicable. It is much better to have all pipes exposed. They can be finished nicely in white and bronze so they will not be at all unsightly and it will materially lessen the plumbers' bills for repair work, as pipes are often almost inaccessible when placed beneath floors or within partitions, &c.



Range Boiler Emptied through Relief Pipe.

Profit in Plumber's Work.

From H. F., *Mass.*—I would like to ask the readers of *The Metal Worker* what they consider a fair and legitimate profit to charge on day-work jobs, stock and time in the plumbing business.

NEW YORK PRICES.

Through interviews with the plumbers of New York it is learned that $3.50 is the standard price paid a good plumber. Helpers receive from $3.50 to $6 per week, the average being over $5. The average charge made for a man and helper is $5.50, though some shops only charge $5, while others get $6. The advance charged on the cost of material varies, some are satisfied with as small an advance as 10 per cent. on large jobs, while getting about 25 per cent. advance as an average on work of less size. A general impression exists that the master plumber is poorly paid at the prevailing prices in comparison with what is charged for the labor of the marble cutter, steamfitter and bricklayer, and the desire for a more remunerative return for his services is based on a reasonable foundation. Car fares, candles and such odds and ends are charged as items in bills. As in all trades where bidding on contracts to be awarded is necessary, the percentage of advance on the cost of the materials varies to a surprising extent, leaving room for some fault to be found, particularly where the business methods are not of a close, systematic character. A 10 per cent. advance having proved satisfactory in some special case, a natural tendency is to apply it to other cases, which is demoralizing.

That on many jobs an advance of 25 per cent. is less profitable than in cases like the above is only too true, and while it is conceded that an average advance of 25 per cent. all around would even things up with a satisfactory balance, unfortunately the "evening up" process cannot be considered a certainty. In consequence many plumbers agree that $33\frac{1}{3}$ per cent. should be had if first-class goods in every particular are to be used. In some special cases a greater advance still is necessary and is secured. The methods of keeping time and account of material between the slipshod and the systematic is one of the great causes of a wide difference in both bids and profits. The following represent actual interviews with prominent members of the plumbing trade in New York:

Mr. Joint says he wants good strong boys of some intelligence, and such boys cannot live on $3.50 per week, so he pays $6, and soon has profitable help.

Mr. Ladle states that intelligent, reliable, industrious men are worth $3.50, and to have them when he wants them he keeps them all the year.

Mr. Pad is willing on a big job of good new work to turn in all of the material bills and accept 10 per cent. advance on their total as his profit.

Mr. Turnpin thinks in smaller work 25 per cent. is too little advance to be profitable, and that 40 per cent. is not asking too much.

Mr. Scraper says the proper way to figure is to carefully account all items of labor, incidentals and materials and add $33\frac{1}{3}$ per cent. to the total for a bid, or if such a record has been kept of work done, 25 per cent. is safe and fair.

Strange as it may seem, while the end in many cases is almost identical, hardly two of the plumbers visited entertained the same ideas or arrived at their conclusions from the same reasons.

CHICAGO PRICES.

The inquiry was submitted to a Chicago correspondent, who replies as follows: In this city the plumbers receive $3.75 and upward per day of eight hours and the helpers from $3 to $6 per week for same time. I have interviewed a number of prominent Chicago plumbers who furnish the following figures:

Plumber A charges $7 per day for plumber and helper, and $6 for plumber alone. Twenty-five per cent. is considered a reasonable profit to add to cost of material on job work.

Plumber B considers 50 per cent. a fair profit to be added to time on job work, and $33\frac{1}{3}$ per cent. on material. One should take into consideration the time lost in shop, loss of material on jobs, breakage of fixtures, &c. The master plumber must be responsible for the proper working of all fixtures. Price charged per day for plumber and helper, $6.

Plumber C: "The usual price for plumber and helper is 75 cents per hour, but the price should be $1, to cover lost time, car fare, &c. Should add from 25 to $33\frac{1}{3}$ per cent. to cost of material used on job work."

Plumber D charges 75 cents per hour for plumber and helper on job work. The price should be $1 per hour.

Plumber E: "The usual price charged for plumber and helper is $6 per day; for plumber only, $5."

Plumber F charges $6 per day for plumber and helper, and $5 for plumber. "Very little profit at these figures, as there is much lost time."

Plumber G: "The usual price for plumber and helper is $7 per day. On small jobs one should get a profit of 50 per cent. to cover incidentals, and on large jobs from 15 to 25 per cent. A profit of from 25 to 50 per cent. should be added

on material, depending on amount of job."

Plumber H charges 75 cents per hour for plumber and helper, and 60 cents for plumber. Considers the proper price for plumber and helper to be from 90 cents to $1 per hour. Should add 33⅓ per cent. to cost of material used in jobbing.

Plumber I: "The usual price per hour for plumber and helper is 75 cents. This is much too low; the price should be $1 per hour. Add one-third to cost of material used in jobbing for profit."

Plumber J: "Pay plumbers from $3.75 to $4.25 per day, and helpers from $3 to $5 per week. Charge $6 per day for plumber and helper on job work. The profit on material should be from 20 to 40 per cent."

Plumber K: "Price for plumber and helper $7 per day, and for plumber only $6. Should get $1 per hour for plumber and helper. Profit on material used in jobbing should be from 25 to 50 per cent."

Plumber L: "Supposing the cost of material for a certain job to be $100 and the labor estimated at $40. A profit of 25 per cent. on the above would be $35, which is none too much."

The general opinion among those interviewed is that the prices charged for job work are much too low. Taking into consideration the high rents paid and the numerous incidental expenses, as cost of collecting, office expenses, lost time, teaming, car fare, gasoline, candles, &c., there is little if any profit left for the master plumber. Take, for example, the matter of lost time. In "ye olden time" there was always plenty of shop work to do, such as making traps, bends, &c., but now all is changed, as almost every article required by the plumber can be bought ready-made, consequently there is little work to keep the men at when in the shop. Customers are liable to grumble if charges are made for such items as candles, car fare or gasoline, yet these must be paid for by some one, and that one is usually the master plumber. There is great danger of breakage of earthen closets, basins and bathtubs, and when an accident does occur, the master plumber is usually the one who stands the loss. When cutting cast-iron soil pipe, the pieces left are of little use and usually find their way to the scrap pile. In fact there are many items of expense that fall on the master plumber that the customer does not realize.

Lead and Tin Pipe.

From F. B., *Delaware, Ohio.*—Some tinners use block tin pipe instead of lead. What is the difference between the two and why do they prefer to use tin?

Note.—There are two very great differences between block tin and lead pipe. One is the difference in material and the other is the difference in cost. Tin is an expensive metal and solid tin pipes are proportionately costly. They have the great advantage of being practically incorrodible, and there is no danger of lead poisoning where tin pipes are used. So far as safety is concerned they are very much preferred to lead, but the objection, as we intimated above, is their very much greater cost.

TRAPS AND VENTS.

J. F. Dalton, 127 Indiana street, Chicago, has the $25,000 contract for the plumbing, gas fitting and sewerage in the Marshall Field building. Sanitas traps and closets are used throughout the building.

Sealed proposals will be received at the office of the Supervising Architect, Washington, D. C., until April 28, for all the labor and materials required for the general excavation and temporary drainage, including sewer connection, for the United States Post Office building at Haverhill, Mass., in accordance with drawings and specifications, copies of which may be had at the office of the Supervising Architect, Washington, or at the office of the Superintendent at Haverhill.

The Columbus Closet Company, Columbus, Ohio, have about completed their new building located on East avenue of that city and expect to move in about May 1. The new structure is a handsome one of brick and stone, five stories in hight. An entirely new nickel plating outfit will be installed, also new foundry appliances, using natural gas for smelting purposes in connection with the American Gas Furnace Company's apparatus, producing, it is said, the same amount of heat in 40 minutes that usually requires over two hours.

The Walworth Mfg. Company, Boston, Mass., issue a little catalogue and price-list descriptive of the line of goods that they manufacture and handle. A large variety of pipe wrenches, vises, stocks, dies, cutting tools, &c, are illustrated and described. Hall's Patent Trapping Machine is likewise given an extended notice. At the end of the pamphlet are illustrations and price-lists of corporation stops, gate valves and other supplies.

Advancing with the demands of progress in the plumbing trade, E. J. Brady, at 58 Warren street, New York, has just arranged to run his pipe-cutting machinery by power, much to the delight of the ever ambitious and industrious helper.

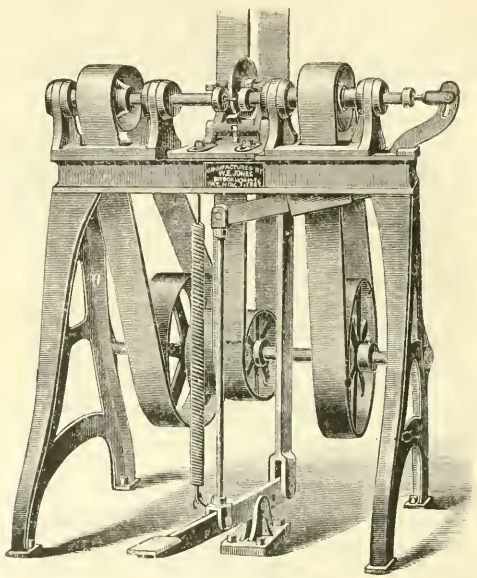
The Walcott-Hurlbut Company, 175-177 Lake street, Chicago, are furnishing 16 nickel-plated showers of a new pattern, also the slop sinks, bathtubs and water closets for the Snell and Beecher halls of the Chicago University. D. F. DeWar & Co. of Englewood, Ill., are the plumbers.

Gay & Culloton, 50-52 North Clark street, Chicago, are doing the plumbing in the German Village, California Building, Arkansas Building, St. Charles Evaporated Cream Company, Agricultural Building and Hayward restaurant at the World's Fair. Also in Colonial Apartment Building, Oglesby avenue and Sixty-third street. Two four-story apartment buildings at Lake avenue and Forty-fourth place; Augustina Hospital, Cleveland and Lincoln avenues; Franchere Hotel, Throop street and Vernon Park, place and residence of J. Taylor at Maplewood, Ill.

Benjamin C. Smith, dealer in plumbers' supplies, sends notices to the trade, under date of April 15, that he has removed to 275 Pearl street, between Fulton and Beekman streets, New York City.

Jones Patent Trimming Machine

The accompanying illustration shows a general view of a machine intended for trimming the ends of covers, dippers and ladle bowls; also for trimming and beading tin boxes, and which is made by W. E. Jones, 14-16 Water street, Brooklyn, N. Y. It will trim and bead from 1 to 8 inches in diameter, and ¼ to 2 inches in depth. One cutting head only, we understand, is necessary for each size, cover or box. This, it is pointed out, saves the expense of chucks. By the pressing of a treadle the revolving disk is brought up to the cutting head, which revolves at the same speed, thus clamping the work firmly, while the large cutting wheel is thrown in doing the trimming by the same movement of the treadle. An inexperienced boy with a little practice can, it is stated, trim from 25,000 to 30,000 daily. The machine requires but one adjustment for all diameters, the slide on which the large cutting wheel is carried being slotted so that it can be moved to suit the cutter to be used. The machine is described as compact and substantial, having steel countershaft 1¼ inch in diameter with two 8 and two 16 inch pulleys driving two 4-inch pulleys, or steel spindles, 1 1/16 inches in diameter, and which run in anti-friction bearings. The weight of the machine is about 300 pounds.



Jones Patent Trimming Machine.

The entire trade between Canada and Australia does not represent much more than the cargo of a single round voyage, and yet, with the aid of a Government subsidy, the plan is to maintain a monthly service between New South Wales and British Columbia. Incidentally Honolulu will be kept in close communication with the British Empire.

Prize Competitions

$25.00.

Prize Competition No. 21.

SUBJECT:

The Safety Line in Credit Business

Among the causes to which the failure of 95 per cent. of business enterprises are attributed, that of extending too large a line of credit is prominent. This competition is designed to draw out from the trade their ideas of the limit beyond which it is deemed unsafe to go in extending credits. Suggestions may be given in regard to this matter, touching upon such points as the following:

Should the definite amount of credit to be given be decided upon at the beginning of the year?

Is this to be fixed at a certain percentage upon the gross sales of the previous year?

Or, should it be an amount proportionate to the stock carried?

Is it better that the amount of credit extended to individual customers depend upon the circumstances at the time?

This competition will remain open until May 13, 1893.

Those intending to compete are reminded that it will not be necessary to write long essays, but that comparatively brief and business-like answers will be favorably regarded as meeting the purpose for which these competitions are announced.

The following prizes will be awarded:

First prize	$12.50
Second prize	7.50
Third prize	5.00

The prizes will be awarded for answers which in the judgment of the committee of award are most suitable for publication and of the most general interest. We reserve the privilege of extending the time on any competition in case the contributions received are not of sufficient number or merit for the committee to award prizes. These competitions are open to every one, and it is hoped that there will be a general response from business men. We shall have the privilege of publishing any or all of the contributions received.

Replies are to be received not later than May 13, 1893. They should be addressed as follows:

DAVID WILLIAMS,
96-102 *Reade street,*
New York.

Prize Competition No. 21.

The committee to whom the contributions in Prize Competition No. 7 were referred have awarded the prizes as follows:

First Prize of $50 to L. A. TURLEY, Boston, Mass.

Second Prize of $25 to WALTER DISCOUNTS, New York, N. Y.

Third Prize of $15 to FRANK KAVANAUGH, Rusk, Cherokee Co., Texas.

Fourth Prize of $10 to W. D. FORREST, Boston, Mass.

Other Competitions which have closed are now in the hands of the Committees of Award, who are giving careful attention to the claims of the different contributions. From the number of these and the evident merit of not a few of them, we are assured that a great deal of valuable information and suggestion will be put at the disposal of the trade.

The Weekly Prize Competitions noted below are now before our readers and remain open until the dates named:

No. 18. Closing April 22.

The Extent to Which Merchants Should Devote Their Attention to Outside Interests.

No. 19. Closing April 29.

Electrical Goods as a part of a Hardware Stock.

No. 20. Closing May 6.

A Reliable System for Securing the Correct Charging of All Goods Sold on Credit.

No. 21. Closing May 13.

The Safety Line in Credit Business.

Another subject will be announced in our next issue.

Cremation of Garbage.

The destruction by fire of city garbage and refuse, where the material cannot otherwise be utilized, has been adopted in many countries with complete success. It has great advantages from a sanitary point of view. A number of cremators have been established in various cities of the United States for this purpose. A plant, consisting of two cremators on the Engle principle, has been lately put into operation in the grounds of the Columbian Exposition at Chicago for the consumption of the miscellaneous garbage from the fair buildings and the sludge from the sewage plant. These cremators have been installed by the Engle Sanitary and Cremation Company of Des Moines, Iowa, who have a number of their furnaces now in operation in the United States and other places on the American continent.

The general principles and mode of construction of the Engle furnaces is described in the *Engineering News* as follows: "The Engle cremator is a rectangular brick structure, with openings in the top through which to feed the material. It has a fire at each end, with the garbage gate between them, so that the smoke and products of combustion from the garbage are thoroughly consumed. Below the garbage grate is a hearth, or pan, which catches and retains all liquid matter, which is then evaporated by the heat of the furnace. When the furnace is charged, the fires are lighted and the flames from the fire next the smoke stack end pass over and through the garbage driving the smoke and gases to the second fire, where they are consumed. The flame and gases then pass over the top and down at the side of the second fire and then through a return flue, which acts as a combustion chamber, under the garbage grate, to the stack. Fire doors and ash-pit doors are provided on the same side of the furnace, and also small doors for stirring the garbage. Part of the garbage grate may be made of tubes, in which water circulates, so that there is a supply of steam and hot water for cleaning and disinfecting the pails, barrels, carts, &c., and for keeping the platform clean. The walls are lined with specially made fire clay blocks, 12 x 9 x 8 inches, laid close and backed by a double brick wall. All openings are protected by fire clay blocks made to shape, and no iron work is exposed to the flame, as in the later furnaces the garbage grate is also of fire brick. On the outside the structure is held firmly together by braces, thrust bars, buck stays and tie rods. The fire doors are carried in iron panels similar to boiler fronts. Carts can discharge their loads directly into the openings. The covering house incloses the cremator and receiving slopes, and this is ventilated into the chimney. The cost of operation ranges from 9 to 17 cents per cubic yard, according to the materials, fuel, &c."

The fuel used in the exposition furnaces is oil, but coal is used in Lowell, Mass., and wood in the cremators at Savannah, Ga., while the furnaces are so built that any fuel or combination of fuels may be utilized. In Savannah two large-sized Engle furnaces built in 1891, consumed during last year an average daily of 135 cubic yards of garbage, including waste and refuse of all kinds, not only house offal, animal and vegetable matter, but straw, leaves, paper, clothing, tinware, &c., at a cost of 13 cents per cubic yard. Night soil, containing large quantities of liquid, was destroyed to the extent of some 50 barrels a day, and withal it was reported by the city Health Board that no offensive smell whatever resulted. The latest garbage cremator built by the Engle Company has been installed at Lowell, Mass. This furnace is destroying from 10 to 12 tons per day of household offal, while its capacity is 30 tons, in addition to 40 cubic yards of combustible refuse and bodies of animals.

The Brass Consolidation.

Work is progressing on the consolidation of the brass and copper rolling mill and manufacturing interests of the Naugatuck Valley. The appraisal of the plants has been nearly completed, but it will take at least a month before the basis for a general agreement can be arrived at. The conditions affecting the industry are peculiarly favorable to a union of interests. The stock ownership of the different plants is largely identical. The same parties are often holders of shares in a number of rival concerns, so that the sharp competition among them is particularly hurtful to this class, which is very influential. To what lengths this competition has gone may be judged from the fact that some time since a contract for 200,000 pounds of trolley wire for Brooklyn was taken at 12½ cents per pound at a time when ingot copper was selling at 12 cents. While this is of course an extensive case, it does not illustrate how competition has cut into the business. The Waterbury brass and copper interests justly boast of having an exceptional record in the harmonious relations between the manufacturers and the workmen, but the former will soon be placed in the position of choosing between the alternatives of a sharp reduction in wages, with a possible conflict, or a consolidation which will put prices on a better level.

One of the peculiarities of the Naugatuck Valley concerns, like Benedict, Burnham & Co., the Waterbury Brass Company, Holmes, Booth & Haydens, Plume & Atwood and the Coe Brass Mfg. Company are capitalized far below the actual investment, the stock issues ranging from $325,000 to $400,000 in a number of cases. In prosperous times the different corporations extended and remodeled their works out of surplus earnings until the actual valuation of the plants ranges from $1,200,000 to $1,800,000. The death, during the past few months, of some of the most prominent men connected with the industry at one time raised some doubts as to whether the undertaking would be proceeded with. It looks now as though it would not be an obstacle. Everything of course depends upon how the report of the appraisers will be received. Even if it does not meet with general approval, it may readily serve as the basis of negotiation which may lead to a final adjustment.

STEAM AND HOT WATER.

Difficulty With Hot-Water Heating.

From F. P. Hamilton, *Cleveland, Ohio.*—In *The Metal Worker* of March 25 is published an illustration of a hot-water problem submitted by "R. B.," Massachusetts. I would suggest to him the advisability of cutting down the fire pot and grate surface to a proper amount to supply radiation. The amount of radiation is not stated, but no concern will put over 50 feet of radiation on ¾-inch pipe. Good practice would not put over 24 feet on a ¾-inch pipe, and then it would have to be much shorter than in the case in question. A 16-inch fire pot as adapted for some hot-water heaters has a rating of supplying 412 feet of radiation. If our friend from Massachusetts will put 1 foot of heating surface for 8 feet of radiation, and a grate of 1 square foot to 30 feet of heating surface, or thereabouts, he will not be troubled with expansion tank overflowing. By this I do not wish to be understood as saying that the tank cannot be made to overflow, for it can by hard firing. He might cut down the amount of heating surface in coil considerably, as there are some hot-water heaters on the market that are rated as high as 20 feet of radiation to 1 foot of heating surface. In short, change the grate to 6¼ inches in diameter, the coil to 6¼ inches heating surface, then the fire pot in proportion, and then observe the amount of fuel consumed as compared with the amount consumed with the present construction.

Key's System of Warming and Ventilation.

The Key system of warming and ventilation, as carried out in the Victoria Hospital, Glasgow, Scotland, is briefly described in the *Sanitary Journal* of Glasgow. Dr. T. G. Nasmyth, District Medical Officer, gives the following details in regard to the system: "In the Victoria Hospital, the incoming air, which passes down a vertical shaft, 16 feet long by 3 feet 2 inches wide, built of white glazed bricks, is driven into the wards by means of two Blackman fans. Each fan is driven by a four-horse power Crossley Gas Engine. From the main air inlet, branches pass to the various wards. Air enters each ward by wide shallow ducts placed along the walls 5 feet above the floor. The incoming air drives out the air which had previously filled the wards through openings at the floor levels. The unique features of the system consist in the air, previous to its discharge into the wards, being filtered, washed and warmed. This is effected by passing the incoming air through a screen made of horse hair and hemp, measuring 16 feet by 12 feet. There is a constant trickling of water down this screen, by which it is kept wet, and the air passing through it is deprived of its dust, soot and other solid particles. An automatic flushing tank discharges 20 gallons of water every hour down the screen, and this removes the dust which has collected in the interval. After passing through the screen, the air is heated (when necessary) by passing through coils of steam-heated pipes. So effectually is the air purified from dust and soot that it is said it has not been necessary to clean the wards for three years, and although fogs are frequently enough found outside the wards, none is ever found inside. The air of the wards is removed six times an hour without producing appreciable drafts. As no fires are necessary in the wards, there is a great saving of labor both from carrying of coals and from cleaning."

The air from the wards has been tested by experts and found to be abnormally free from impurities of any kind.

New Series of Sunray Water Heaters.

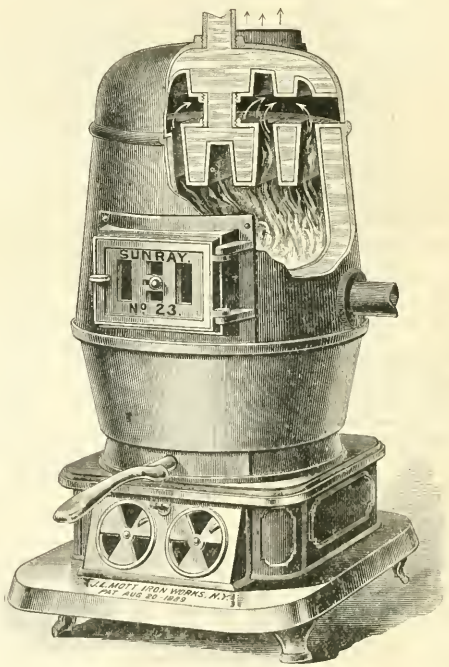
The J. L. Mott Iron Works of New York and Chicago are about to place on the market a new series of water heaters to be known as the Sunray, Nos. 22, 23, 24 and 25. These heaters are designed to heat conservatories and small dwellings, and for heating water for apartment houses, hotels, laundries, bath houses, stables, or wherever a large quantity of hot water is required.

It is said they will heat from 1 to 350 feet of direct radiation, and will supply from 100 to 250 gallons of hot water per hour.

It will be noticed from the illustration that this heater has new features of construction, for which special merits are claimed. The upper part of the cylinder or fire pot is cross-connected with cast-iron tubes that greatly add to its heating power, as well as facilitate the water circulation. In the center of these cross-connecting tubes is formed a collar for a nipple connection to attach the upper section or top of heater. Deflecting plates are introduced between the sections to make the products of combustion traverse the entire heating surface before escaping up the smoke pipe. It is claimed that these features of construction make this a very economical heater.

The heaters are quickly set up, being shipped in two pieces; the base and lower part of the fire pot joining one part, and the water sections the other. No bolt or cement is needed to put them up.

Nos. 22 and 23 are tapped for 2-inch iron pipe, Nos. 24 and 25 for 2½-inch pipe, and all sizes are made with hubs for 3 or 4 inch pipe for greenhouse work.



New Series of Sunray Water Heaters.—Broken View of Heater.

HEATING NOTES.

Mr. Langenberg, representing Barr, Reynolds & Co. of Rochester, N. Y., is busily engaged in installing the steam heating plant at the Mother's Home, at 533 East Eighty-sixth street, New York.

Frederick K. Caswell, Hartford, Conn., is the patentee of a new form of hot-water heater, the idea being to insure a positive circulation of heated water. The principal feature of the apparatus is the circulator, which divides the interior of the boiler into an upper and lower part,

the former being that in which the steam may accumulate, while the water is located in the lower part. The accumulation of steam forces the water to rise within the circulator and prevents any steam from flowing from the steam space into the valve chamber until the level of the water within the boiler has been forced below the lower edge of the circulator.

James R. Vance, Geneva, N. Y., has secured a patent on a steam generator, the object being to arrange the pipes so that increased heating surface will be obtained without increasing the cost of the boiler or impairing its efficiency. The construction is such that the water is confined within a tubular space of no great thickness and both of the outer walls of the tubular space are subjected to the heat from the products of cumbustion.

The New England Engineering Company, 79 Milk street, Boston, Mass., publish in pamphlet form the essay read by O. L. Breckenridge before the Steam and Hot Water Fitters' Association of the United States at their last meeting, on the economy and efficiency of heating by exhaust steam under Andrew G. Paul's patents for removing air.

Robert M. Dixon, East Orange, N. J., is the patentee of an improved form of hot-water heater of a coil pattern. The specifications describe a heater containing three individual systems of coil pipe, each of which is connected outside the heater to the upper and lower connecting chambers, and hence all communicate with one another.

Chas. Weinspach of Fifth avenue and Grand street, New York, is remodeling and enlarging the plant of the Novelty Candy Company (Limited), at Pittsburgh, Pa. A steam system will be used for warming the building, as well as for heating the candy slabs and other manufacturing appliances. The fittings are being furnished and the pipe cut to sketch by John Simmons, New York.

The Jarecki Mfg. Company, Limited, Erie, Pa., issue a very attractive illustrated catalogue of the Erie extension radiators of their manufacture. The catalogue, which is square in shape, contains some 40 pages, and presents numerous illustrations of all descriptions of the Erie extension radiators for steam and hot-water heating. Beginning with a general description of the radiators, the pamphlet proceeds with illustrations of the several styles together with full price-lists, giving dimensions, heating surface and other particulars. Altogether 11 different forms of direct radiators are shown, including corner, stairway, window and dining room radiators. The Erie direct-indirect radiator is likewise illustrated, together with the improved Gold pin indirect. At the close are illustrations of special fittings and pipe threading tools and machines. An attractive feature of the catalogue is the printing, which is done in a red bronze ink.

Russell Wheeler & Son, Utica, N. Y., issue a leaflet addressed specially to architects and engineers, in which they illustrate with sectional and general views the Palace King hot-water heater of their manufacture.

James B. Clow & Son, Lake and Franklin streets, Chicago, are offering to the trade Guillott's metal gaskets for packing all kinds of steam joints, man and hand holes, traps, cylinder heads, steam chests, flanges and unions, tanks, heaters, &c. These gaskets are made of a special metal composition, tempered to stand heat and high pressure, and molded with grooves on the bearing surfaces. The pointed ridges between the grooves make the joint when pressure is applied, working efficiently even on rough castings. They are made in all sizes and shapes.

After a more than tedious illness Geo. B. Cobb has recently been able to make daily visits to his office, and now feels equal to the requirements of business at 42 Duane street, New York. The new signs announce that Geo. B. Cobb & Co. are engaged in the heating and ventilating business where the Pierce, Butler & Pierce Mfg. Company formerly had an agency, and that they make suburban house heating a specialty. The enterprise of the new firm is bringing to them an excellent business.

One of the latest postal travelers issued by the United States Heater Company, which is the new name of the Capitol Heater Company, Detroit, Mich., directs attention to the Capitol and Bolton hot-water heaters and to the Hecla steam heater, and refers to their offices in Chicago and Boston. On the front of the card are a couple of lines from a famous epilogue, slightly varied to apply to the business of the United States Heater Company.

New England Engineering Company, 79 Milk street, Boston, have recently put in Paul's system of heating and drying at the Southworth Paper Mills, Mittineague, Mass., and are working on contracts for Carew and Hampshire Paper Mills at South Hadley Falls, Mass. It is stated that this system dries much larger quantities of paper on a machine than by former methods, and at the same time keeps the cylinder free of water condensed from the steam.

Heating Coil in Hot-Water Tank.

From J. H. C., *Shelburne, Ont.*—Would you kindly inform me what length of 1-inch steam pipe would be required per cubic foot of space in a tank to make water boil (212°)? The tank is oblong, 10 x 4 x 3 feet deep (120 cubic feet). It is placed about 12 feet from engine, and exhaust steam will be used, with boiler gauge at 75 pounds pressure.

Answer.—It is somewhat difficult to give a satisfactory reply to the above query, for the reason that it gives incomplete data as to several essential conditions affecting the calculation. It is clear that any length of pipe which would be sufficient to impart heat to the contained water, in the least degree, more rapidly than would be necessary to make up for the rate of loss from various causes, would eventually cause and maintain the desired temperature of 212°. Presumably, however, this is not the information which our correspondent desires, and it will therefore be necessary to assume the probable conditions under which the heating is to be done. The several factors entering into the calculation, other than those specified, are as follows: 1. The quantity of water in tank; 2, Material of which tank is made; 3, Time allowed for heating; 4, Quantity of heat taken from water, dependent on what purpose it is used for; 5, Temperature of water at starting; 6, Temperature of surrounding atmosphere; 7, Temperature of exhaust steam. We will assume: 1, That, as the total cubic space in tank is 120 cubic feet, and that it will not be filled to the top with the water, an allowance of, say, 3 inches in hight will be necessary. As the area is 10 x 4 feet, or 40 square feet, we must deduct $40 \times \frac{1}{4} = 10$ cubic feet, and our volume of water becomes 110 cubic feet. This, at 212°, weighs 50.82 pounds per cubic foot—say, 60 pounds, and we have $60 \times 110 = 6600$ pounds of water. 2. The tank to be of boiler iron. 3. Time allowed for heating, say 15 minutes or one-quarter hour. 4. Say the tank is to be used for heating feed water for a 20 horse power boiler, which at 30 pounds water per horse-power per hour will require 600 pounds. 5. Initial temperature of water, say 60°. 6. Temperature of the atmosphere, 60°. 7. Temperature of exhaust steam will depend on its pressure in the coil, and this we may fairly assume to be about 3 pounds per square inch, the temperature of which is 222°, or 10° above that required in the water. First, to ascertain the quantity of heat required to raise and maintain the temperature, we have 6600 pounds $\times$ (212° — 60°) = 1,003,200 heat units as the net amount of heat in the water for the difference between 60° and 212°, which must be imparted by the steam in 15 minutes. There will be, also, 600 pounds per hour continually flowing into the tank, requiring $600 \times 152 = 91,200$ heat units per hour. To this must be added the quantity necessary to replace the heat lost, by radiation, &c., from the surfaces of tank, and also by evaporation from surface of water. The combined loss by radiation and contact of air will be about 1 heat unit per square foot per hour for each degree of difference between its temperature and that of the water, or 152°. As we have in two sides, two ends, and bottom, say 125 square feet, the loss will be $1 \times 125 \times 152 = 19,000$ heat units. The loss by evaporation (supposing the tank to be open) will be about $4\frac{1}{3}$ pounds of water per square foot of surface per hour, or $4\frac{1}{3} \times 40 = 173\frac{1}{3}$ pounds. As the latent heat of vaporization, or 966 units per pound, must be added to the 152 units of sensible heat lost, we have $173\frac{1}{3} \times (966 + 152) = 193,787$ heat units per hour, or more than twice as much as is required to raise the sensible heat of the 600 pounds of feed water from 60° to 212°. These three items, then, constitute the total quantity of heat (91,200 + 19,000 + 193,787 = 303,987) necessary to be supplied by the steam coil, to maintain the temperature at 212°, against the above loss. To calculate the length of 1-inch pipe required to furnish this amount we must ascertain, in the first place, the rate of transmission of heat from the steam to the water, bearing in mind that the supply of the former is unlimited, and that, therefore its temperature must remain constant at the degree due to its pressure, which we have found to be 220°. Owing to the high specific heat and great absorbing power of water, the only limit to the transmission from the internal to external surface of pipe will be the conductivity of the iron, the thickness of which is 0.15 inch. Of course, this applies only to pipes so placed as to admit of perfectly free natural circulation of the water, and it is much better to make a liberal allowance on this account than to risk the efficiency of the apparatus. The conductivity of iron is 233 heat units per

square foot per hour for metal 1 inch thick and for each degree of difference in the temperature of the two sides. As the pipe is 0.15-inch thick the amount will be $\frac{233}{0.15} = 1553.3$ heat units. The difference in temperature 222° — 212° = 10° which × 1553.3 = 15,533 units per square foot per hour; and the above number 303,987 ÷ 15,533 = 19.57 square feet of pipe required. The area of 1 foot of 1-inch pipe is about 0.3 square feet and 19.57 ÷ 0.3 = 65.2 feet in length. If we allow 50 per cent. for defective circulation the length will be 97.8, say 12 pipes 8 feet long, connected at both ends by manifolds. This makes (96 ÷ 120) = 0.8 feet pipe for each cubic foot of tank, for the specified proportions of length, depth and width. We have, however, a stated conditon which will render this length of pipe totally inadequate; and that is, the heating of the 6600 pounds of water in the given time—15 minutes. To the quantity of heat previously found necessary for this purpose—1,003,200 heat units—must be added the loss during the time, which, for the mean difference of temperatures, will be 26,526 heat units; and the total heat required from the coil is 1,003,200 + 26,526 = 1,029,726 units. The transmitting power of the pipe—that is, the mean for the given range of temperatures—is found experimentally, to be 343 heat units per square foot per hour, for each degree of difference; and we have (343 × 162) × one quarter hour = 13,892. Then 1,029,726 ÷ 13,892 = 74.12 square feet, or $\frac{74.12}{0.3} = 247.1$ feet of 1-inch pipe; which, with the 50 per cent. allowance = 370.6 feet, say 46 lengths of 8 feet each, or a little over 3 feet for each cubic foot of tank space. Of course it is understood that these figures are only approximate, as it is impossible to calculate exactly, by any known data, the practical results from given conditions. Experimentally, where the utmost care is observed to note and maintain these conditions, the accuracy of results is sufficient to demonstrate the correctness of accepted rules, and in their practical application it is only necessary to make an allowance, not for the method, but for the uncertainties of the existing conditions by which it is affected.

Duty on Pickled Plates.

The Treasury Department issued under date of April 10 the following circular of instructions addressed to the Custom House collectors:

Paragraph 142 of the act of October 1, 1890, imposes certain specific duties on black sheets of iron or steel, according to gauge, and paragraph 144 of said act provides for an additional duty of one-fourth of 1 cent per pound on such as have been "pickled or cleaned by acid, or by any other material or process, or . . . cold rolled, smoothed only, not polished."

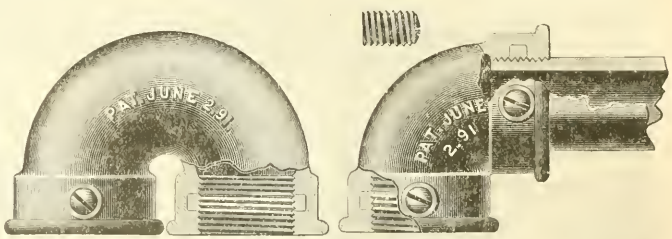
It having been reported that black plates, treated as above described, are being sold in this country at prices which would indicate that they do not pay duty under the proviso in paragrph 144, you are hereby authorized to reject all invoices of such merchandise which bear date on and after the 15th proximo, provided the same do not contain one of the following descriptions: "Pickled or smoothed or cold rolled" or "not pickled or smoothed or cold rolled."

A New Joint for Couplings, Tees, &c.

The Tight Joint Company of 545 West Twenty second street, New York, are putting on the market a new form of joint, applicable to ammonia tees, couplings, return bends, and, in fact, to all kinds of fittings. This joint is similar to an ordinary screw coupling, except that a groove is cast in the threaded portion of the fitting, into which a collar or ring of lead is run. This is formed upon a threaded mandrel of slightly smaller size than the coupling, so that the lead projects a very little beyond the threads. A small hole with a thread cut upon it is made through the exterior of the coupling, into the lead filled recess, and a small set screw is inserted. If now a pipe is screwed into the coupling it will expand the leaden packing, causing it to tightly fill the screw threads, and if the joint is not made tight by this means, one or more turns of the compressing screw crowds the lead around the pipe and makes it absolutely tight.

The tight joint does not leak from unequal expansion and contraction, because the pipe when heated expands the lead packing and fills the recess and the pipe threads. Upon cooling the fitting contracting about the leaden ring forces the lead around the pipe and again makes it tight. In hydraulic systems any loosening of the pipe is readily taken up by the compressing screw

Exhaustive tests made of this joint have proved that it will remain tight under the highest pressures and most trying conditions.



NEW JOINT FOR COUPLINGS, TEES, &c.

The Burn Stamping & Mfg. Company.

An admirably designed plant for the manufacture of milk cans has just been completed by the Burn Stamping & Mfg. Company at Chicago Ridge, 16 miles south of Chicago. The main building of the works is a very substantial four story structure, 200 x 48 feet, with high ceilings and numerous windows. Immediately joining, but separated by a fire wall, are the boiler and engine room and an annealing house. Completely detached from all other buildings is a tinning house.

A noteworthy peculiarity of the company's methods is that they receive all their material in black sheets and do their own tinning, which they find much more satisfactory than to buy tinned stock. The sheets used are of Nos. 18 and 20, as milk cans require unusually heavy tin plate to withstand the rough treatment which they receive. The first floor of the main building is devoted to the heaviest machinery, consisting of stamping presses, welding rolls, squaring shears and a full equipment of tools for making dies. A number of special machines of the company's own design are used for some of the processes through which the material passes. The second and third floors are used for making up milk cans. Tinners' benches extend around the walls and along the center. A gas plant is being installed for the manufacture of gas for both illuminating and soldering. The fourth floor is used for the storage of made-up cans. A large freight elevator serves all floors. The machinery is run by a 65 horse-power Hamilton-Corliss engine. Water is pumped at the rate of 50 gallons per minute from a 110-foot artesian well to a tank on the roof, whence it is distributed through the building. The annealing furnaces are located in a fire-proof compartment and are of large size.

The tinning house is a typical Welsh plant. It is thoroughly fire proof, built of brick and iron. The roof is constructed of I beams, with brick arched between, and even the windows have iron sashes. There are two tinning stacks with brick hoods. One of these stacks is fitted with what is claimed to be the largest pot in the country. It is a Phillips pot, built 20 inches wider than the standard, and will take a sheet 50 x 23 inches. The other stack has five separate dipping pots or kettles, and is of special construction to suit the class of work done by the company.

Another brick building, from 75 to 100 feet long, will shortly be erected as a wing to the main building. The ground floor will be used for storing raw material and the upper floor will be devoted to special work.

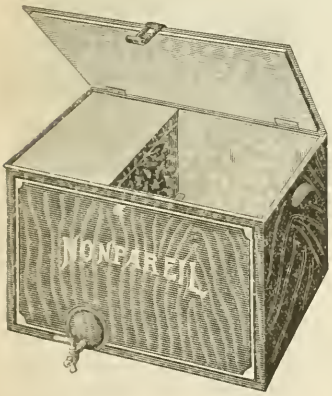
The tract owned by the company comprises 10 acres, thus giving them ample room for expansion. It is situated in an angle formed by the crossing of the Wabash and Calumet Terminal railroads. Side tracks run into the grounds between the buildings, all of which have been built so that their first floors are on a level with freight-car floors, for convenience in receiving and shipping freight. The Calumet Terminal Railroad being a belt line, connection is thus made with all the roads running into Chicago, which insures shipping facilities of the best character.

The leading officers of the company have had long experience with other concerns in the manufacture of the same class of goods, and are therefore undertaking no experiment. It is their intention to manufacture all kinds of milk cans to meet the requirements of this class of trade in any section of the country from the Atlantic to the Pacific coast. Every city uses a special pattern of milk can, and local preferences must be faithfully adhered to in order to secure such trade. While milk cans will constitute the bulk of the company's business, they will also be prepared to do work for those who want special dies made or other work in related lines. Their equipment of machine tools was carefully selected to enable them to meet a demand which is rapidly growing in and about Chicago. Employment is given to between 150 and 200 hands. W. P. Ketcham is president of the company, John T. Dale vice-president, W. S. Burn general manager and superintendent, W. H. Burn secretary and M. J. Higley treasurer. The Chicago office and salesroom are located at 66 Lake street.

THE RETAIL STORE.

Refrigerators for Nurseries or Sick Rooms.

August Kreamer, manufacturer of kitchen and culinary utensils, house furnishing goods, &c., 17–23 South Third street, Brooklyn, N. Y., is making a number of portable refrigerators, which can be supplied at a moderate cost. In the illustration is shown what may be termed a nursery refrigerator, made in a very thorough manner of heavy tin and lined inside with galvanized sheet iron. At the left of the box is a section in which to place ice, a movable tray at the bottom being provided for holding it. The water from the melted ice is easily drawn off by means of the faucet. On the right is seen the space intended for food, milk, medicines, perhaps, or whatever is desired to



Refrigerators for Nursery or Sick Room.

be kept cool. This portion is equally divided into two compartments by a movable tray. The contrivance is expected to supply a want where refrigerators are not available, as in apartments, hotels, hospitals, boarding houses, &c. The refrigerators are made in two sizes. No. 1 is 16 x 12 x 12 inches; No. 2 is 19 x 13 x 13 inches in dimensions. Another pattern is made corresponding with the above description, except that less space is allowed for ice and more for food, &c., while the faucet is placed half way between the top and bottom of the box.

Bread Mixer and Kneader.

The accompanying cut represents the Prescott-Stanyan Bread Mixer and Kneader, which is being introduced by Edwin Prescott, 8 Medford Street, Boston, Mass. It consists of a blade and guard revolved by a crank in a pan, which is set in the frame, the machine being fastened to a shelf or table. After the correct proportions of flour and moistening have been put in the pan the crank is turned and at the same time the pan is rotated slowly by hand until the flour is moistened sufficiently to move the pan itself; after which

Bread Mixer and Kneader.

the pan is prevented from turning too fast by pressing lightly on the edge with one hand. After rising the machine is set in the pan for a second kneading. The guard is to prevent the dough from winding upon the blade, and should be as near the latter as possible, yet not touch. The makers claim that the machine thoroughly cuts and beats up the dough, stretching and rolling it into that elastic condition necessary to produce light, fine-grained bread; that it will save half the time and more than half the labor; that the machine is simple and not liable to get out of order; with no more pieces to clean than the ordinary pan and spoon, and that with the machine a boy or girl 10 or 12 years of age can mix and knead a batch of bread as easily as the strongest and most experienced woman in the old way. The point is made that the machine is equally well adapted for mixing rye, graham, brown bread, fruit cake, &c. Two sizes are now ready—No. 1 with a 7-quart pan, and No. 2 with an 8-quart pan. It is stated that each works best with the pan half full of flour, yet that either will handle a quart more or less.

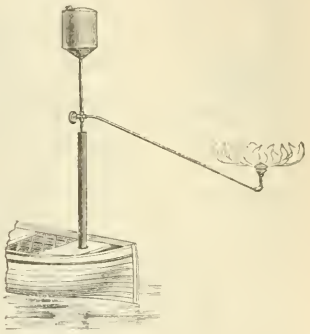
The Gem Cake and Batter Mixer.

North Brothers Mfg. Company, Philadelphia, Pa., are offering this household article as shown herewith. The metal part of the beater consists of steel bands ⅛ inch wide bent and inserted in a wooden handle. The makers claim that being light and convenient, it does not fatigue while being used, and that it does the work rapidly and thoroughly. It is pointed out that one of its important features is the tenderness it imparts to everything beaten with it. The device is intended for mixing all kinds of cake and for beating up batters:

The Gem Cake and Batter Mixer.

The Baker Fishing Lamp.

J. R. Baker & Son, Kendallville, Ind., are offering the above lamp, as shown herewith. The lamps are designed to be used when spearing or gig fishing, taking the place of wood jacks or pine torches. The point is made that with the lamps sparks, smoke, unsteady light, the constant dropping of coals into the water, the preparation of fuel and the frequent stoppages necessary to replenish the fire are annoyances not encountered. The gas-

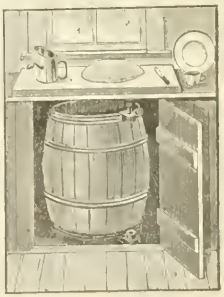


The Baker Fishing Lamp.

burning fishing lamps are made in two sizes, No. 1, as shown in the cut, having a 5-quart tank and one burner; No. 2 has a 6-quart tank and two burners.

The Perfection Barrel Swing.

The barrel swing shown in the accompanying illustration is being introduced by the Leavitt Machine Company, Orange,



The Perfection Barrel Swing.

Mass. The swing is so arranged that barrels can be swung under a broad shelf or counter, leaving the floor room free when the barrel is not in use; and the manufacturers claim that a barrel thus swung can be operated by a child as readily as by a grown person. The swing is adapted for use in the home, also for grocers, hardware and paint dealers, or for any stores using barrels.

Arrangement of Stores

The accompanying illustrations relate to the Hardware establishment of Dayton & Hall, First and Taylor streets, Portland, Ore. The building is of brick and iron, 26 feet front by 110 feet deep, of which the basement,

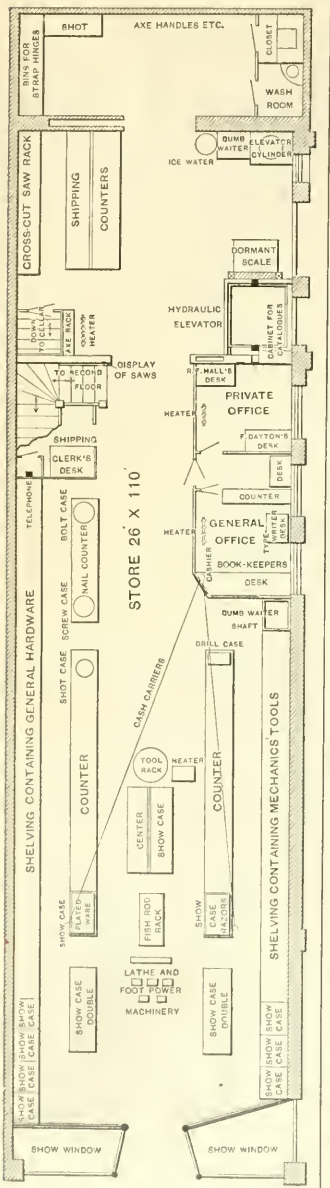


Fig. 1.—Plan of Main Floor.

first, second and third floors are required for the business. The building is handsomely fitted up, with modern improvements, among which electrical appliances are used to a great extent. The building fronts on First street, Taylor street being on the side, thus giving large show windows and fine receiving and shipping facilities. On the Taylor street side is a wooden awning supported by brackets, extending along the rear portion of the building over the wide sidewalk, affording protection for goods temporarily outside the store.

In front of the store at the curb is a Padlock sign, mounted at right angles to the store, on a handsome iron post, the lock being almost an exact copy of the No. 8454 Yale. The post is the Mott Iron Works' No. 39 and is 9½ feet high, finished in maroon and gold. The Padlock is of galvanized iron, 3 feet wide and 4 feet high. The Lock was first painted with red lead and then with two coats of paint, giving it a dead black rustless finish. The name Dayton & Hall, in porcelain letters, 4 inches high, is on both sides of the shackle of the Lock, and the word Hardware is cut out of the body of the Lock with porcelain letters placed back of the galvanized iron. The edges of the Lock and the half balls on the body are covered with gold leaf, the whole Lock being made and finished in the best manner possible. The Lock and post are conspicuous and the firm think an excellent advertisement. The Lock at night is illuminated by electricity, bringing out the word Hardware quite prominently.

From Fig. 1 it will be seen that the store is supplied with basement heater, cash carriers, wall and show cases, Shot, Screw and Bolt cases, bins, dumb waiters, elevators, dormant scale, general and private offices, type-writing machine, shipping desk, washroom, closets, &c. At about two-thirds of the depth of the building partitions run part way across the store dividing the room into two parts—the store proper and the shipping room, where also larger and heavier goods are kept. Fig. 2 shows the gallery, which is suspended from the ceiling of the first floor and reached by the stairway to the second story. This largely increases the capacity of the store; its construction is shown in Fig. 3. On the gallery over the first floor offices are a builder's Hardware sample room and an office.

In the wallcases on the right of the entrance on the main floor are kept stock and samples of fine Tools, novelties and new goods in the Tool line. In the corresponding cases on the opposite side are samples of split bamboo and fine Rods, Telegraph Instruments, Electrical Goods, Dog Collars and other showy articles. On each side of the store, in front of the shelving, are double showcases, one of which is shown in Fig. 3, which are a novel feature, and not only add to the appearance of the room but increase the space for displaying fine goods. In the upper part of the double case, at the right of the entrance, 200 styles of Pocket Knives are kept, while below is a fine display of Builders' Hardware. In the opposite case, the one shown in Fig. 3, the upper part is devoted, in season, to Fishing Tackle, or Cutlery, Novelties, &c., and the lower part to fine Carvers and various attractive goods. Changes are made in the goods and arrangement of these cases from time to time.

The shelving under the gallery on both sides of the store is filled to a convenient hight with wood shelf boxes, sampled, and the two upper shelves are utilized for stock in original packages. On the right-hand side of the store Tools and Builders'

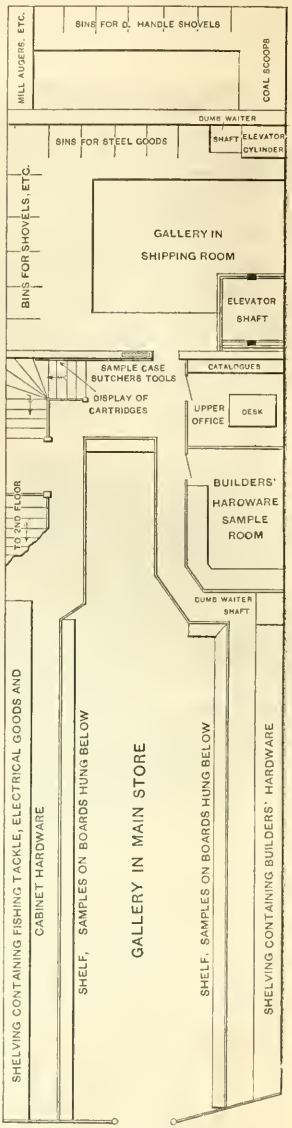

Fig. 2.—Gallery in Main Store.

Hardware are kept, most of the stock of Builders' Hardware, however, being above the gallery. On the opposite side is kept the retail stock of Fishing Tackle, House-Furnishing Goods, Electrical Goods, Cabinet Makers' Supplies, &c. Above the gallery on this side is the larger stock of these goods. Goods are sold both from below and above the gallery, and the gallery shelf is used as a counter for putting goods on. A view of this shelf and the manner in which the under part is utilized for hanging sample boards, is given

in Fig. 4. Samples of Saws are displayed on the front of the partition at the stairway leading to the second story.

The Fishing Rod Rack shown in Fig. 5 during this season stands in the center of the main floor between the double show cases. The legs are of $1\frac{1}{4}$ x $1\frac{7}{8}$ stuff, beaded, with two shelves

Fig. 3.—Showcase, Shelving and Gallery.

2 x 4 feet, held in place by shelf brackets. The top shelf has beaded edges, the whole being finished in natural wood. The top shelf has 38 holes $1\frac{1}{2}$ inches in diameter, and the lower shelf has a cor-

Fig. 5.—Fishing-Rod Rack.

responding number of holes, bored only part way through. This displays a quantity of rods to good advantage in a comparatively small space.

Fig. 6 illustrates a fine show counter recently made for the first floor, on which samples are displayed. The lower part of the counter is 9 feet long and 3 feet high, made of spruce; the top of $\frac{7}{8}$ inch oak, with red wood molding immediately under the top. The front of the partitions are beaded, and the shelves are adjustable. Three-quarter inch gas pipe rests on the top and supports the shelf above,

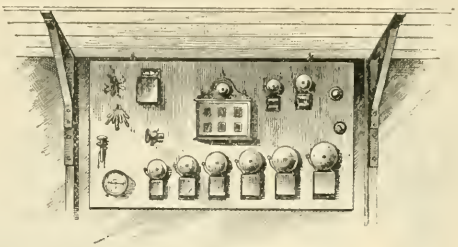

Fig. 4.—Gallery Shelf and Sample Board.

which is of oak 18 inches wide. Above this is another oak shelf 9 inches wide, supported on $\frac{1}{2}$-inch gas pipe uprights. The iron work was furnished by the firm, and the finish moldings, &c., were made to correspond with the shelving, and varnished, oiled, stained, and painted to correspond with the other wood work in the store. The counter was finished in the best possible manner at a cost of $38.

The store is lighted by incandescent lamps, and the clock in the office is self wound by electricity. A complete burglar alarm consists of a large Electric Bell located in the front of the basement, connecting the doors, windows, show-

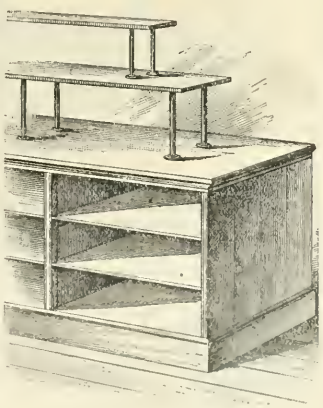

Fig. 6.—Show Counter.

cases, safe, &c., the circuit of which is closed automatically by an electric clock from 11 o'clock p.m. to 6 o'clock a.m. The bell when ringing can be heard by their private watchman a distance of four squares from the building. Electric bells and speaking tubes connect the offices with each floor. The electric lamp at the shipper's desk is controlled by a floor push, while the electric lamp in the telephone closet lights automatically upon entering. The light in the padlock sign, together with those in the show windows and in the store, are under the control of the watchman.

The basement is used for keeping Wire and Steel Nail, Chain, Grindstones, Rope, Grindstone Fixtures, Sash Weights and like heavy goods. A portion of the basement at the rear of the building extends under the sidewalk. Elevator and dumb waiter run from the basement to the other stories. The basement is provided with a sink and the second floor with washroom and closet.

On the second floor is shelving for wholesale stock of general Hardware, Miscellaneous Tools, Cartridges, Wire Brads in papers, wood ornaments, &c. There are also sample counters of Meat Cutters, Coffee Mills, Apple Parers, Scales, Vises, Weather Vanes, and a counter with bins below for Lag Screws, Machine Bolts, Washers, &c. Samples of foot-power machinery are shown on this floor. Clothes Wringers in cases, and cases of Axes, both handled and unhandled, are stored near the elevator.

The front portion of the third floor is occupied as a storeroom for goods in cases, cased machinery, Electric Batteries, Apple Parers, &c. The rear part of this floor has upper and lower bins for the wholesale stock of Shovels and Steel goods. Cases of Cross-cut Saws and Wheelbarrows knocked down are also kept here.

Family Grist Mill.

The Rogers Iron Company, Springfield, Ohio, are offering a farm and ranch family grist mill, mounted in various styles, two of which are shown in the accompanying cuts. They are also made with a bracket to fasten to the wall, and with a low stand to bolt to a table or bench. The

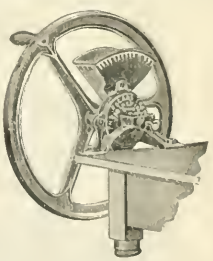

Fig. 1.—Family Grist Mill.

mill is described as having large chilled iron burrs, $4\frac{1}{2}$ inches in diameter, ground perfectly true; the burrs having teeth which cross at angles, insuring rapid grinding. The shaft is of steel, with a fly wheel 20 inches in diameter. It is remarked that the workmanship on the mill is first-class and that all parts are made to duplicate. The mill is adjusted by one thumb screw for different kinds of grinding, and the makers claim it is adapted to

grinding corn, wheat, coffee, spices, or grain of any kind for domestic uses or feeding purposes. The manufacturers state that corn meal, hominy and graham flour may be produced at the operator's home

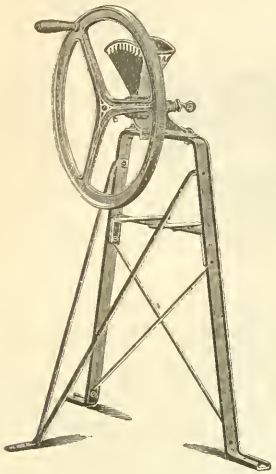

Fig. 2.—Grist Mill With Legs.

fresh and pure; that the mill grinds 1 pound of coffee in one minute, and flour or meal in a longer or shorter time, according as the mill is set to grind fine or coarse.

Torsion Grocers' Balance.

The Springer Torsion Balance Company, 92 Reade street, New York, are putting a grocers' scale on the market, as illustrated in Fig. 1. The balance takes its name from the manner in which the fulcrums twist or "torse." There are no knife edges about the scale, but the beams tip or oscillate upon sensitive steel bands, sprung upon trusses, as shown in Fig. 2. The trusses are first cast and then accurately cut out, so that, it is stated, they do not vary $\frac{1}{1000}$ inch where the bands are placed. After the band is sprung on to the truss, the truss is put under a squeezing machine to expand it equally in all directions from the center. This causes greater tension of the band, and the expansion is continued until the band on the center truss vibrates to the note F sharp. The bands on the end trusses are tuned in the same manner to F. The

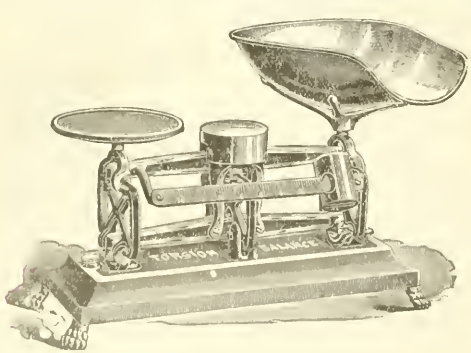

Fig. 1.—Torsion Grocers' Balance.

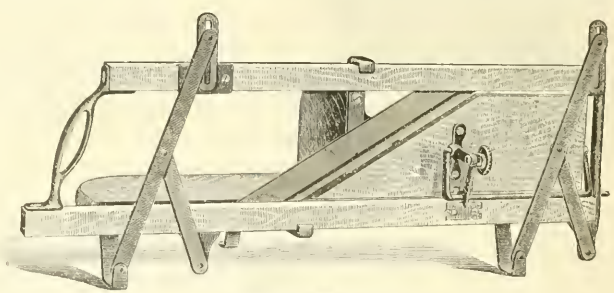
center truss has a base by which it is rigidly fastened to the base of the scale, and to the upper and lower bands of this truss the scale beams are attached, the beam being pivoted at the base, below the lower steel band. Upon these bands the scale tips or oscillates, and the bands take the place of knife edges. The end trusses, one of which is seen in Fig. 2, are only used for holding the ends of the beams in place, and are not attached to the base of the scale. The ends of the beams are fastened to these bands in the same manner as at the center. It is stated that the scales are made of the best material obtainable by experienced and skilled workmen. All parts are interchangeable, and can be easily duplicated if accidentally broken; also, that the working parts

Fig. 2.—Truss and Band.

of the scale are virtually one piece, as the beams are made fast to the fulcrums. It is explained that this obviates the errors arising from the scale shifting, and that the various parts of the balance cannot be displaced. The manufacturers claim that the scales are accurate, durable, sensitive and simple in construction. The scale is made in various sizes, with and without the poise and weighing beam.

The Matador Meat Slicer.

The accompanying illustration is of a slicer being put upon the market by the



The Matador Meat Slicer.

Gwinner Mfg. Company, Hamilton, Ohio, for whom Harmon & Dixon, 118 Chambers street, New York, are agents. The knife is attached to a frame, which is carried by parallel motion levers. It is so arranged that the knife can be adjusted to cut the desired thickness, and the gauge is also adjustable to take up the wear of the knife. It is stated that in the construction of the slicer ordinary grooves are dispensed with and parallel levers substituted, and that the easy action of the knife is not affected by shrinking, swelling or warping. It is pointed out that in this machine small fragments of meat do not find lodgment in the grooves and recesses, and become decayed, on account of the substitution in this machine of levers for grooves.

Wire Glass.

C. S. Weber & Co., 415 Broadway, New York, inform us that they have been appointed general agents in New York, New Jersey, Delaware and the New England and South Atlantic States for the American Wire Glass Mfg. Company of Philadelphia. "Wire glass," the new architectural medium, of which an account was given in a former issue, appears to have been received with great favor by architects and builders. George Hayes, a well known authority on fire proof construction, says: "Glass having a woven wire imbedded therein is substantially fire proof. Glass, when attacked by fire, coming in contact with water will fly into small particles, becoming entirely disintegrated, and will leave any opening which it has filled entirely unprotected. But when woven wire is incorporated, as in the substance known as wire glass, the particles will be most effectually held together, and will protect an opening, resisting the spread or communication of fire. This material would be specially useful in the protection of exterior openings, and would avoid the necessity of cumbersome iron shutters, which are more often neglected than used. A skylight, or glazed roof composed of hollow rafters and glazed with wire glass, will hold out against fire as long as any other portion of a building, giving a thorough protection at a point hitherto the weakest feature of a structure. Besides this, a sure prevention of falling glass by ordinary breakage will be acquired."

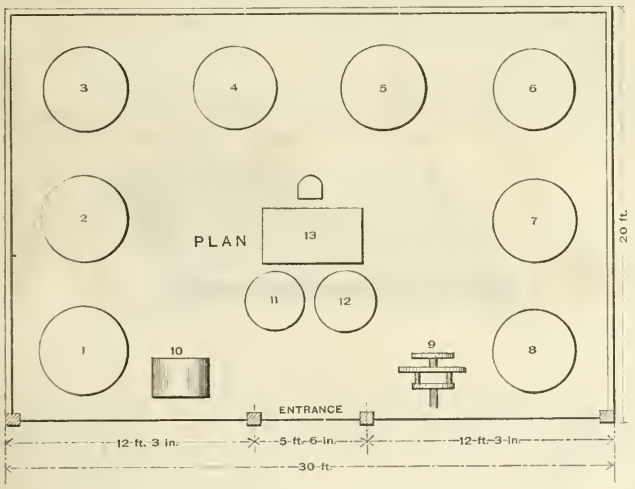
The first invention of wire glass, as now made, was due, as we have before mentioned, to Frank Shumann of Tacony; but the circumstances which led to his invention have not, we believe, been previously noticed. It appears that President Roberts of the Pennsylvania Railroad Company, applied unsuccessfully to the glass manufacturers for a glass stiffened with wire. Mr. Shumann, however, tackled the problem and successfully solved it, and an order for 200,000 square feet of wire glass was placed with his company by the Pennsylvania Railroad Company for their Broad street station at Philadelphia. This one order will give two months' employment to the new manufacturing plant which the American Wire Glass Company have erected at Tocony, near Philadelphia. The works are nearly completed, and will, we understand, be ready for operation soon after May 1. They will run eight pots with a total capacity of 5000 square feet of glass daily.

A new suspension bridge to be erected at Niagara Falls will be a single span of 600 feet and include a double track for the Grand Trunk Railway.

STOVE TRADE NOTES.

The J. F. Pease Furnace Company's Exhibit at the World's Fair.

The space allotted to the J. F. Pease Furnace Company, Syracuse, N. Y., at the Columbian Exposition at Chicago is located in the northeast portion of the building for Manufactures and Liberal Arts on one of the main aisles in Section O, Block 4, and is 20 feet wide and 30 feet on the aisle. The exhibit is classified under Group 116, Class 725. The firm applied for 800 square feet, and the first allotment made by the exposition authorities was a space of 15 x 20 feet, but on the final adjustment this was increased to 20 x 30 feet. The exhibit is mounted on a hardwood platform, and is inclosed on all sides. The aisle front is 30 feet long by 17 feet high, and is constructed of well finished hardwood. The space between the railings is filled with carved panels, and there is also to be a grilling or lattice work under the panel cornice, and from this grilling will be suspended two handsome polished signs with maroon-colored letters. The interior of the booth is finished in hardwood panels decorated in handsome colors, while small incandescent electric lights will be placed at intervals in the cornice at the inside of the booth, and a large arc light will be suspended in the center. Samples are to be arranged as shown in the plan of the exhibit presented herewith. 1 is a No. 120 hot-water heater, cased; 2, a No. 318 Economy low-down water and air combination heater without casing; 3, a No. 314 Tropic furnace, cased; 4, a No. 320 regular pattern warm-air furnace without casing; 5, a No. 314 Economy low-down pattern warm-air furnace without casing; 6, a No. 310 Economy regular pattern steam and air combination heater, cased; 7, a No. 318 Economy low-down pattern steam and air combination heater without casing; 8, a No. 118 New Economy all steam heater, cased; 9, sections of low-down water and air combination heater; 10, steel boiler of a low down steam and air combination heater; 11, bottom, ash pit, fire pot and T grate; 12, bottom, ash pit, fire pot and A. C. grate; 13, flat top desk on which will be arranged a unique little line of nickel-plated models, cut samples of steel, &c. Sections of warm-air furnace and part of their heating apparatus, to show the quality of the wrought steel used, will be displayed in different parts of the exhibit, while upon the walls will be hung pictures of fine buildings heated by Economy heaters.



Plan of the J. F. Pease Furnace Company's Exhibit.

The Excelsior Mfg. Company.

We are indebted to the Excelsior Mfg. Company, St. Louis, Mo., for advance sheets of a catalogue which they are about distributing to the trade. The pages are of large size, and the printing in two colors, red and black, forms a pleasing contrast. The line of goods to which attention is invited is the Charter Oak, provided with wire-gauze oven door. In connection with each stove is presented descriptive matter calling attention to the special features, while tables show the various sizes in which the stoves are made, prices at which they are offered, the code words for ordering the different varieties, together with dimensions of ovens and weights. The Royal Charter Oak is a new line which the company have brought out, with solid oven doors and ornamental base. The general make up of this line is the same as the regular Charter Oak, with the exception of the oven door. The manufacturers state, among other things, that on account of the large number of Charter Oak stoves and ranges which they sell some of the dealers appear to have gained the impression that no other kind is manufactured. The company wish to correct this, and state that they turn out a large line of first-class, medium and low-price cooking and heating stoves; also laundry and tailors' stoves, farmers' boilers and hollow ware. They also sell tinners' stock, as well as tinners' tools and machines. Catalogues of a full line of these goods will, we are informed, be sent to any address on application to the company.

Merritt Peckham.

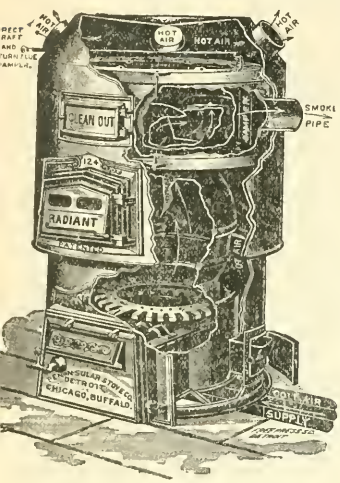
Prominently identified with the stove industry for many years was Merritt Peckham, who died at his home in Utica, N. Y., April 13. He was one of the city's foremost business men, and much sorrow has been caused by his death, though it was not entirely unexpected. Mr. Peckham was born in Pittstown, Rensselaer County, N. Y., onJanuary 20, 1813. He was a son of Seth Peckham and one of a family of 11 children. Mr. Peckham's father acquired the title of "The Plowman of Pittstown," on account of being a manufacturer of plows. The Peckham family were among the pioneers of Rensselaer County. They were Quakers and the deceased had accepted that faith. Merritt Peckham attended the district schools in Pittstown. He spent his spare time in his father's shop, having taken a liking to the business. His father sent him to Troy when but a lad, where he learned the plow-making industry, with Starbuck Brothers, manufacturers of steam engines, plows, &c. He remained in that city about nine years and in 1834 went back to Utica. From that time he resided in that city until his death. John S. Peckham in 1828, succeeded to the plow factory of his uncle, Seth Peckham, at Utica, and in 1835, Merritt Peckham, his half-brother, was admitted to the firm, which was J. S. & M. Peckham. The partnership continued until the death of the senior member, May 2, 1879. The plant of the firm was then located on Catharine street.

In 1840 the firm began the manufacture of stoves, the foundry being located in the rear of the store, 22 and 24 Catharine street. The business grew rapidly and the firm built up a large patronage. Afterward the manufacture of heaters and furnaces was commenced. It was found that larger accommodations were needed, and the firm removed their foundry to the corner of Third and Broad streets, where it is now located. Until the death of John S. Peckham, in 1879, the firm of J. S. & M. Peckham continued. At that time S. Townsend Peckham was admitted, the firm name remaining the same. About a year since S. Townsend Peckham went West, and in February last the firm was changed to J. S. & M. Peckham Company, with the deceased as its president, Merritt Peckham retaining a controlling interest. Although he practically retired from active business life six or seven years ago, he still gave the firm the benefit of valuable advice and wisdom gained by long experience. Mr. Peckham was married about 54 years ago at Trenton, N. Y., to Miss Adeli M. Ross, and six out of ten children survive him. He was an Odd Fellow, an exempt fireman, and held positions of trust on the boards of the Utica Orphan Asylum and

the Faxton Hospital. He never held political office. He was a man of generous traits and held in high esteem by all.

Radiant Peninsular Furnace.

The Peninsular Stove Company of Detroit, Mich., have just brought out a new furnace which is said to be something of a departure in this line of heating apparatus. The construction is known as the Radiant Peninsular furnace, and is adapted for using hard coal, soft coal, coke or natural gas. The broken view presented herewith shows the internal arrangement. One of the features to which the makers direct special attention is the return flue radiator, in which the heat is made to fully encircle the radiator before it passes into the smoke pipe. In addition to this the radiator is supplied with a damper by means of which the smoke or the draft is made to pass directly into the smoke pipe, thus insuring a quick start for the fire, and do-



Radiant Peninsular Furnace.

ing away with any liability of the smoke escaping into the room. Another feature of the furnace is the company's patent duplex grate and annular shaking ring, which is claimed to prevent the accumulation of clinkers, while thoroughly cleansing the fire pot of all dead matter. As it is self-mounting it requires an exceedingly short space of time to pull out the entire grate through the ash-pit door, while it can be replaced in the same time by the most inexperienced. The furnace is also provided with a double extra heavy fire-pot, large ash-pit and other features, which, the manufacturers claim, make it the best article of the kind yet put on the market. The doors and frames of the heater are neatly japanned and highly ornamented in bronze.

Burton Electric Heaters.

A new electric stove, suitable for heating stores, offices and residences, made under the Burton Electric Company's patent, and placed on the market by Taylor, Goodhue & Ames, Monadnock Building, Chicago, is herewith illustrated (Fig. 1). This stove is 36 inches in hight, resting on a handsome nickel-plated base, with a nickel-plated top. The radiating surface is broken up into numerous small projections, with the result, it is claimed, of making it a rapid heater, and, as compared with other similar devices, an economical consumer of current. The connections are made underneath the stove. This heater is provided with a switch, by which the degree of heat may be regulated. Moderate heating will consume from 5 to 7 amperes of current on a 110 volt circuit, while in cold weather the heater will consume from

Burton Electric Heater.—Fig. 1.—General View of Stove.

15 to 20 amperes. At the latter point the stove generates heat very rapidly and water may be boiled within a few minutes. Underneath the nickel-plated top is a flat surface upon which anything may be placed for warming or boiling. The stove itself is a hollow cylinder, and, as the castings are of thin metal, it takes but a short time to heat. Fig. 2 illustrates the new electrical device, made under the same patents as the electric stove, for cooking griddle cakes, and is used to advantage in residences or restaurants where heat and smoke are objectionable. This griddle cake device is about 20 inches long by 15 inches broad, and six griddle cakes can be cooked at one time upon it. It stands about 2½ inches high, and is attached to the socket by a simple plug and No. 18 incandescent lamp cord.

Fig. 2.—Electrically Heated Griddle.

ODD PLATES.

In our issue for last week we presented the text of a decree recently issued in the case of John E. Gaitly against Frederick W. Collins. In order that the trade may not go astray in the matter, we would remark that the defendant in the case was not Frederick W. Collins of the Howe Ventilating Stove Company of Cortland, N. Y.

William H. Switzer, general manager of the Superior Furnace Company, Little Falls, N. Y., has just returned from a business trip, as far West as the Rocky Mountains. He reports trade good in the West and brings favorable accounts from the Missouri River towns. Mr. Switzer booked some large orders for the Superior Furnace and informs us that the new Superior steel range was received with much favor by the Western trade.

An interesting record that conveys or suggests an idea, which may awaken useful reflections, has been kept by Kedian Bros. of 248 Third avenue, New York. Since 1866 they have a yearly record of all of the heating stoves they have sold, and it shows a steady and gradual decline for a number of years back, while their general business has increased. A possible explanation is that in an old and thickly settled section the demand is satisfied or is supplied with the gas and oil heating stoves, which have in the same period increased in use.

The Excelsior Hardware Company at 58 Warren street, New York, represent John Wright of England, the manufacturer of gas stoves and open fires. They also handle the line of gas stoves and gas cooking goods of F. & L. Kahn of Hamilton, Ohio. In addition to these goods they are making a line of one, two and three burner hot plates after designs of their own. The increasing demand by the people of all classes for gas goods is made very apparent to them, owing to the varied line they carry, and their shipments increase accordingly.

L. A. Buck, representing the Ringen Stove Company, St. Louis, in the interest of their quick meal gas and gasoline stoves, has made a remarkable record during his last trip. He visited 295 towns, and entered 288 orders. To indicate the success of his trip, it might be remarked that the Ringen Stove Company sell to one dealer only in each town.

The new plant of the Joseph Bell Stove & Range Company at Muncie, Ind., is now ready for the machinery. The Lake Erie road is rushing to completion a switch to connect with the stove works. This will be ready in a few days and then the machinery will be placed. The machinery used has been brought from the old works at Wheeling, W. Va., and is now on the ground. It is expected that molding will begin within a few weeks. The new buildings are models of completeness and adaptability and are admirably located. The Bell Company own a tract of seven acres on the bank of the White River and in this tract they have their own gas well. They will have about three times the capacity in the new works that they had in the old. They desire the trade to know that while they have abandoned the manufacture of stoves and ranges at Wheeling, they will maintain there a large warehouse filled with complete lines of their well-known goods, and that the Eastern trade will be supplied as promptly as before.

The Simonds Mfg. Company, at 50 Cliff street, New York, make a rack that can be attached to any wall register, and which serves as a foot rest, or is an excellent place to set a glass dish to hold water for contributing that moisture to the atmosphere which many persons consider necessary for comfort.

A notice conspicuously displayed informs the trade that the Marcy Stove Repair Company will occupy larger and more convenient quarters at 74 Beekman street, New York, about May 1.

We have received with the compliments of the Laura Nevins Range & Heater Company, St. Paul, Minn., a pamphlet of 16 pages, of a size convenient to carry in the pocket, and relating to the

Laura Nevins Range. Within the covers of this little book is to be found a full description of the stove named, as well as a large number of testimonials from those who have used it. The stove is illustrated by engravings showing a general view, and also sectional cuts indicating the interior construction.

THE TROY OIL STOVE COMPANY of Troy, N. Y., are distributing circulars relating to their New Beauty oil stove, which is offered the trade in a variety of sizes and styles. It is made of cast iron, from new patterns, and is placed upon the market as representing original ideas. Every burner is supplied from the bottom with air, coming up through the oil tank, which tends to keep the oil cool. There is also supplied in connection with each burner a spreader, which gives a clear, large flame. The ornamentation of the New Beauty is neat and effective, and it is meeting with a gratifying demand.

THE THATCHER FURNACE COMPANY, 33 Peck Slip, New York, report the receipt of large orders through their traveling salesmen who have been visiting the trade in the West. On account of new improvements which have been made in the company's mounting and molding rooms, they are now in a position to promptly handle all orders, great or small, with which they may be intrusted. Mr. Benedict, the vice-president, is also superintendent of the foundry, and, being a practical furnaceman, everything runs along very smoothly and satisfactorily.

THE PENINSULAR STOVE COMPANY of Detroit, Mich , have forwarded to Chicago material for their exhibit at the World's Fair. It consists of 23 stoves and ranges and one furnace, the goods being highly finished and embodying all the modern improvements. One of the most interesting features of the exhibit is the display of wrought-steel ranges intended for use in hotels, restaurants and other places where a large amount of cooking is required. One of the ordinary cooking ranges in the company's exhibit has been nickel plated throughout and finished with a high polish. The company expect that their exhibit will be one of the best at the World's Fair, as they have spared no time and trouble to make it first class in every respect. The company will occupy a space 20 x 35 feet in size in the building devoted to manufactures. The stoves will stand on an old gold carpet in front of a red plush background.

THE FULLER & WARREN COMPANY, Troy, N. Y., send us a pamphlet of 12 pages, which is known as their range supplement No. 3. It is neatly printed in two colors, and describes three new ranges which the company have brought out. These are known as the F. & W. Co.'s No. 38, provided with oval fire box, triangular grate, large portable wrought-steel oven, heavy linings, large cut top and other features of convenience and utility; the Advance, a six-hole range of neat appearance and embodying the modern features; the New Rescue, a five-hole range, made for burning hard and soft coal or wood, and the New Advance, another member of this general class. One of the features of the pamphlet is an illustrated description of the direct draft damper as arranged for the No. 38 wrought-steel oven range. This damper is placed on the back of the stove and out of the way of anything that may be on the top. The words "open" and "shut" are cast on the top, thus making it impossible for any one to become confused and turn the handle the wrong way.

SECRETARY EDWARD BOWDITCH of Rathbone, Sard & Co. has returned from a visit to the South, where his family have been for some time.

THE OHIO STOVE COMPANY of Portsmouth, Ohio, have just completed the erection of a large and substantial brick structure adjoining their present plant. It will be used for offices and warehouse purposes, while the old building will be used entirely as a foundry. A number of new patterns of cook stoves and heaters have been added to the company's already extensive line, among the number being the Buckeye range, the Columbia square heater, and a new parlor cook stove. The works of the company are running full in all departments in anticipation of a large fall trade.

THE IMMENSE sample floor of the Albany plant of Rathbone, Sard & Co. has been redressed in regal fashion. The ceilings and side walls have been handsomely frescoed in harmonizing tints and striped in gilt. The radiators and iron work have also been handsomely gilded. The Lamson cash-carrying system has been put in between the office and the repairs and shipping departments. This has been found to be a most useful facility. The sample floor is being rearranged and will show all of the immense lines of stoves and ranges manufactured by the company.

THE EXCELSIOR STEEL FURNACE COMPANY, Chicago, Ill., appreciate very thoroughly the advantage of the free use of blanks in keeping records and obtaining information. Two interesting samples of such publications of theirs are blank for individual report and town report, to be filled out by their traveling salesmen. The individual report, a sheet of ruled paper 10 x 8 inches in size, is arranged at the top for inserting the name of the firm, location, date, capital, salesman reporting, principal stock carried, appearance of the store, trade papers taken, if advertisement has been seen, and, if so, where, with two lines left for comments, while below are 28 lines for the names of creditors, the amount, time and report. On the back of the sheet are squares for memoranda of the goods handled and from whom bought, these including a line of heating apparatus and appliances. The second form is for a town report, giving name, State, the fuel chiefly used, system preferred, whether hot air, steam or hot water, estimated sale of furnaces and other heaters, leading furnace dealer, while blanks are left for the names of the different dealers in hot-air furnaces, steam boilers and hot-water heaters, together with a column for the insertion of the name of furnace or boiler sold. On the back of the town report is memorandum for quotations made on furnaces, fittings, &c. Altogether the forms are got up in the most complete way, and if properly filled out must bring to the Excelsior Steel Furnace Company a vast fund of most valuable information.

SUPERINTENDENT LIDDLE of the Perry Stove Company of Albany, N. Y., says that, notwithstanding a backward spring, it has opened favorably for the company, he having no fault to find with the demand up to date. The company are preparing some new goods which they will probably offer to the trade in the near future. The trade in oil goods has opened briskly and promises well. The company expect to run their plant full during the summer.

A HANDSOME new sign has just been got out by Rathbone, Sard & Co., Albany. It reads: "Acorn Stoves and Ranges," in fancy black letters on an aluminum background. It is to be hung in windows.

THE EXCELSIOR MFG. COMPANY, St. Louis, Mo., have just issued from the press an eight-page circular relating to Filley's Challenge steel ranges, which are shown in several varieties. The Challenge range is made of cold-rolled steel with steel angle corners, closely hand riveted and every rivet countersunk. Where bolts are employed the steel plate is threaded to receive the bolts, thus making, the company state, "the strongest, handsomest, heaviest, finest finished and most perfectly constructed steel ranges manufactured, embracing every improvement of merit." Both ends of the range are lined with heavy asbestos, while the top flue above the oven, or over the over door, has cast-iron lining, which will prevent the heat from burning off the paint. The appearance of Filley's Challenge range is very neat, and the company confidently expect for it a large demand. The circular also calls attention to the Monarch steel range, the closets of which have a door which rolls back out of sight and out of the way, thus leaving an opening the entire length of the closet. Other features of convenience and utility are embodied in this range, which is made in a variety of styles.

H. H. WATERMAN of New York City, representing the Central Oilgas Stove Company, has just returned from a four months' trip through the Southern States. He reports having booked a number of good orders, and taken as a whole the sales are said to have been double what they were for the corresponding period of last year. Mr. Waterman has a certain magnetism which has led to the remark that "his friends stick to him like sealing wax."

WE ARE INDEBTED to the Chicago office of the Detroit Stove Works, Detroit, Mich., for a proof of the first page of the World's Fair edition of *The Jewel Record* which will be distributed to the trade next week. The page presents the particulars of an interesting and unique programme of a special feature of World's Fair entertainment. The company announce to all their customers and stove merchants throughout the country that arrangements have been completed for running a line of "Jewel" Tally-ho coaches during the World's Fair regularly from the Chicago headquarters of the company, 269–271 South Canal street, to the World's Fair grounds and return. The exact route the coaches will take has not yet been definitely decided upon, but we understand it will include a ride of at least seven miles each way, over the boulevard system of Chicago. Accompanying each invitation sent out by the company will be a pass admitting the holder to a seat on the coach. The only condition which the company impose upon their friends is their registration and counter-signature of the pass at the Chicago office. Owing to the small amount of space which it was possible for the World's Fair authorities to allot to each exhibitor, and also to the fact that the time for the preparation of an exhibit was very limited, the company state that their World's Fair display of Jewel stoves will be shown at their Chicago headquarters. In this connection it may be interesting to state that merchants intending to accept the company's invitation should communicate with the Chicago headquarters at least ten days in advance of their arrival and give the date when they desire to ride on the coach.

THE STUART & PETERSON COMPANY'S new hollow-ware plant at Burlington, N. J., covers ground 410 x 200 feet, and the foundry building is 280 x 67 feet, the main building being three stories. The fire protection is excellent, there being automatic sprinklers on every floor. The enameling ovens are of improved patterns and are capable of the enameling of extra large articles. There are many improved appliances in connection with the plant, mainly the result of extended investigations by a member of the company during a special visit to Europe. The Kearns improved japaning ovens are used, the

only ovens of the kind in this country. The turning lathes turn out the ware automatically, and it is claimed that their set of lathes are, of the kind, the only in existence. There are excellent wharfage facilities at the works, large vessels being enabled to receive and discharge at the company's own wharf. There is a railroad switch opening directly into the plant. Operations were commenced April 1.

In a page announcement Rathbone, Sard & Co., Albany, N. Y., direct attention to their Acorn specialties, and present an illustration of the Magnet Acorn range, intended for hard coal, soft coal or wood. A general account is given of this range, and its special features are alluded to.

The Kansas City Stove Works, Kansas City, Mo., in an announcement in another part of this issue this week direct attention to the Champion Stoves and Ranges of their manufacture, the several excellent features of which are referred to in the text, while an illustration is likewise presented.

The Ringen Stove Company, St. Louis, Mo., have just shipped what is undoubtedly the largest single car of stoves ever sent over any road in this country. This car was specially contracted for and is a veritable warehouse on wheels. It is the property of a private individual and was rented by the Ringen Stove Company for this purpose. It contained 300 stoves, mostly large sizes. The dimensions of the car are 52 feet in length, 10 feet wide and 11 feet in hight.

S. H. Plumb, traveling for the Stamford Foundry Company, Stamford, Conn., is one of the steady men of the trade who is doing good work in New England for his concern.

The Fuller & Warren Company, Troy, N. Y., have got up an advertising novelty in the shape of a metal sign, measuring about 14 x 6½ inches in size, and supplied with a short piece of brass chain, by which it may be suspended in a conspicuous place in the dealer's store. The upper left-hand portion of the sign, which is made of brass, bears the letters "F. & W. Co." At the right of this and occupying the principal portion of the space is the inscription in black letters, "P. P. Stewart Stoves." The company are also distributing some paper signs of about the same dimensions as the metal one, carrying embossed japanned inscriptions, printed in various colors, relating to the company's lines of stoves, furnaces and ranges.

The Smith & Anthony Stove Company of Boston, Mass., are in receipt of a number of letters which they state have been brought out by their recent announcements in the columns of *The Metal Worker* relating to their Hub Heater Furnace. As they put it, "The question of priority seems to have raised a great deal of interest among the trade."

Applications of Coal Gas for Heating Purposes.

The following article, which deals with a subject in which many of our readers are more or less interested, appears from the pen of Thomas Fletcher of Warrington, England, in a recent issue of the *Gas World*:

I have repeatedly had to deal with the problem of heating large beer-bottling stores for conditioning bottled beers; and the experience obtained is valuable for other purposes. No bottled beer would be salable either in this country or abroad unless it is sufficiently charged with carbonic acid gas. The quantity held by the beer in cask is insufficient to produce a satisfactory "head;" and the simplest method of obtaining the required condition is to promote fermentation in the beer after it is bottled and corked: for this a steady temperature of 57° F. is desirable. My earlier attempts have been fairly satisfactory; but the difficulty has been to make the bottlers understand the necessity for carrying out details correctly; and I have never, until recently, been able to obtain an exact and scientifically conducted test which would put the matter on a proper basis. This has at last been done in the bottling stores of Sir Andrew Walker & Sons, Limited.

In my own experience it has been proved repeatedly that for work of this class, where diffused heat, sometimes exceedingly small in amount, is required in large spaces, the best burners are ordinary lighting jets, placed as near the floor as possible, in rows on an ordinary gas pipe, the jets being placed at distances of from 7 to 10 feet apart. With regard to the position of the burners for equal temperatures, the smoke test, verified by a series of exact experiments in plant-house heating, proves conclusively that any irregular distribution of the sources of heat causes eddying currents and great irregularities. In one case a difference of 8.5° F. between two points 6 feet apart has been observed.

The position of the burners indicated by these experiments is one or more straight lines, which, by causing an upward current, induce a corresponding descending one at the part of the room furthest away from the burners. The rooms where the tests were made are three in number—all adjoining each other—the sizes being:

Feet long.	Feet wide.	Feet high.
91	23	8
20	19	8
22	20	8

The total wall surface is 3000 square feet, and the window surface approximately 100 square feet. In the largest room seven brewers' standard thermometers were used.

Owing to the arrangement of the contents, it was found most convenient to run two 1-inch iron pipes on the floor near the center from end to end, with the necessary breaks for cross traffic. In these are screwed, at every 8 feet, one No. 2 Bray's union jet burner, and each pipe is controlled by a 1-inch gas tap, with lever arm and quadrant for exact adjustment. The thermometers were placed:

A, 5 feet 6 inches from floor, 6 feet from nearest burner.
B, 3 feet 8 inches from floor, 6 feet from nearest burner.
C, 7 inches from floor, 6 feet from nearest burner.
No. 1, near door, 11 feet from nearest burner.
No. 2, center of room, 1½ feet from nearest burner.
No. 3, center of room, 7 feet from nearest burner.
No. 4, end of room, 11 feet from nearest burner and 7 feet 6 inches from No. 1.

All adjustments of the gas were made by hand on an ungoverned service, and the following gives a week's readings:

3	55½	58	58
4	55	58	8
Outside	45	46	42

Thermometers A, B, and C, vertically over each other, were respectively 7 inches, 3 feet 8 inches, and 5 feet 6 inches from floor, in a room 8 feet high. In 6 out of 16 readings the difference between the three did not exceed 1° F. The greatest difference was 3° F.; and occurred in only one reading. So that, for all practical purposes, the heating of the room vertically may be considered perfect. The most striking point is the extreme uniformity of heat obtained by hand regulation during excessive changes outside. The total gas consumption for heating the three rooms was taken twice. With an outside temperature of 19° F., the consumption of gas was 100 cubic feet per hour; with an outside temperature of 35° F., the average was 50 cubic feet per hour.

In the two smaller rooms a center tube was impossible; and the only available method was to put a pipe with union jets along one wall, near the wall and near the floor. One end of the pipe was turned to run along the next wall for about 6 feet. This, I think, is a mistake; and further trials will be made without this extra length. A break in the straight line of jets evidently causes eddying and irregular currents. As a proof of this, the reading of the thermometer 2 feet 6 inches from the end flame was 56° F. in the center of the room, and 10 feet from the nearest flame 58° F.

Taking the whole result, I found that, with a wall surface of 3000 square feet and windows 100 square feet, a gas consumption of 100 cubic feet per hour will maintain a rise of 39° F., which will give approximately the following rough rule: 1 cubic foot of gas burned per hour will maintain a rise of 1° F. in a room having 1200 square feet of wall surface, if burned in a common lighting burner near the floor, with very limited ventilation and good brick walls. My method of calculating by the wall surface is, I believe, the only one which is of any value in this class of work, as practically the whole of the loss is through the walls. The amount expended on heating the air is exceedingly small in any case where the ventilation is limited; and it must be very clearly borne in mind that the gas consumption given is only the amount necessary to maintain the temperature after the correct heat has been obtained by steady heating day and night, until the inner wall surface corresponds in temperature with the air in the room.

As a maker of atmospheric burners, this would appear to be a matter outside my own special department; but it is one of very considerate interest to gas engineers, and therefore, if not directly advantageous to myself, is worthy of careful consideration, as showing the simplicity, perfection, and cost of exact work on a fairly large commercial scale. There is no doubt whatever that the steady temperatures obtained would be impossible with any system of steam or fire stove heating, and would be very difficult, even if possible, by hot-water pipes. If steam were used the heating of the pipes would be very irregular, unless working at full power; and the accumulated heat in hot-water pipes would prevent the rapid adjustment required for the great outside variations which constantly occur.

Halifax is at loggerheads with the Dominion Government on the question of admitting emigrants to land without fumigation at quarantine.

TRADE REPORT.

The Iron Market.

The course of the market during the past week may be summed up in a very few words: "Iron firmer, Steel weak and a shade lower." The general situation, however, is practically unchanged, and so far as any one can see is not likely to change to any very important extent. The most notable feature is the steady absorption of stocks of Pig Iron, and the possibility of an unexpected advance in case there is no change in the proportions between supply and demand. At present it is perfectly clear that we are using more Pig Iron than we are making, which of course cannot continue much longer without affecting prices. On the other hand, Steel shows signs of weakening, which may in some measure offset the strength in Iron. However, a good deal will depend on developments during the next 30 days, so that it is impossible for any one to say for certain what course the market will take. It will not require any very great amount of new business to make things very active. There is enough on hand to give a splendid backing, all that is required is to take deliveries on lots already sold. The Ore situation is still in abeyance, but the impression is that prices will not change to any very important extent. There is some talk of an attempt to advance freights on Soft Coal, and on Ores, but the thing is so absurd and so unreasonable that it is hardly likely that it will amount to anything. Eastern mills and furnaces are already so badly handicapped that any further steps to increase cost could only result in a wholesale shutting down and blowing out. Taking everything into account, we should be inclined to say a little higher prices are not unlikely for Foundry and Mill Irons; perhaps a little lower for Steel stock, but with prompt specifications for the Finished Material contracted for during January and February, we may see better prices for Plates, Shapes, &c., which at present are at the lowest on record. Mills rolling Iron and Steel Bars are only moderately active, and extremely low prices continue to be named for desirable orders and specifications. The makers of Pipes and Tubes met in New York City last week and rearranged prices and discounts. Wire continues active with prices being firmly maintained. More or less anxiety will be felt in business circles from this time forward over the settlement of the wage scales. Interviews with prominent manufacturers in different branches of the trade indicate that if the workmen exhibit a spirit of fairness when the time comes to take up the different scales in conference, there will not be any difficulty in bringing about settlements that will be satisfactory to all concerned.

Pig Iron.—In the New York market makers of standard Northern brands report a very good run of business, while agents of some of the other furnace interests, North, and South, report that current business is confined practically to carload orders. Reports of cutting are again heard, the most conspicuous case being the offering of No. 2 Southern Iron by a prominent maker to consumers direct at $9, Birmingham. We quote Northern brands at $14.50 @ $15.25 for No. 1; $13.75 @ $14.50 for No. 2, tidewater. Southern Iron, same delivery, $14.25 @ $14.50 for No. 1; $13 @ $13.50 for No. 2 and $13.25 @ $14 for No. 1 Soft.

Both Foundry and Mill Irons appear to be in a good position in the Philadelphia market; and while there is no quotable change in prices, they are distinctly firmer, and with a continuance of present conditions will probably soon work to a higher level. All the best known brands are close sold up; some, indeed, are engaged up to the fall months, so that it is a matter of favor more than business to be able to place an order at current quotations. Medium brands are also pretty well cleaned up, while the very low qualities have also been liberally taken, but at extremely low figures. One lot of about 10,000 tons is said to have been secured at a very small fraction over $12, Philadelphia, but the cleaning-up process has been so thorough that there is now really very little Iron of any kind to be had at less than quoted rates. The situation is in fact a very comfortable one for sellers, inasmuch as they are not heavily loaded with stocks, while there is a demand at prices which can be pretty accurately calculated upon. At the same time, there is nothing specially urgent in the demand, neither are consumers in the least alarmed at the possibility of a scarcity. The capacity for production is so large that every 25¢ advance in prices will add to the supply, while a dollar might again lead to an undesirable surplus. Under these circumstances, the situation attracts no unusual attention, and, barring the possibility of slightly higher prices for the better grades of Foundry and Mill Irons, there is nothing to indicate any decided change from the figures recently ruling, which in ordinary cases are quoted as follows for Philadelphia and equivalent deliveries, with 25¢ @ 50¢ less on Southern brands at Harrisburg and Intermediately to Baltimore:

American Scotch, No. 1X	$16.00	@	$16.50
American Scotch, No. 2X	15.00	@	15.50

From Chicago we learn that the demand is of an irregular character, covering heavy transactions of special qualities, with only light sales in a general way. Among the contracts placed the past week was one for several thousand tons of Bessemer Pig. Local manufacturers are still enjoying the bulk of the business. Their prices are quite firm but unchanged. Representatives of Southern companies are talking a little more cheerfully, having advices that on most grades their companies are now well sold up. Less is heard of concessions on Southern, cuts of 5¢ @ 10¢ securing such orders as are now current. Inquiries are a little better for Lake Superior Charcoal. Consumers talk about purchasing considerable quantities, but it is likely that, as usual, they will discuss the matter for some time before really entering the market. An effort is being made to push Charcoal prices down, and reports are current of weakness in some quarters, which the manufacturers deny, claiming that the small sales now being made are realizing $16.75 and higher. Quotations are as follows, cash, f.o.b. Chicago:

Lake Superior Charcoal	$16.50	@	$17.00
Local Coke Foundry, No. 1	13.75	@	14.25
Local Coke Foundry, No. 2	13.00	@	13.25
Local Coke Foundry, No. 3	12.75	@	13.00
Local Scotch	14.00	@	15.00

In Southern markets there has been a slow and easy Pig Iron market during the week, the demand being mainly restricted to the current consumptive necessities of consumers, who as a rule are indisposed to anticipate their wants, and while some of the stronger Southern Iron companies are not disposed to accept orders for long forward delivery at current prices, yet orders can be placed for delivery all this year for No. 2 Foundry at $9 and for Gray Forge at $8, f.o.b. Birmingham. There is a fair inquiry for Mottled Neutral Coke Iron, and, being in light supply, it sells pretty close up to Gray Forge. The reduction in stocks during the month of March does not seem to have any influence upon the market, probably because the capacity of the furnaces in blast or available for production is large enough to meet all probable demand. There is no demand for Charcoal Iron except in a retail way, and even that is scarcely of the usual proportions. Quotations are as follows:

Foundry.

Southern Coke, No. 1	$13.25	@	$13.50
Southern Coke, No. 2	11.75	@	12.00
Southern Coke, No. 3	11.00	@	11.25
Ohio Soft Stone Coal, No. 1	16.00	@	16.25
Ohio Soft Stone Coal, No. 2	15.00	@	15.25
Mahoning and Shenango Valley	14.75	@	15.00
Hanging Rock Charcoal, No. 1	19.00	@	19.25
Hanging Rock Charcoal, No. 2	18.00	@	18.50
Tennessee and Alabama Charcoal, No. 1	15.50	@	15.75
Tennessee and Alabama Charcoal, No. 2	14.50	@	14.75

Metal Market.

Copper.—Some contracts have been made for Lake Superior Ingot for future delivery. As to the quantity of Metal involved and the prices paid, secrecy is observed. In this particular the large producers are as non-committal as they are regarding the amount of Copper on hand, and through this perverseness encourage suspicion regarding what little information does come to the surface regarding the true status of the market, besides developing suspicion as to accuracy of statistics of production. In short, there is strong circumstantial evidence of manipulation in more directions than one, not the least among which is the dissemination of misleading reports as to true market value. For example, the word is dropped that the leading producers are not sellers at less than 11¼¢. That and higher prices were quoted some time ago, but there is reason to believe that good-sized orders have been taken recently at 11¼¢ if not at a lower price, or at concessions from "nominal" prices that have been the rule for several months in certain quarters. In support of this is the fact that "outside" lots have gone a begging at 11¼¢ and that distant future deliveries were offered on the Metal Exchange at as low as 11.15¢ without stimulating inside or outside speculation to the slightest extent. Upon the whole it would appear that the restriction of output has thus far had little effect outside of preventing prices from falling to a normal point. Casting Copper is generally quoted at 10½¢, but desirable orders at ⅛¢ less would probably be clinched, and it is not certain that bids of 10¼¢ for large blocks would be refused. Some Lake Ingot has been sold for export at 11¼¢, and it is understood that negotiations involving 5000 tons are under way.

The monthly production of Copper in the United States since July has been as follows, the first column giving the aggregate returns from the reporting mines, which include the principal lake, Montana and Arizona producers; the second being the metal from pyrites and from a number of smaller outside sources, being estimated:

American Product.

1892.	Reporting mines. Gross tons.	Outside sources. Gross tons.	Total. Gross tons.
July	9,294	924	10,218
August	10,807	870	11,677
September.	9,710	994	10,704
October	9,668	1,289	10,957
November.	9,888	1,036	10,924
December.	9,872	1,174	11,046
Total, six months.	59,239	6,287	65,526
1893.			
January	9,187	989	10,176
February.	8,213	1,042	9,245
March	9,065	1,321	10,386

The product of the foreign reporting mines was as follows:

Foreign Reporting Mines.

1892.	Gross tons.
July	6,358
August	6,888
September	6,478
October	6,476
November	6,789
December	7,666
Total six months	30,655
1893.	
January	5,736
February	6,702
March	6,896

The exports of fine Copper from the United States were as follows:

United States Exports.

1892.	Gross tons
July	3,450
August	1,545
September	1,458
October	3,144
November	3,897
December	4,486
Total six months	17,980
1893.	
January	3,171
February	1,815
March	2,334

Pig Tin.—The "bull" interest in the speculative arena have had a new card in the shape of advices by wire of shipments of only 775 tons from the Straits during the first half of April. They also had some assistance from London in the form of stiff quotations there for prompt and near future deliveries. Neither circumstance has, however, counted for much against the natural weight of excessive supplies on this side of the Atlantic and strong circumstantial evidence that no opportunity is missed in this or the foreign markets to transfer holdings At present, London is selling futures at a heavy discount, while a considerable premium is still maintained by the local manipulators. The natural deduction from this is that the United States is destined to be the dumping ground for a large amount of Tin attracted from the primary sources of supply by the McKinley tariff law. Trade demand is running slower at present than it has for some little time past, chiefly for the reason that jobbers are quite liberally stocked, and purchases for consumption are on a more restricted scale also, although very fair in the aggregate amount. At the close of the week prices softened to 20.65¢ @ 20.70¢, net cash, for 10-ton and larger lots, and buying interest was very tame.

Pig Lead.—The higher prices established on last week's transactions have been maintained, but buyers have become more cautious and the volume of business for the period under review makes a very indifferent showing. Spot offerings are moderate, however, as are also round lots for near future shipment from the West and at less than 4.17½¢ there is little Lead on sale. The popular quotation at this writing is 4 15¢ bid, 4.20¢ asked.

Spelter.—Sales have been made of carload lots at 4.40¢ delivered here and at other Eastern points. At this writing 4½¢ is generally asked and the indications are that no considerable quantity of the metal can be secured at the intermediate price. The rise is due chiefly to steady consumption that is now quite on a level with the production and apparently ahead of late calculations. Efforts to effect a combination of producers have been renewed, but thus far it does not appear that the market has been affected thereby.

Antimony.—Outside of routine jobbing sales there has been little doing, and the demand at present is slow. Prices remain quite steady, however, at 10½¢ for Hallett's, 10⅝¢ @ 10½¢ for L.X. and 10⅝¢ @ 10¾¢ for Cookson's.

Tin Plate.—Coke Tins, of 100 lb and lighter weight, have realized very good prices, unsold supplies of the same being under close control at the moment. Other varieties have merely held their own, however, since supply and general assortment is now somewhat fuller. Still the change in prices is narrow, and without sign of the supply becoming at all burdensome. The demand for Tin Plates from consumers continues moderate, with no change in prices.

Coal.

Anthracite Coal is dull and easy, except Buckwheat and Pea, which are scarce, the former at $1.85 @ $2, f.o.b.; Pea, $2.50 @ $2.65, f.o.b. Stove and Chestnut are $4.15 alongside, which is the net circular. The accession of Mr. Harris in the Reading management as yet has no effect on the trade. Large sales of Egg, Stove and Chestnut are reported at prices 25¢ under the circular. Bituminous Coal is quoted $3 25, and prices are said to be well maintained. Western Coal prices will be considered April 25, and a meeting of freight agents to adjust railroad tolls to Western points will soon be held. The Bituminous operators report no later contracts.

The total Anthracite Coal production since January 1 is 10,814,000 tons, an increase of 887,000 tons compared with last year. The Reading Company is operating 51 collieries three-quarters time, and, having already a large tonnage piled up at tidewater, have begun to stock coal in the storage pockets near Mahanoy. The bituminous mines are active. Clearfield production for the week, 67,451 tons; Huntington, 45,735 tons; Norfolk and Western, 70,136. All regions are ahead of last year.

Financial.

The condition of the United States Treasury is again the uppermost theme, the loss of gold by the outgoing European steamers having raised the question whether the parity of the two metals, gold and silver, can be maintained much longer. At the present time silver is a fraction below 38 pence in the London market. It is generally believed by Treasury officials that the order stopping the issue of gold certificates which was given last Saturday, and the expected gain in the condition of the gold balance, will preclude the necessity of an issuance of bonds. The majority of the bank officials in this city believe that the order referred to will have no direct effect on the situation. One bank president said: "The whole thing resolves itself into a formal announcement that the Government treasuries can no longer be used as a warehouse for gold coin. The step now taken should have been taken years ago; in fact, should have been arranged for simultaneously with the resumption of specie payments in 1879." Another bank president said: "The Secretary, in making the order, simply obeys the law. It was formerly designed to make speculation in gold impracticable by compelling traders to make deliveries in actual coin. This condition no longer pre-

vails, and it is possible the step is simply the first movement in the direction of bond sales. A large amount of bonds are already printed and ready for delivery to agents of prominent European banking houses, who will ship gold to pay for them from the other side as soon as the issue is announced here." The continued export of gold to supply the Austrian demand, together with the probability that gold will go out for some time to come, causes an uncertainty of feeling detrimental to all interests, especially as the excess of foreign imports at New York is the largest ever known. At the same time the exports of breadstuffs, cotton, provisions, cattle and oil in March were $17,889,184 less than in the same month last year. On the other hand, low prices for cotton should stimulate exports of that staple, and enormous amounts of grain will come forward on the opening of navigation. The recent Australian failures, which in the aggregate are comparable to the Barings failure, tend to increase the stringency in Europe, and are an unfortunate coincidence as related to monetary affairs in the United States.

Returns of the foreign commerce of the entire country for nine months to April 1 are important. During March alone the imports of merchandise were $26,000,000 in excess of the exports, and for nine months, specie excluded, there is an adverse balance of $47,000,000, as compared with a favorable balance of $209,000,000 for the same time in 1892.

The general markets are dull for the reasons above intimated and in the absence of speculation. One exception was coffee, which broke sharply under a bear raid, and business on Monday was larger than before for several years The net decline was equal to $1.50 ℔ bag. Cotton and wheat were also lower. Spot cotton was marked down $\frac{3}{16}$¢. In wheat the most notable feature is the area of the Indian crop, which shows an increase of 2,750,000 acres. Crop accounts from Texas are very good. Corn is up 6 or 8 inches, and oats are occasionally seen in head. West there is nothing in the general outlook for winter wheat to warrant as large a crop as last year's. Provisions are rather firmer. Anthracite coal is weak, while bituminous prices are well maintained.

For the nine months ending March, 1893, the exports of breadstuffs were $145,032,000; for the corresponding nine months in the previous fiscal year they were $233,159,000, a falling off in nine months of $88,127,000. The decrease in the exportation of hog, beef and dairy products has been almost equally marked. For the nine months ending March 31 the exports of these products were $27,300,000; for the corresponding nine months of the previous fiscal year, $33,983,000, a falling off of $6,683,000.

The port of Acre on the Mediterranean, the only good harbor between Alexandria and Beyroot, has been connected with Damascus by an English company and promises to become commercially important.

Chicago Report.

Scrap.—Wrought Scrap is very weak, consumers forcing prices down. Stove Plate is in demand, and dealers are offering higher prices for it. Dealers' buying prices are as follows :

	Per net ton.	Per lb
No. 1 Wrought Scrap	$13.00	....
Machinery Cast	10.00	....
Malleable Cast	7.00	....
Stove Plate (free of burnt)	8.00	....
Burnt Iron and Grate Bars	5.00	....
Sheet Iron and Hoops	4.00	....
Plow Steel and Breaking Stock	8.50	....
No. 2, such as Shovels, Hoes, &c.	4.50	....
Old Boilers—whole (Iron)	8.00	....
" (Iron)—cut in single Sheets and Rings	12.00	....
Old Gas-Pipe and Boiler Tubes	9.00	....
Cast Borings	5.00	....
Turnings	6.00	....
Horseshoes	12.50	....
Copper Bottoms	....	8¢
Copper Clips and Heavy	....	9½¢
Heavy Brass	....	8½¢
Light Brass	....	4 ¢
Pipe Lead	....	3 ¢
Tea Lead	....	2¾¢
Zinc	....	3 ¢
Rubber	....	3 ¢

Anthracite.—A new price list is to go into effect about the 25th. Meanwhile carload lots of 12 net tons are quoted as follows:

	Grate.	Egg, Sto. and Ch.
Chicago, Ill	$5.85	$6.10
Milwaukee, Wis	5.85	6.10
Kansas City, Mo	9.05	9.30
Council Bluffs, Iowa	9.05	9.30
St. Joseph, Mo	9.05	9.30
Leavenworth, Kan	9.05	9.30
Omaha, Neb	9.05	9.30
Burlington, Iowa	7.35	7.60
Des Moines, Iowa	8.80	9.05
Davenport, Iowa	7.15	7.40
Dubuque, Iowa	7.15	7.40
Madison, Wis	7.35	7.60
St. Paul, Minn	8.35	8.60
Lincoln, Neb	9.20	9.45
Sioux City, Iowa	9.05	9.30
Aberdeen, S. Dak	9.10	9.35

Colorado Anthracite.

COLORADO FUEL & IRON COMPANY.	
Denver	$8.00
Pueblo	8.00
Colorado Springs	8.00
Leadville	8.00
Cheyenne, Wyo	10.00
All points between Denver and Missouri River	9.35

Coal Dust Explosions as a Motive Power.—Accounts come from Germany that Krupp, the famous gun maker, is now building a number of experimental engines to test a novel idea. A German inventor has taken patents on the utilization of the general principle that finely divided carbonaceous matter floating in the air readily explodes. He proposes to grind coal to an impalpable powder, and after introducing the dust floating in the air into the cylinder of an engine, explode it, the idea being to follow very much the same lines which are being so thoroughly developed in the use of gas in engine practice. Naturally, the first question which has risen has been how to get rid of the ash. Krupp is reported to have stated that his experience in gun manufacture convinces him that this is not a serious obstacle. The advantages which would grow out of a direct utilization of mineral fuel as mined are very obvious. While modern practice converts only 10 to 15 per cent. of the heat energy stored in coal into power at the crank shaft of a steam engine, it is believed that no less than 75 to 80 per cent. could be made available by the direct combustion of the fuel through explosion of coal dust.

It appears from an official report that the cost of the World's Fair buildings at Chicago has been $16,708,826, or twice the sum expended for the same purpose at Paris in 1889.

CONDITION OF THE

Hardware Trade.

WITH THE ADVANCE in the season a still further increase in the volume of business is noticeable, and trade may in a general way be referred to as in a very satisfactory condition. In some lines, however, there is complaint on the part of the manufacturers that the season's demand has not yet set in in full volume, the severe weather which has until recently prevailed having the effect of keeping back trade somewhat. Seasonable goods are especially active. Wire Cloth, Lawn Mowers, Freezers, Barb Wire, Steel Goods, &c., are moving very freely. The tone of the market does not show any important modification. Prices on the whole are quite well maintained, with slight advances in some lines. There is a good deal of complaint in regard to collections, which are sluggish and unsatisfactory in several parts of the country.

Advices from Chicago.—The volume of business in Shelf Hardware is of a satisfactory character and is now up to about that which is usually expected in April. The improvement which has taken place this month is in marked contrast with the comparative sluggishness of the first quarter of the year, when sales ran below the average for that season. The demand now is unusually heavy for Wire Cloth, Poultry Netting, Wire Screens, Screen Doors, Garden Tools and summer goods generally. Roofing Plates are moving much more freely with the advance of the building season. Bright Tin Plates are also in much demand. No special change in prices has occurred since our last report. Heavy hardware is in very good demand, all houses here reporting an excellent condition of business. The carriage-makers' strike is losing its force and is not felt to any considerable extent.

There is no scarcity of Poultry Netting in this market. One or two manufacturers may have oversold, and those having contracts with them may suffer a little inconvenience in securing stock from other manufacturers, but such ample preparations have been made by the latter to meet such a contingency that assurances are given the trade that a plentiful supply will be available. This statement is made to counteract the impression that there is a shortage and that prices may be materially advanced.

Notes on Prices.

Cut Nails.—There is a large demand for Cut Nails and the volume of business is entirely satisfactory. Prices are also fairly well maintained on the basis of $1.20 for carload lots at mill. A concession of 2½¢ to 5¢ is however made somewhat more freely than a week or two ago. New York quotations are $1.40 for small lots from store.

Advices from Chicago.—An increasing proportion of Cut Steel Nails is now being sold as the gap widens between Cut and Wire Nails, but Wheeling manufacturers are making themselves felt to a greater ex-

tent in this territory and prices are not so firm as they have been. Open quotations on factory lots are still $1.35 Chicago. Jobbers have slightly reduced their prices and now name $1.45 from store for small lots.

Wire Nails.—The market is firm at the same prices which ruled last week—namely, $1.55 f.o.b., mill, with Cleveland as the point of equalization for the West and Pittsburgh for the East. The demand from the large houses is not as heavy as before the late advance, their requirements for the near future having been pretty well covered, but the volume of business at present prices is large and the trade would not be surprised if another advance were determined upon. There is some disposition on the part of jobbing houses to undersell the manufacturers, as many of them are enabled to do this on account of having purchased large stocks at former prices. Small lots from store in New York are quoted at $1.80 to $1.85.

Advices from Chicago.—The demand for Wire Nails is exceedingly good from consumers of Nails, but jobbers are well supplied with stocks and are not doing much in placing new orders with factories. A peculiar feature of the recent trade is the very high average of orders caused by the great demand for fine Nails. Manufacturers' prices have been firmly maintained at $1.55 Cleveland, but it is possible that the meeting of the manufacturers at Cleveland may have slightly advanced this rate. Such action is expected by the trade. Small lots are selling from stock at $1.75.

Barb Wire.—A very heavy business is in progress, and prices are steadily maintained; $2.45 for Four-Point Galvanized in carload lots at mill is firmly adhered to, and in some cases $2.50 is asked. While the tone of the market is excellent there does not appear to be a disposition on the part of manufacturers to ask higher prices, as those now ruling are referred to as remunerative, and it is regarded as good policy not to encourage competition or cutting by unnecessarily high quotations. Small lots delivered in New York are quoted at $2.70 for Galvanized and $2.30 for Plain.

Advices from Chicago.—Manufacturers report that second orders are not coming in so well as they would like to see them, but heavy shipments are still being made on old contracts and prices are firm. The trade of this season is by no means as large as it was a year ago, but makers look forward to a better business later, arguing that it is simply postponed and will make itself felt in due time. Plain Wire is in heavy demand with consumers frequently telegraphing their orders to hurry shipments. Quotations are unchanged on factory lots at $2.20 for Painted and $2.60 for Galvanized. Jobbers report the Barb Wire trade running rather light for the season, and, therefore, a disappointment. They quote small lots at $2.30 and $2.70 respectively.

Shears.—The leading makers of Steel Shears have just perfected an organization to be known as the American Shear Manufacturers' Association. The officers are as follows: F. C. J. Wiss of J. Wiss & Sons, president; J. H. Clauss of the Clauss Shear Company, vice-president, and Henry T. Seymour of the Henry Seymour Cutlery Company, secretary and treasurer. The object of the association is to secure concerted action to prevent the excessive cutting in price which has characterized the market in this line for some time, and to establish more uniform prices which will yield the manufacturers a profit on the goods. A number of the principal manufacturers have already identified themselves with this movement, and it is expected that it will include others so that this line will be in a more satisfactory condition than has recently characterized it.

There has also been formed an association to regulate the price of Cast-Iron Shears, which includes the leading manufacturers of this class of goods. The price on these goods has been in a demoralized state for some time, but the market in this line has now a better tone.

Rope.—As a result of the condition of things referred to in our last report a reduction of ¼ cent per pound has been made in Manila, and the base prices for Cordage are now as follows:

	Per Pound. Cents.
Manila	8¾
Sisal	7¼ to 7½
New Zealand	6¾ to 7

These prices, it will be observed, are exceptionally low and are regarded by many large houses as affording an excellent opportunity for the advantageous placing of orders, as it is not unlikely that a reaction will occur before long.

Galvanized Pump Chain.—In accordance with the understanding reached by the associated manufacturers of Galvanized Pump Chain, the following prices are regularly maintained, terms f.o.b., factory:

	Per 100 pounds.
5 ton lots	$5.50
1-ton lots	5.75
500-pound lots	6.75
Less than 500 pounds	7.00

Bicycle Lock.—This Lock is put on the market by the Smith & Egge Mfg. Company, Bridgeport, Conn. The goods are sold from the following list, which in less than gross lots is subject to a discount of 50 per cent.:

No.	Per gross.
12, Corrugated Brass Shell, Nickeled	$60.00
32, Figured Brass Shell, Nickeled	75.00

The Matador Meat Slicer.—This article is manufactured by the Gwinner Mfg. Company, Hamilton, Ohio. It is sold to the trade at $9 each, subject to a discount of 40 per cent.

Needle-Point Saws.—The following is the price-list of the Needle Point Saws put on the market by the S. A. Haines Company, Indianapolis, Ind. It is subject to a discount of 40 per cent.:

Needle-Point Hand-Saws.

26,	28,	30 Inch,
$36.00	42.00	48.00 per dozen.

	Per dozen.
No. 16 Needle-Point Wood Saw Blades	$8.00
No 516 Wood saw, No. 8 Blade, Frame Red, List	12.50

Needle-Point One-Man Cross Cut Saw.

3	3½	4	4½	5	5½	6 feet.
$2.56	2.76	3.24	3.70	4.16	4.62	5.06

Needle-Point Cross-Cut Saw.

4	4½	5	5½	6	6½	7	7½	8 feet.
$3.20	3.60	4.00	4.40	4.80	5.20	5.60	6.00	6.40

The Columbia Fly Fan. — Matthai, Ingram & Co., Baltimore, Md., who are manufacturing the Columbia Fly Fan, quote the goods to the trade at $20 per dozen, with 10 per cent. discount in lots of less than one dozen, and 20 per cent. discount if ordered in full case lots of one dozen or more.

Family Grist Mills—Are manufactured by the Rogers Iron Company, Springfield, Ohio. The list price on their No. 1 Mill, which weighs 27 pounds, is $5, and that of No. 3 Mill, with Wrought Iron Legs, weight 44 pounds, $7. These prices are subject to a discount of 40 per cent. to the trade.

Glass.—The conferences of the National Window Glass Company in the East, to which we referred last week, have resulted in several important accessions to membership in the association, among which are included New Jersey Glass manufacturers, while New York jobbers of American Glass who are not already members of the National Company, are considering the matter favorably. The New York Importers' Window Glass Association have the matter of working in harmony with the National Company under advisement, though no definite course has been decided upon. The New York and Boston importers have arranged, however, for uniform prices. These consolidations tend to strengthen the Glass market, and to put it in a better condition than for some time past. At a meeting of the National Window Glass Company, held in Chicago April 11 and 12, a change in prices was made to apply only to territory west of the Alleghenies, going into effect April 17, as follows: Carloads of not less than 24,000 pounds, specifications to be sent within two weeks of order, for shipment in one lot to one purchaser, within 30 days thereafter, a discount of 80 and 10 and 2½ per cent. One hundred boxes or over, but less than a carload, in one lot to a single purchaser, discount 80 and 7½ per cent. Less quantities than 100 boxes, discount 80 and 5 per cent. The National Plate Glass Company, whose incorporation was noticed in our Glass review of last week, have not yet announced their plans, but it is reported that possibly all the plants in the country may be purchased by the National Plate Glass Company, which will issue stock in return. We are advised that the restriction put upon the output of the Plate-Glass plants in this country, and the consequent restricted amount that is allowed each dealer, is stimulating the importation of certain grades of Glass, for which importers have never had inquiries. Among these are Plate Glazing Glass and Glass for cheap mirrors. We understand that when an American Plate-Glass plant has produced its allotted amount of Glass it is shut down. Quotations

in all lines are well maintained as follows: American Window Glass, 2000 boxes at one time, 80 and 10 and 10 per cent. discount; carloads, 400 boxes, 80 and 15 per cent. discount; less quantities than carloads, 80 and 10 per cent. discount. Freight allowed on car lots and over, not to exceed 17½ cents per 100 pounds; less than car lots, f.o.b. at shipping point. French Window Glass, 75 and 10 and 5 per cent. discount. American Plate ranges in price from 50 and 10 and 7½ per cent. discount to 60 and 5 per cent. discount. Imported Plate Glass, 60 per cent. discount to 60 and 10 and 5 per cent. discount.

Old Rubber.—The following are the current prices paid for Old Rubber delivered in New York:

Car Springs, in ton lots, ℔ lb.	@	$0.03½
Rubber Shoes, in ton lots ℔ lb.	@	.04
Large Hose, ℔ ton	@	9.00
Wringer Rolls, ℔ lb	@	.04½
Wringer Wire Rolls, ℔ lb	@	.02
Syringes, ℔ lb	@	.05

Old Metals.—The following are the current prices paid for Old Metals in New York:

Heavy Copper	℔ lb 9½¢
Light and Tinned Copper	℔ lb 8½¢
Heavy Brass	℔ lb 7¢
Light Brass	℔ lb 6¢
Lead	℔ lb 3½¢
Tea Lead	℔ lb 3½¢
Zinc	℔ lb 2¾¢
No. 1 Pewter	℔ lb 14¢
No. 2 Pewter	℔ lb 7¢
Wrought Scrap Iron	℔ gross ton, $13.00
Heavy Cast Scrap	℔ gross ton, 9.00
Stove Plate Scrap	℔ gross ton, 6.00
Burnt Iron	℔ gross ton, 4.00

Old Rags, Paper, Etc.—The following are the current prices paid for Old Rags, Paper, &c., delivered in New York:

No. 1 White Rags	℔ lb	4 ¢
No. 2 White Rags	℔ lb	3 ¢
Mixed Rags	℔ lb	1½ @ 1¾¢
Blues and 3ds	℔ lb	1¾ @ 2 ¢
Hard Sized White Shavings	℔ lb	2½ @ 3 ¢
No. 1 White Book Shavings	℔ lb	2¼ @ 2⅝¢
No. 2 White Book Shavings	℔ lb	1½ @ 1¾¢
Light Book Shavings	℔ lb	⅞ @ 1 ¢
No. 1 Mixed Shavings	℔ lb	1¼¢
No. 2 Mixed Shavings	℔ lb	¾ @ ⅞¢
No. 1 Printed Books	℔ lb	1⅜ @ 1½¢
Ordinary Mixed Books	℔ lb	¾ @ ⅞¢
Newspapers	℔ lb	½¢
No. 1 Manila Paper	℔ lb	1⅛ @ 1¼¢
No. 2 Manila Paper	℔ lb	⅞ @ 1 ¢
Bogus Paper	℔ lb	⅝ @ ¾¢
Common Paper	℔ lb	¾ @ ⅞¢
Straw Chips	℔ lb	⅛ @ ⅜¢
Binders' Clippings	℔ lb	⅛ @ ⅜¢
Jute Butts	℔ lb	1¼¢
No. 1 Jute Bagging	℔ lb	1¼ @ 1⅜¢
Mixed Bagging	℔ lb	1 ¢
No. 2 Bagging	℔ lb	⅞¢
Hemp Twine	℔ lb	2½¢
Manila Rope	℔ lb	2¾¢
Jute Rope	℔ lb	1⅞ @ 2 ¢
Mixed Rope	℔ lb	¾ @ ⅞¢

Trade Notes.

THE TINNERS' MACHINERY & SUPPLY COMPANY, 9 Cliff street, New York, successors to Hibberd & Spinner, issue a handsomely illustrated catalogue and price-list of an extensive line of goods. In an introductory note to the trade they state that this catalogue is intended to present in compact form their line of machinery. Reference is made to the general excellence of the machines, as well as the quality of the material from which they are made; also the extent of the line covered. Following the introductory note is an alphabetical index. Information to buyers is given on one of the earlier pages and immediately after begin the illustrations with descriptions and prices of the various goods noted, commencing with bar folders, forming rolls, sheet iron folders, Niagara incased machines, Raymond's machines, &c. An extensive variety of tinners' stakes are illustrated and tinners' small tools. Firepots and tongs of all sorts are noted, and shears, circular and squaring. The catalogue is of interest to those engaged in sheet metal work and is attractively published.

THE ADAMS & WESTLAKE COMPANY, Chicago, issue a handsome catalogue descriptive of their manufactures. The pamphlet is bound in flexible dark-colored cloth, while the title is in red ink. The frontispiece is a view of the factory of the Adams & Westlake Company on Ontario, Franklin, Ohio and Market streets, the buildings covering an entire block. The catalogue is known as their No. 15, and is devoted to Lanterns, Lamps, Oil Cans, Sieves, Sifters, Water Coolers, Air Guns and sundry Hardware specialties, including Bath Tubs, Faucets for Oil Cans, Ice Shaves, &c. A special feature of the volume is the fine paper and excellent typography; the engravings are also well executed and printed. An alphabetical index in the fore part of the book enables easy reference to be made to the contents.

CLAD'S 1893 CATALOGUE, issued by V. Clad & Sons, 117 South Eleventh street, Philadelphia, Pa., has just come to hand. The publication of 25 pages is bound in tinted paper and gives illustrations, prices and particulars of a very extensive line of ice cream machinery and supplies. The great number of illustrations in the pamphlet, all given up to appliances for making ice cream, shows in an indirect way the importance of this cool industry and the magnitude of the business it supports.

THE BOSS WASHING MACHINE COMPANY, 212 and 214 West Pearl street, Cincinnati, Ohio, present an illustration and a few particulars of the Eli Washing Machine in an advertisement elsewhere, and invite the trade to write for particulars and terms.

THE FIRM OF HIBBERD & SPINNER, 9 Cliff street, New York, have been succeeded by the Tinners' Machinery & Supply Company, who will continue the same business in Tinners' Tools and Machines.

THE MERITS OF ROYAL MILK CANS are set forth in a card from Haslet, Flanagen & Co., 116 North Second street, Philadelphia, among which are claimed special advantages of strength and durability, making them excellent heavy shipping Milk Cans. Each Can has their patent Royal handle, which is a feature of strength and convenience. The finish is first class, and the price is right, they confidently assert.

HASLET, FLANAGEN & CO., 116 North Second street, Philadelphia, have just brought out the Royal iron enamel which they claim on the announcing card is a glossy jet black, and the best and most brilliant in the market. It is adapted for Grates, Fenders, Mantels, Stove Pipes, Registers, Coal Hods, Sinks and Oil and Gas stoves, or any purpose for which a permanent glossy enamel is desired. They say it will stand any degree of cold without chipping and is not affected by heat as it will last a year on stove pipe and retain its surface, making cheap pipe look like Russia Iron. It can be applied by any one, and is put up convenient for retailing. Appropriate to the season they say it can be reduced with turpentine and makes a superior walnut stain for fly screen frames and such work. As a finishing suggestion they say: Paint your stove pipe before putting it away for the summer and prevent it from rusting out.

THE COLUMBUS SHEET STEEL WORKS, Columbus, Ohio, will reorganize and be under the management of C. C. Moore. The new company will erect a modern plant and manufacture, in addition to their present line of goods, Patent Gutter, Corrugated Iron Sewer Pipe and Galvanized Iron. The new plant will be fitted up with the latest and most improved machinery, especially adapted to their requirements.

EDWARD LITTLE, manager of the estate of S. Whitnum, North Eleventh street and Driggs avenue, Brooklyn, N. Y., reports a busy season, with large orders for Galvanized Sinks and Leader Pipes. He states that he is now making a new variety of Pipe, which is destined to prove very popular with the trade. A new pickling bath has recently been placed in the works, making a total of five in all, with a capacity, it is claimed, for galvanizing the largest articles. The factory and offices are adjacent to all the ferries leading to New York City, and are, therefore, convenient of access. Mr. Little will at all times be pleased to see his business friends and furnish them with estimates when desired.

THE LALANCE & GROSJEAN MFG. CO., 19 Cliff street, New York, issue a notice to the trade under date of April 18, referring to their suit against the Haberman Mfg. Company and J. E. Moseheim, their auctioneer, which was decided last December in favor of the Lalance & Grosjean Mfg. Company. They refer to the circulars sent out by the Haberman Mfg. Company to the effect that an appeal would be taken. This appeal, it is stated, was taken to the United States Circuit Court of Appeals, being argued before Judges Wallace, Lacomb and Shipman, who handed down a unanimous decision on the 18th inst., affirming the previous decision, to the affect that the Haberman Mfg. Company had violated the patented process of the Lalance & Grosjean Mfg. Company, and that the injunction issued against them and J. E. Moseheim must stand. The Lalance & Grosjean Mfg. Company trust that the decision will be heeded by all, and that no coagulated, mottled, wavy or cloudy ware infringing their patent will find a purchaser, as they shall hold dealers responsible for their infringements. They say that those who report infringements will be leniently treated, but that those who fail to do so will be prosecuted and made to pay the full measure of damages.

THE CAPITAL STOCK of the Detroit Sheet Metal & Brass Works, Detroit, Mich. has been increased from $100,000 to $150,000.

THE S. OBERMAYER COMPANY of Cincinnati, Ohio, have been appointed sales agents of the Blakeney cupola.

THE PITTSBURGH STEEL HOLLOW-WARE COMPANY of Allegheny, Pa., were granted a charter last week with capital stock of $50,000. The incorporators are Jno. S. McIntosh, Jas. McNaughner and Daniel McNaughner.

AMONG recently authorized corporations in Illinois are the following: The Hinson Car Coupler & Mfg. Company, Chicago; capital stock, $2,650,000; incorporators, Joseph E. Forsyth, Erskine R. Merrill and James P. Ennis. The Chicago Wind Motor Company, at Chicago; capital stock, $30,000; for the manufacture of Wind Motors, Pumps and Towers; incorporators, Frank A. Hecht, A. B. Peterson and Albert Raymond. The Shilvock Mfg. Company, at Cragin, Cook County; capital stock, $25,000; for the manufacture of iron, brass and copper goods for plumbing and for enameling; incorporators, Francis L. Shilvock, Ernest C. Shilvock and Albert M. Woodward. The Taylorville Mfg. Company, at Taylorville, capital stock, $15,000; to manufacture wind mills, tanks, towers, pumps, &c.; incorporators, H. B. McCaslin, N. Gandy and H. S. Willey. The Sykes Steel Roofing Company, at Chicago; capital stock, $50,000; for the manufacture of roofing;

incorporators, R. G. Sykes, C. O. Hart and H. G. Murphy.

THE GRANT CORUNDUM WHEEL MFG. COMPANY, whose plant at Chester, Mass., was burned recently, will seek a new location for building, probably in the West, where the greater portion of their product is marketed.

THE APOLLO IRON & STEEL COMPANY of Pittsburgh, with works at Apollo, Pa., manufacturers of galvanized iron and terne plates, have recently purchased considerable property in Apollo, which will be used for the extension of their present plant. Just what the nature of these improvements will be has not as yet been determined by the firm. We are advised that the report that a Bessemer plant would be erected on the property is without foundation.

THE PECK, STOW & WILCOX CO., recently received an order for upward of a thousand mills for grinding coffee to be shipped abroad.

THE GEUDER & PAESCHKE MFG. CO. of Milwaukee, Wis., have been obliged by the ever increasing demand for their goods to add very largely to their machinery for the manufacture of Tin and Galvanized Iron ware. They have just put in one of the newly patented wiring machines brought out by G. A. Crosby & Co. of Chicago, having been among the first to make practical use of it. They are now busily engaged in making up a stock of coal hods for the fall trade. In past years they have always been oversold in this line, but expect to be in shape to meet all demands this season. The company are now very extensive manufacturers of Galvanized Ironware. This ware they make from Sheet Steel and galvanize it after it is made up by coating it with molten zinc, which fills up all seams and crevices, and makes the completed article strong, durable and absolutely rust proof.

THE WILLIAM SCHOLLHORN CO., New Haven, Conn., have so far recovered from the effects of the recent fire at their works that since April 13 they have been running full time, and before long they hope to be entirely free from any hindrance occasioned by the fire. It will be remembered the damage was confined principally to the Shear and Plier departments.

HART MFG. COMPANY, Cleveland, Ohio, announce that the contract heretofore existing between them and H. A. Rogers, 19 John street, New York, whereby he acted as the company's agent in New York, has been terminated, and in future orders for Duplex Die Stocks should be sent to the factory in order to secure bottom prices. The company report business as very good, their trade for the past two months having been 25 per cent. greater than for any former similar period.

WE UNDERSTAND from the Clayton & Lambert Mfg. Company, Ypsilanti, Mich., that they are happy to be able to inform their many business friends that even the immense force of a cyclone seems to have recognized as a genial friend the famous blast of their No. 1 Fire Pot, for though it demolished buildings on all sides of their factory, it left that building comparatively unharmed. The firm are, therefore, able to fill all orders promptly.

THE STUART & PETERSON COMPANY, Burlington, N. J., in a circular issued under date of April 17, state that on March 9 the engine at their works in Philadelphia was stopped preparatory to removing to their new plant at Burlington, N. J. An idea of the magnitude of the undertaking will be understood from the statement that they forwarded by boat and rail 48 full carloads. They announce that after one month and eight days shut down they are again running with improved machinery and better facilities.

FLASHINGS.

GARA, MCGINLEY & CO., 13 South Seventeenth street, Philadelphia, Pa., have just been awarded a contract for the sheet copper and glass work on the skylights, gable ends and lobby lights of the Pennsylvania train shed at Broad street station, Philadelphia, which is said to be the largest unsupported single-roof span in the world. The firm are also doing the lateral skylight work, glass gables, tin roofing, galvanized, corrugated iron work, galvanized iron cornices, &c., on the Terminal Railroad Association Building, St. Louis, Mo., which covers a plot of more than four squares in area, or 600 x 700 feet.

THE BRITISH CONSUL GENERAL in Colombia, in a recent report to his Government, says that Great Britain takes the lead in supplying metal roofing material to that republic, sending there 226.6 tons to every 24.1 tons supplied by France and 6.7 tons by the United States.

A STEADY and satisfactory growth of business is reported by L. D. Berger of 224 Arch street, Philadelphia. This has resulted from a thorough understanding of the requirements of the trade in tinners' trimmings and supplies and industriously striving to meet them. Continual additions have been made to his stock of goods, which is now very complete.

THE FIRM OF FALL & YATES, doing a general stove and hardware business at Morris, N. Y., was dissolved by mutual agreement on March 21 of the present year, James A. Fall retiring from the concern. The business will be conducted in the future by A. E. Yates at the old stand.

WE ARE IN RECEIPT of advertising cards from Eberts Brothers Company, Limited, Detroit, Mich., directing attention to iron and steel roofing of their manufacture; also to a full line of roofers' sundries. The second card refers to gravel roofing, the advantages of which are noted.

GARA, MCGINLEY & CO., 13 South Seventeenth street, Philadelphia, Pa., distributes some interesting matter in the shape of circulars directing attention to their extensive line of sheet metal manufactures. One large sheet carries illustrations showing how old and dilapidated buildings, by applying sheet-metal work, can be given an entirely new and attractive appearance at comparatively small cost. On the back of the sheet are illustrations of cornice and window caps of various styles. Another sheet shows a handsome residence, illustrating the possibilities of sheet-metal work. All the ornamentations on the building illustrated are of sheet metal, with roofs of metal, tile or slate. Sheet-metal bay windows, oriole, chimney casings and ventilators, skylight and conservatory work, crestings, wall copings and tops, finials and vanes, door and window heads, cornices, frieze, hip and ridge moldings, panels, balustrades, posts, rails, &c., of balcony and conductors.

THE AMERICAN ROOFING COMPANY, St. Louis and Cincinnati, report an active trade in both plants. Their St. Louis plant is being improved by the introduction of new machinery, among which is a new automatic brake, new double crimper, and a new 10 foot power shear. This new machinery will enable them to increase their output, which is very necessary, as they are at present pushed to fill their orders, and the spring trade promises to be very large.

E. M. SHOUPE, Aurora, Ohio, has sold out his stock of tin and hardware and removed to Dayton, Ohio, where, with C. A. McFarland, he has organized the Dayton Roofing Company, for felt and iron roofing.

Requisites of Modern Steam Heating.

Notwithstanding the rapid growth in popularity of hot-water heating, steam heating will continue to be extensively used, particularly in the larger class of buildings, and in all buildings where steam is extensively employed for power purposes. The modern steam heating contractor will necessarily be obliged to make intimate acquaintance with the steam specialties necessary to effective work in particular cases. The business of manufacturing appliances of this kind has grown to be a large industry, and a variety of nearly every specialty is presented to the choice of the steam fitter. Intelligent men do not shut their eyes and draw from this variety, as in a lottery, any appliance that chance may dictate; but they acquaint themselves with the merits and demerits of each. The particular mechanism of different appliances claiming public favor and the principles of their construction constitute an interesting and profitable field of study, and in mastering them one can scarcely fail to become expert in nearly the entire theory of steam generation and its utilization either for power or heating. The primary sources of information upon the subject of steam heating specialties are the printed descriptions of them in manufacturers' catalogues and trade circulars, or such descriptions of them as appear in the columns of trade papers. Of these, those published in the better class of trade papers are, as a rule, the most satisfactory. In too many catalogues the descriptions are not always clear enough to be easily understood even by those already well versed in principles and in the practical use of steam. Still less are they clearly comprehensible to a large class of steam fitters whose opportunities for gaining theoretical and practical knowledge have been limited by circumstances, yet who are obliged to resort to the use of such appliances in special cases.

Examples of Such Failures.

Without naming any catalogue or trade circular, examples of failure to clearly set forth the principles of construction may be adduced. A case in mind is that of an engineer in charge of a steam heating plant in an office building who was unable to comprehend a circular describing an automatic air valve, and had to seek elsewhere for an explanation of how it worked. The circular was little help in any respect except in its pictorial illustration, which was good enough, and from which one thoroughly acquainted with the general principles upon which devices of this class work could, after a little consideration, determine the operation. To the engineer, however, the circular was merely waste paper and yet he was by no means so ignorant that a description, prepared as it ought to have been, would have failed to make him understand the valve and its operation easily and completely. In another instance a steam fitter in a New Jersey town, whose experience was limited to some half a dozen small jobs in which he had been fairly successful, found it necessary to use a steam trap for returning water to a boiler. In his desk he found a catalogue of steam appliances, in which the subject of simple steam traps for draining pipes, radiators, &c., and traps for returning steam to boilers was so mixed up and muddled, without any clear explanation of either of these to him novel appliances, that he actually made the mistake of ordering a draining trap instead of a return trap. That this man was not below the average in common sense is shown by the fact that he has succeeded as a steam fitter, and is now doing good work, and lots of it. It was the catalogue that was on this occasion deficient.

Out of Working Hours.

How many employers know or care where and how their apprentices or shop hands spend their leisure hours after the day's work is done? Usually the men and boys after leaving the shop are as completely lost to sight and knowledge until the following morning as if the earth had swallowed them up. Yet this matter, looked at in a common sense light, has a very important bearing on the efficiency and trustworthiness of employees, and it is one that is well worth consideration by all those who have youths working for them. Why not take a kindly interest in the tastes and pursuits of the boys out of working hours? They are not machines set a-going to grind out so much work per day, and then stopped to rest and do nothing at all until the next day's labor shall begin. Very often they have worthy tastes which may be easily encouraged by an exhibition of interest, while indifference may crush them. There may be points of contact where social intercourse with their employer will work to the benefit of both. Many young men desire to improve themselves in their trade after hours, and encouragement and assistance from the boss as to lines of study, &c., will stimulate them to perseverance in this line. Opportunities of lending a helping hand in many ways to the boys out of hours may be easily found without any semblance of interference with their liberty. Tact and a good heart will soon establish a feeling of confidence toward the employer who exercises them. Boys who may be living away from any home associations may often, by a little interest in their studies or amusements, have a bias given them which will be of incalculable good in the development of their characters. The establishment of confidence between employer and employed which would result from intercourse out of hours would tend to renewed interest in his duties and a more accurate and conscientious performance of them on the part of the boy. The employer would also discover whom he could trust to carry out work intelligently and faithfully without the necessity of constant supervision.

Salesmen and Prices.

A little "nerve" is often of great value to a salesman and consequently to the house which he represents. In some staple goods on which prices have long been soft salesmen have recently scored material advances by asking better rates and sticking to them with the determination to get some profit for their employers on the business turned in. It is too frequently the case that salesmen hasten demoralization by advising their principals that others are cutting prices when the trouble is either imaginary or confined to a few small concerns who would soon have such business as they need and then withdraw from competition. A salesman's function is, of course, to sell. If he cannot make sales he may soon find himself unattached. He is, therefore, measurably excusable for forcing the market at times so that he can get business. But that man is a prince among salesmen who is keen to perceive when he can obtain better prices.

The Cyclone Season.

The return of spring has brought with it unpleasant conditions not usually associated with the season that budding poets love. The daily papers for the past week have teemed with accounts of the ravages committed by violent wind storms. Cyclonic disturbances have prevailed over a very large portion of the country. The North has suffered as severely as the South, and residents of highlands have fared no better than the dwellers of the plains. Whole communities have been suddenly overwhelmed with destruction by the fury of the winds, and many lives have been lost. The damage to property has been very heavy, although there is no means of forming even an approximate estimate of the aggregate losses sustained throughout the country during the recent stormy period. A winter of great severity and long duration, bearing with much hardship on many business interests, has thus been followed by something even worse.

Meteorological experts explain the phenomena of the destructive winds in easy fashion, but allege that their prevalence over such a broad expanse of country almost simultaneously is a new feature of such disturbances. Cyclones and tornadoes are no longer to be classed as belonging to the tropics, but are now recognized as part of the natural phenomena of the temperate zone. Tornado insurance has been carried to a limited extent in localities in which there has been one of these visitations, but it will be very singular if such insurance does not assume large proportions after the occurrences of this spring. The statement has too frequently been made in print, after a thrilling account of the destruction wrought by a cyclone, that none of the sufferers carried any tornado insurance. The lesson has been taught and the practical application will be made.

The Columbian Naval Celebration.

Forty war vessels, representing the naval forces of ten powers, assembled in the harbor of New York this week to celebrate the four hundredth anniversary of the discovery of this continent. The past three days in New York have been devoted to a series of ceremonials and festivities almost unparalleled in history. The naval powers of the world have sent some of the finest types of their modern men-of-war to do honor to the memory of the great discoverer; and the proceedings of Wednesday, Thursday and Friday have fitly ushered in the great international fair, the doors of which will be thrown open on Tuesday next. New York has done herself honor and the nation credit by the graceful hospitality she has extended to the nation's guests. Banquets, balls and festivities have supplemented the more formal ceremonies of the week and have filled up the days and nights with pleasure. Unfortunately, the unpropitious weather of Thursday marred to some extent the great pageant on the Hudson River, but rain and mist were unable to dampen the spirit of international good will and general happiness which prevails or to spoil the grandeur of the spectacle. The great ships of all nations lying together at unity in two long lines for review by the president of the United States, was a sight which can never be forgotten by those privileged to view it. Friday's skies were bright and all conspired to make the land parade of that day a complete success. Such events make history, and the Columbian naval celebration of 1893 will be one of the red letter events of the century. The array of war ships of every type was striking as demonstrating the wonderful evolution which has taken place in maritime architecture. The contrast between these floating giants and the little Spanish caravels, faithful reproductions of the primitive craft in which Columbus and his associates crossed the unknown ocean, was an education to the observant mind. Such international celebrations as those of this week are happily a feature of the present age which is becoming more marked, and which can but tend to mutual benefit and good will the world over, even when the objects which come together for mutual comparison are engines of destruction. The splendid contingent of United States cruisers which took part in the ceremonies gave gratifying proof of the advance of this country in the line of naval defense.

Preserving the Forests.

A generation of men has risen which clamors for the preservation of our forests, lest the land be wantonly despoiled of its chief adornments, its mountains denuded, its streams dried up, its reservoirs exhausted, and a powerful agency for equalizing the temperature throughout the year cease in a measure to exert its benign influence. Moreover, many of the most charming mountain retreats, like those of New Hampshire or the Adirondack region in New York, are liable to be perpetually marred, if not obliterated, unless an authoritative arm is extended to arrest the process of spoliation witnessed from year to year. It is therefore gratifying to observe that many State Legislatures, acting as by common impulse, are moving simultaneously to effect the same end.

The prairie States were among the first to advocate arboriculture. Their province was not so much to preserve as to restore and rehabilitate. Prairie fires, perhaps more than any other agency, had reduced a vast expanse of territory to a desolation, possible of reclamation only as the result of artificial irrigation and a systematic restoration of forest trees. Thence arose a conviction of the necessity for the appointment of forestry commissions, arbor days, &c., until at last the familiar line, "Woodman spare that tree" becomes a positive prohibition rather than a plaintive plea. At the present time formidable syndicates of capitalists are getting possession of all the most valuable timber lands in the country, from Maine and Michigan to the everglades of Florida, and making incursions into the most secluded regions of Canada, in order to feed the capacious maw of the lumber mills being erected at every shipping point accessible either by railroads or navigable waters.

The general Government interposed seasonably to save the magnificent redwood trees (*sequoia gigantea*) of the Yosemite region and Yellowstone Park in Wyoming, but it remained for the several States, each within its own jurisdiction, to supplement the work initiated in the national domain. New Hampshire has taken action in behalf of the White Mountains to hold in check the vandal hands of scheming speculators bent only on private emolument. The State of New Hampshire has asserted its powers of eminent domain in the protection of those who may wish to purchase portions of the existing forest lands at fair prices. The new law in that State, like the present law in Massachusetts, authorizes the State to take and protect the gifts of land which are made by its own citizens or by the people of other States, and to build roads or paths over these domains, but forbids that they should ever again be used for private purposes. Thus the threatened destruction is arrested. In like manner the Legislature of New York, in passing the Adirondack Park bill, establishes a reservation which insures its protection by placing the entire region in control of a Forest Commission invested with adequate authority. This is a happy consummation of the efforts to save the Adirondacks which have been made in a desultory way for several years. The tract covers at present about 500,000 acres of forest land lying in six contiguous counties, including the islands in Lake George, and provision is made for its future enlargement. Maine is also waking up to preserve the forests in the Androscoggin region, and a bill is now before the Pennsylvania Legislature to stop the denudation of the forest area within that State.

This apparent though independent concert of action is a hopeful augury. And another ground of assurance in regard to forest preservation is found in the declaration of an expert of the Geological Survey, who maintains that the area of forest in the United States is as large as when the country was first discovered, so rapidly do old farms return to woodland where the rural element in population gives way to the advance of manufacturers and commerce.

A Negro Manual Training School.

In a 60-page edition, largely given up to advertisements of patent medicines, the *Daily Inter-Ocean* of Chicago celebrates its twenty-first birthday. There are various interesting articles in the colossal edition, one being on a manual training school for negroes at Tuskegee, Ala. This establishment, the Tuskegee Normal and Industrial Institute, was founded but a short while ago by one of the negro graduates of General Armstrong's colored schools at Hampton, Va., and has grown and systematized rapidly, consisting now of a large brick building, where the various workshops are housed, a saw mill and farm buildings with numerous cottages, all devoted to the industrial training of the negroes of the district. It is managed and taught by negroes, and no white man sets his foot in the institution except as a visitor. The establishment is said to be extremely well conducted, and the manual training given to its scholars thorough and efficient. Besides farming and cognate industries, carpentry, tinsmithing, harness making and shoe making are taught, and it is said that the buggies and carts, harness, shoes and tinware turned out from the school have a more than local reputation, and are eagerly bought up by the surrounding business people and planters on account of the honesty and excellence of their workmanship. As time goes on it is proposed to greatly extend the sphere of operations, and plans are contemplated for the establishment of industrial training here on a very extensive scale.

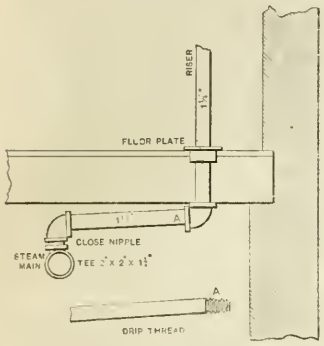
Dr. C. G. Hussey, a pioneer in the Copper and Steel industries, died at his home at East End, Pittsburgh on Tuesday morning, the 25th inst. For many years Dr. Hussey was connected with the firm of Hussey, Wells & Co., and Hussey, Howe & Co., large steel manufacturers of Pittsburgh and now known as Howe, Brown & Co., Limited. He was also the senior member of the firm of C. G. Hussey & Co., manufacturers of Copper, which firm has been established in Pittsburgh for many years. He was in the ninetieth year of his age and sustained an injury last week which has resulted in his death.

STEAM AND HOT WATER.

One-Pipe Connections.

BY HELIOS.

In Fig. 1 is shown a one-pipe connection from the main steam supply pipe from the boiler to the riser that supplies steam to a radiator on the upper floors of a building. This connection is taken from the top of



One-Pipe Connections.—Fig. 1.—One-Pipe Connection from Steam Main to Riser.

the main steam supply pipe so that dry steam will flow to the radiators. The tee in the main supply pipe is turned back a little from a vertical position, so that the branch pipe will pitch up from the main steam supply pipe and all condensation from the radiation will drip back into the main

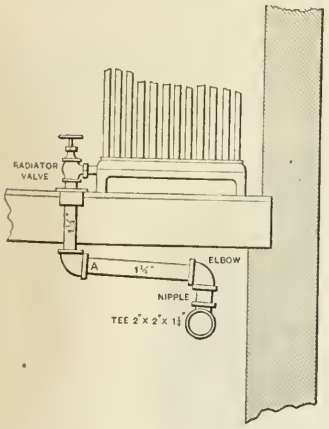


Fig. 2.—One-Pipe Connection from Steam Main to Radiator.

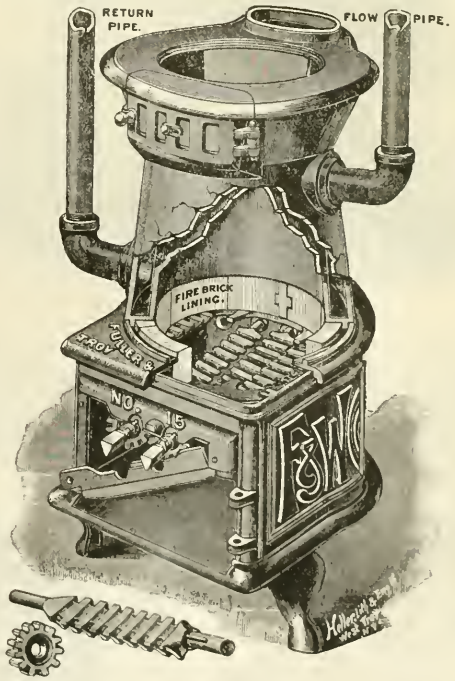
steam supply pipe. A nipple is screwed into the tee, and on the nipple an elbow, then the branch pipe that connects the main steam supply pipe to the riser is screwed into the elbow. The end of the branch pipe that is to connect to the elbow that is on the bottom of the riser, will need to have a drip thread cut on the end in such a way that the elbow will stand plumb to receive the end of the riser. To cut a drip thread on this pipe, as shown in Fig. 1, place it in a vise, take your stock and dies, placing a collar in the stock one size larger than the pipe you are to thread, take a pine stick and cut it wedge shape and drive in between the collar and the pipe to be threaded; hold the wedge in one place on the pipe, turn the stock and cut the thread. After this is cut screw on the elbow and set it by turning it around by hand until it has the right pitch, then mark it and screw up tight. With a little practice you will soon learn to cut a drip thread that will give any pitch to the pipe that you may require. This one-pipe connection must not be used where the distance from the main steam supply pipe to the riser is over 6 feet. The pitch from the main steam supply to the riser must not be less than 1 inch in a foot. This connection is used where all the condensation is dripped back into the main steam supply pipe and a return pipe is taken out at the end of the main steam pipe and carried back to the boiler.

Fig. 2 shows a one-pipe connection to a radiator on the first floor. This connection is made the same as explained in riser connection, Fig. 1, and the same rule will apply for the distance from main steam supply pipe to radiator connection. If the radiator has over 50 feet of heating surface make the branch pipe one size larger than the valve on the radiator, placing a reducing elbow on the end of branch pipe that joins to radiator connection. The above connections should always be used to connect radiators and risers, as it allows the condensation to drop back freely into the main steam main and insures a perfect working apparatus, free from noise of any kind.

All connections to radiators or risers for one or two pipe work should be taken from the top of the main steam supply, as it allows for the expansion of the piping. Never take a connection from the side of the main steam supply pipe, for as no allowance can be made for expansion of the pipe it will be liable to break the fitting in the main pipe.

The Fuller & Warren Company's Hot-Water Heater.

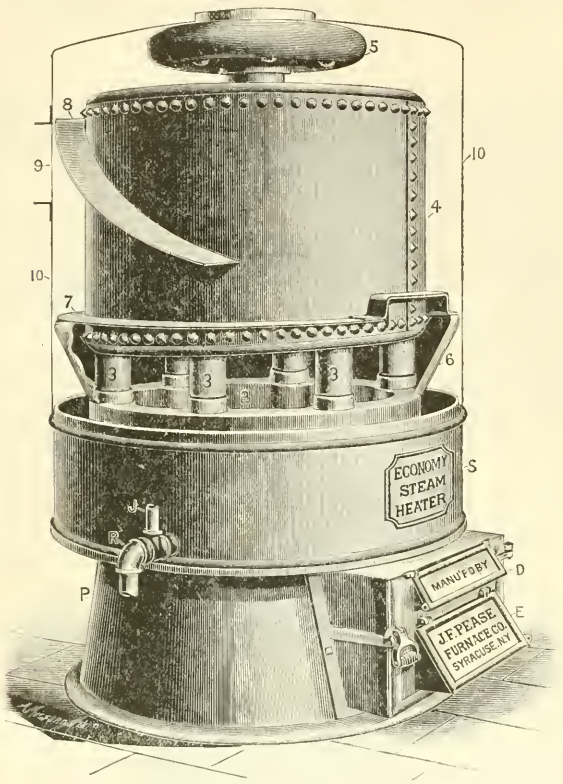
The accompanying illustration shows a broken view of the No. 12 and 15 hot-water heaters, which are being put on the



The Fuller & Warren Company's Hot-Water Heater.

market by the Fuller & Warren Company of Troy, N. Y., and which were designed to meet the demand for a small, low price heater of simple and durable construction. The special features to which attention is directed are that the water section is cast in one piece and that it is absolutely without joint or packing. The flue construction in the top of the boiler is so arranged that the products of combustion impinge directly upon all points of the boiler proper before passing to the exit pipe. This is accomplished by having the inside surface of conical shape and curved at the top to receive the direct action of the fire. The heater is furnished with triangular

grate for which claims of superiority are made. As shown in the cut there is a lining of fire brick at the bottom 4 inches thick, which, it is pointed out, prevents the fire from becoming chilled at its outer edge. The bricks are held in place by a clamp, which is shown at the back of the fire pot. This clamp has a lug extending through the back of the boiler and is fastened in place by a spring cotter. By removing the cotter the lug may be pushed in and the clamp taken out, permitting easy removal of the fire brick. By unbolting the strips supporting the grate shanks and sliding off the wheels the grate bars will fall out into the ash pit. The heater is provided with a large feed door, large and heavy top with large boiler hole, large fire pot and large and deep ash pit, and the makers point out that there are no flues to be cleaned. The No. 12 will, it is stated, heat 50 gallons of water per hour and the No. 15, 100 gallons per hour, from 50° to 212° F. The hight of No. 12 is 37¼ inches, diameter of fire pot 12 inches and the hight of the No. 15, 41 inches, and the diameter of fire pot 15 inches.



The Economy All-Steam Heater.—Fig. 1.—View of Heater with Casing Removed.

Economy All-Steam Heater.

The J. F. Pease Furnace Company, Syracuse, N. Y., have just brought out the Economy all-steam heater, which is illustrated in the accompanying cuts. The apparatus is modeled after the Economy low-down combination steam and air heater, the boiler being of the steel tubular type, as shown in Fig. 2. The manufacturers refer especially to the efficiency and general excellence of this form of boiler. The top and bottom flue sheets are of ¼-inch steel and the shell is a $\frac{7}{16}$-inch steel sheet, the flues in the smaller size being 1¾-inch and in the larger 2-inch standard gauge boiler tube. A feature to which attention is directed is that the bottom of the boiler pitches from the front to the rear, to facilitate pressure cleaning, the sediment which settles at the bottom being easily forced out by the steam pressure through the two rear nipple connections. In this way the bottom of the boiler, which is the most effective heating surface, can be kept clean. The boiler is tested before shipment to 80 pounds steam and hydraulic pressure. Fig. 1 shows the heater with the casing removed. The manufacturers refer especially to the large size of the ash pit, upon which the hollow pot rests, so as to give ample draft around the inside of the pot. The boiler is connected to the pot by six extra heavy connections screwed into the top of the pot, the joints being made tight by divided counter-sunk couplings, asbestos packed. A large steam outlet is screwed into a depressed boss, which is riveted to the under side of the top sheet of the boiler. This outlet opens into a steam chest shown at the top, and rises 1½ inches above the bottom of the chest, forming a circular dam, keeping the bottom of the chest covered with water, and preventing, it is said, the possibility of its being cracked by heat. Loss of heat from the pot is prevented by the outside casing S, Fig. 1, the upper casing being of galvanized iron and the top a piece of heavy cast iron. The products of combustion pass up the flues of the boiler, being prevented from passing up the sides by the cut-off skirts 6 and 7. They are then drawn down the outside of the boiler and deflected toward the front by the shield 8, one on each side. They are then passed between the deflectors and skirt up to the smoke outlet at 9. Attention is directed to the location of the return at R, which keeps the hollow pot full of water and insures the water being heated to a high temperature before it enters the boiler. The Economy all-steam heater is made in four sizes, with diameter of grate from 17½ inches to 27 inches; boiler surface, 80 to 190 square feet, and adapted to heat from 375 to 1150 square feet of radiating surface.

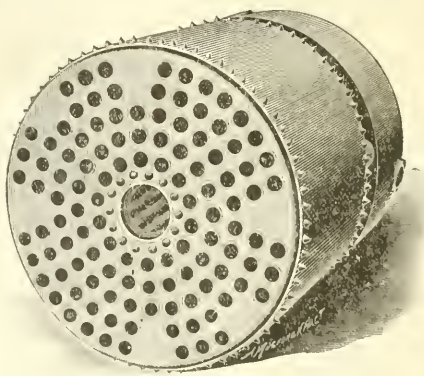


Fig. 2.—View of Steel Boiler.

HEATING NOTES.

Among residences in Chicago and vicinity that have been provided with the Capitol hot-water heater by John W. Mills, Ogden Building, Clark and Lake streets, Chicago, are those of Geo. Rounsavell, Wellington street; Julius Marks, Rogers Park; L. C. Platt, Lake Forest; John W. Low, Evanston, and Chas. Porter, Michigan City, Ind. Mr. Mills also has the contracts for steam heating in the following buildings: Addition to Needham apartment building; Chas. Thisslew's 15-flat building, Warren and Sacramento avenues; Whyland block, West Madison street.

Broomell, Schmidt & Co., Limited, of York, Pa., manufacturers of radiators, hot-water heaters, and Heatencook ranges, are compelled by increase of business to secure more room by the building of a new factory. Plans have accordingly been prepared and building operations commenced. The building will be of brick, 50 x 150 feet, two stories, and will embody some improved ideas and principles in relation to factory building. The main floor will be 3 feet above the street level,

and under the first 50 feet will be a basement 14 feet in the clear. In the basement will bu placed a new 80 horse-power boiler and a 50 horse-power automatic engine. Wash rooms and sanitary accommodations of improved type, for the employees, will also be located in the basement. The smoke flue from the boiler will be made of heavy iron, around which will be built a large ventilating stack with vent flues running from the different apartments. The office is to be located on the first floor front and is accorded a space 50 x 16 feet. Immediately in the rear of the office will be the stock and tool room. The pattern shop, drafting room and an extra stock room will be situated on the second floor, over the offices, and the balance of both floors will be used for the machine shop. The firm will also enlarge their foundry and make other improvements and additions to their plant.

THERE APPEARS to be a well-defined movement among the leading makers of high-grade heating apparatus in warm air, steam and hot water to discontinue contracting. Manufacturers are finding that the demands of their wholesale trade are making it inadvisable to attempt to continue in the retail business. The Excelsior Steel Furnace Company of Chicago adopted this policy some three years since and found it a great improvement over the old method of contracting. The consolidated boiler companies are doing the same thing. Some notable changes in this regard have but recently taken place. The change is one which cannot but be eminently satisfactory to the exclusively contracting firms and retail dealers.

AMONG THE RECENT CONTRACTS of the John Davis Company, heating contractors and jobbers of material, 69-79 Michigan street, Chicago, are the steam heating and power plant for Congress Hotel, which is also to supply the Auditorium Hotel; steam heating and power plants for L. Z. Leiter's new building, Ludington estate building, Phenix building and Presbyterian Hospital; power plant for the South Side Rapid Transit Company, and pipe work for the electrical fountain at the World's Fair.

A GENEROUS TRADE in the steam and hot water boilers made by M. Mahony of Troy, N. Y., is reported from the New York agent, Geo. Franklin, at 142 Centre street. The past severe winter has not found the capacity of the boilers in use inadequate.

"ALBERT A. CRYER & CO., Steam and Hot-Water Heating and Ventilating Apparatus," in large gilt letters, adorns the window of a fine office and showroom at 96 Centre street, New York. Albert A. Cryer having formerly represented the Richardson & Boynton Company in New England, is familiar with the work of installing heating plants and consulting engineering.

HYDRAULIC PIPE WORK for use with elevators is only one of the features of the business of Geo. Franklin, 142 Centre street, New York. His plant comprises a blacksmith shop for all kinds of forgings, and is provided with a steam hammer, cutting shears, drill presses for iron work, and pipe machines for cutting pipe up to 8-inch diameter, according to sketches furnished. Being agent for the hot-water and steam boilers made by Mr. Mahony of Troy, N. Y., he employs a number of expert fitters in the erection of heating plants.

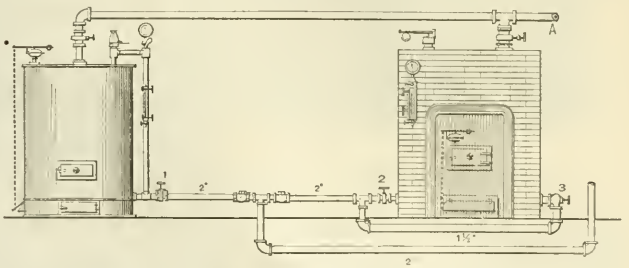
THE D. F. MORGAN BOILER COMPANY will be found in new and more convenient quarters at 85 Centre street, New York, after May 1. One of the contracts which they have filled was the installation of steam boilers in a building operation of 28 handsom residences at East Orange, N. J. Direct radiation of the latest design, elegantly finished, was used, ample to secure proper heat in all weather.

ONE OF THE FEATURES of the new headquarters of the American Boiler Company at 94 Centre street, New York, is a handsome table in the middle of the sample room on which are kept files of the trade papers that directly interest the heating fraternity. Specially prepared samples are coming which will make their showroom worthy of a visit to get new ideas in displaying goods.

THE ELWOOD IRON WORKS, Elwood, Ind., are putting up an extensive plant for the manufacture of the Holland steam and hot water radiators. They will employ 200 molders. They have made contracts with a Chicago concern, who will take their entire output. The Elwood Iron Works are incorporated, and have a capital of $100,000. The officers are John Holloran, president, and J. E. Jeffries, secretary. They will have their works in operation May 15.

Brick-Set and Portable Boiler Combination.

From J. P., *Brooklyn, N. Y.*—In reply to "Interstate," Philadelphia, whose letter appears in *The Metal Worker* of April 1, I inclose a sketch which shows my idea of the proper method of connecting the two boilers. Should the water return to the large boiler more freely than to the small one, I would check it by adjusting the valve No. 3. I have no doubt that it could be adjusted so as to equalize and give the proper quantity of water in both boilers.



Brick-Set and Portable Boiler Combination.

The report has been published of a special sanitary commission which was sent to Chicago by the well known English medical journal, the *Lancet*, to inquire, in the interests of English visitors to the World's Fair, into the condition of the water supply of the city. Numerous samples taken by the commission have been subjected to analysis by experts who report that the water of Lake Michigan compares, on the whole, favorably with the London supplies. The lake is, however, the recipient of a large proportion of Chicago's sewage, and it is reported that suspended matter is present in the water to an extent to make it unfit for drinking until filtered.

The British Ambassador at Constantinople advises manufacturers of goods for export to Mohammedan countries not to use trade-marks which may be liable to wound Moslem susceptibility. The custom house at Magador in Morocco has lately received an order from the Sultan not to admit certain cotton goods, cloths, boxes of matches, &c, bearing in Arabic characters the names of Mohammed, Hassan and Ali, these names being considered sacred.

Carborundum.

A new abrasive material has lately been patented by Edward G. Acheson of Monongahela, Pa., which appears likely to become of considerable importance. The material, which has been named Carborundum, is, as nearly as can be determined, a compound consisting solely of carbon and silicon, one atom of each element to a molecule, so that the chemical symbol of Carborundum is SiC. Physically it is a crystalline substance, very brilliant and usually of a dark color, although the color varies with the materials used in its preparation. The process of manufacture is simple and the materials inexpensive. As described in *Engineering News*, the process in general consists of subjecting a mixture of coke with silica, or silicate of alumina and a flux of common salt, to the action of the heat of an electric furnace. This is accomplished by forming an electric arc in the midst of the mass of material. When the chemical action is completed the products are removed from the furnace and the carborundum is freed from impurities by breaking it into small pieces and washing and drying it. The different-sized crystals are then graded.

The Carborundum Company, who have taken up the manufacture of the material, will, it is stated, shortly be able to produce about 500 pounds a day, when its present cost, the only obstacle which stands in the way of its general adoption for grinding purposes in place of emery, will, it is said, be reduced. One evidence of the extreme hardness of carborundum is that it has been successfully used for cutting diamonds, being the only substance other than the diamond itself which has ever been able to accomplish this work. The application of the material for cutting and polishing glass, porcelain, steel, cast iron and other hard substances is said to be steadily increasing.

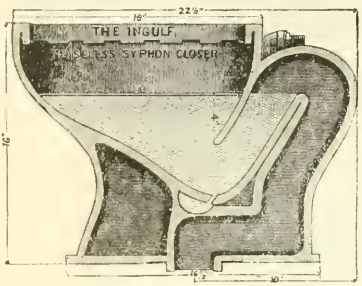
Speculation in our principal agricultural products is supposed to be mainly responsible for the derangement of foreign trade which makes possible the present large outflow of gold, threatening the stability of our currency system. Under a money pressure the prices of cotton, grain and pork products have declined, but speculation held up these prices artificially until the opportunity to sell on favorable terms was lost, foreign markets having been supplied meanwhile from other sources. At the same time foreign competition has been encouraged by the stimulus given to agricultural production in remote quarters of the globe. With their accumulated gold foreigners may now be able to control the prices of American products at the expense of the producers.

The red iron tower that has been a conspicuous landmark at Sheepshead Bay was tilted over by jack screws and will be sold as scrap iron.

PLUMBING AND GAS FITTING.

The Ingulf Noiseless Syphon Closet.

Louis Waefelaer, 54 Beekman street, New York, is now offering the Ingulf noiseless syphon closet, as here shown. In designing this article it has been sought to avoid the gurgling noise so common in syphon closets when in operation, and the manufacturer states that the Ingulf has overcome this objection. The suction of the large quantity of water in the bowl washing through the syphon is said to be so powerful that by a slight pull of the



The Ingulf Noiseless Syphon Closet.

chain it carries suddenly any quantity of toilet paper and water from the bowl through the trap.

Plumbing in New York State.

From J. E. T., *Rondout, N. Y.*—For the benefit of myself and other apprentices in the plumbing trade, please inform me what is the State law in regard to plumbing. I mean the actual law, not the law or rules laid down by the different boards of health or boards of master plumbers. I would like to have the matter explained very briefly, as I have seen several statements in print which seemed to differ regarding the work to be done. I wish to know what the law requires, and how the plumber can tell what he must do and what he must not do. I cannot find any journeyman who can explain the matter, and I think even some of the bosses cannot give the information. Another point is: Does the law govern all villages or only places over a certain population?

Answer.—We think our correspondent has probably become confused between the State law covering the registration of plumbers and the local regulations adopted by the different cities. The State law passed last year does not regulate the plumbing—that is, it gives no rules which must be followed in doing plumbing work. What it does provide for is the examination and registration of plumbers, and it leaves to the boards appointed for the purpose the work of drawing up rules to be followed in doing plumbing work. Therefore, the regulations describing how work shall be done in any locality depend upon the regulations adopted in that place and will vary in different cities. As the law reads it applies to the cities of the State excepting New York, Brooklyn and Albany. Villages and towns are not mentioned.

The New York Trade School Plumbing Exhibit for World's Fair.

Among the exhibits at the World's Fair from New York State the New York Trade School will have a rather limited space in which to present specimens of the young men's work after one season's course of instruction and practice. A plan of the exhibit is shown in Fig. 2. The samples of plumbing work sent on to Chicago consist of a horizontal double boiler, Fig. 1, and two basins, Fig. 3, with all of the fittings complete; also two cases of miscellaneous plumbing work executed by the young men of the class of 1891-92. One of the cases is shown in Fig. 4. Of the exhibits the horizontal boiler alone calls for any special comment, as, although it is to be classed as a "double boiler," it is in the sense that it is as though composed of two boilers set horizontally, end to end—not one within the other. The piping is all of galvanized iron. The water is to be heated in the usual way, in a water back, from which it returns to the boiler, but not in the usual direct manner. It is returned first to what is called a "receiver," whence it is distributed into both sections of the boiler by independent pipes. As an exhibit of hot and cold water supply, under a novel arrangement of pipes, it will be interesting to those who can readily grasp its features, whether as seen in the illustration we present herewith or when placed in position at the World's Fair.

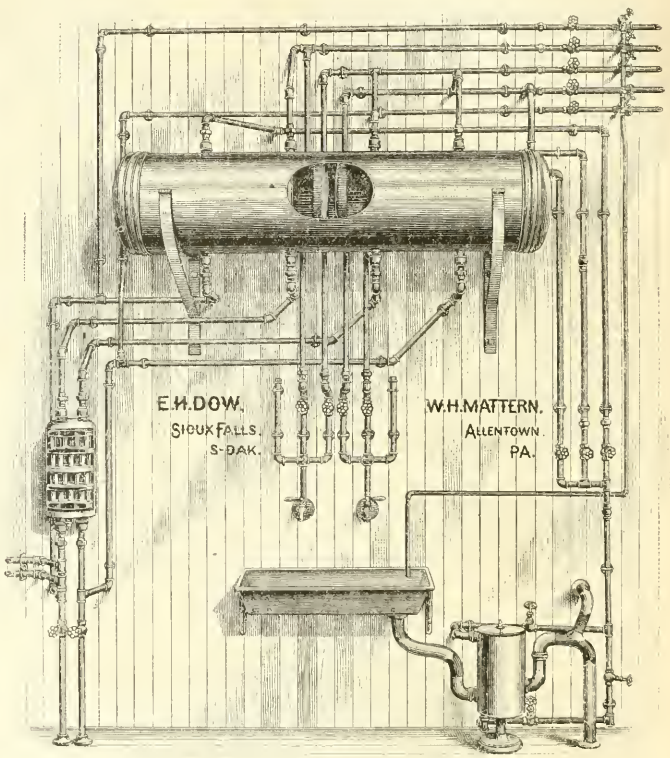


Fig. 1.—Horizontal Double Boiler.

NEW YORK TRADE SCHOOL EXHIBIT AT THE WORLD'S FAIR.

The specimens of plumbing work show the useful character of the instruction given at the school, as it enables young men to overcome obstacles which are likely to present themselves in country places where sources of supply are not always equal to the demand. It may be well to state that, in selecting the specimens of work for exhibit from that of the class of 1891-92, the school trustees had no option in the matter, as the exhibits had to be shipped to Chicago before the

finishing touches were given to the work of the plumbing class of the season just closed.

New Plumbing Regulations for Washington, D. C.

The new plumbing regulations for the city of Washington, D. C., which became operative on March 15 of the present year, are comprehensive enough to satisfy the most exacting sanitarian, and it is to be presumed that the master plumbers of the National Capital may be included in that category when their ten years' struggle for proper sanitary laws is considered.

This is not the first attempt at legislation of this character instituted in Washington. In December, 1882, a sanitary code went into operation, which, from its provisions and the mode of enforcement by the health authorities, was never popular with the master plumbers, who were then and have been since agitating for something better. The present regulations, adopted February 15, 1893, by the Commissioners of the District, and made operative on March 15, have been issued under authority of an act of Congress approved April 23, 1892, and styled "An act for the appointment of an Inspector of Plumbing in the District of Columbia, and for other purposes." The provisions of this act are ample, and include, besides general regulations to be followed by the Inspector of Plumbing when appointed, copious rules for excavations in streets, water service and connections with water mains, house sewers and connection with public sewers, plumbing and drainage of buildings, examination and registration of master and journeymen plumbers, gas fitters, &c.

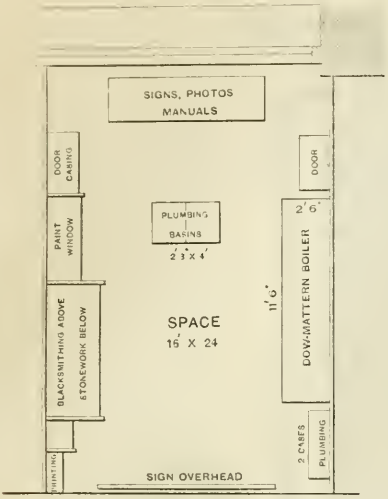

Fig. 2.—Plan of Exhibit.

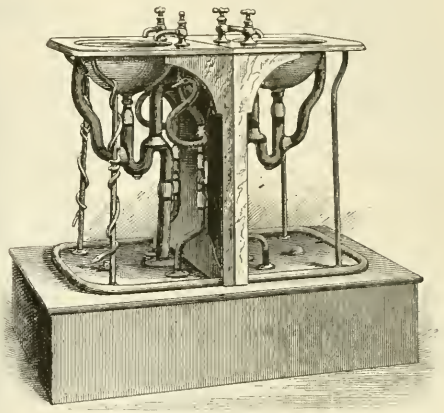

Fig. 3.—Basins with Connecting Pipes.

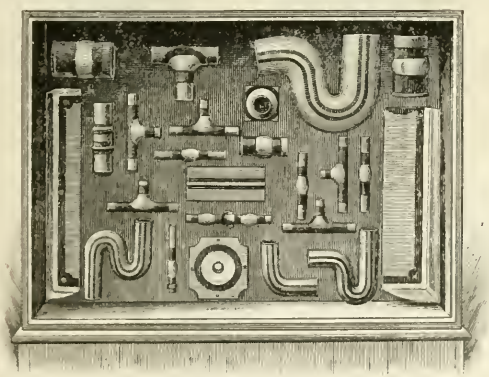

Fig. 4.—Case of Specimen Work.

NEW YORK TRADE SCHOOL EXHIBIT AT THE WORLD'S FAIR.

MASTER AND JOURNEYMEN PLUMBERS.

From and after May 1, 1893, all master plumbers and those desiring to become such must apply for examination before a board consisting of six members, viz.: The Inspector of Plumbing, one representative from the Water Department and from the Sewer Division, two master plumbers and one journeyman plumber. The applicant is required, if passed by the board, to register his name and address, take out a license and file a bond on the usual conditions for $2000 as indemnity for any loss occasioned to the District by any acts of his for a period of three years. After April 1, 1894, employing or master plumbers must be licensed, otherwise it will not be lawful to employ journeymen plumbers after November 1, 1893. No one can be employed as jonrneyman plumber who has not undergone an examination before and been licensed by the Plumbing Board and registered in the office of the Inspector of Plumbing. Other provisions require the filing of plumbing plans and specifications preparatory to permits being issued, with the Inspector of Plumbing, whose approval will be necessary in the first instance, and without which no subsequent alterations can be made in the original plans. The plumber is to be held responsible for violation of permit restrictions and for bad faith in the execution of contracts, and offenders are liable to suspension or revocation of licenses for violations.

PLUMBING AND DRAINAGE OF BUILDINGS.

Vertical soil pipes must be at least 4 inches in diameter and extend 2 feet above the building, the diameter to be increased 1 inch above roof in the case of three-story buildings, the increase to be made 1 foot below the roof. Where there are more than three stories the pipe is to be increased 1 inch in diameter every 25 feet above the third story. A Y branch with a 4-inch clean-out screw to be at the base of each vertical line of soil pipe, and pipes, traps, &c., are to be exposed to view where practicable. The provisions in relation to location and protection of pipes, the use of proper fittings, the trapping of all fixtures, and the venting of traps are very minute, but do not in the main differ from those in most existing regulations. The running of the vent pipe above the roof is not compulsory, but may, if preferred, be run into the vertical soil pipe above the highest fixture.

A somewhat peculiar provision is that which refers to the size of vent pipe (section 103) as being governed by the number of trap vents which connect with it. By this section it is required that where a building is three or more stories high and the traps of more than three water closets, or more than three traps or other fixtures, are to be placed in the first or second story, the vertical vent pipe is to " be increased in diameter at each story having additional fixtures, until the area of the said pipe at point of connecting the vent pipe of the highest fixture in the building shall be as nearly equal as practicable to the combined area

of all the vent pipes to be connected with it, or shall at least be equal to the area of the vertical soil pipe with which it is to be connected."

Another peculiarity observable is in the use of lead traps of 1½ inches caliber, in which case it is made permissible to use a waste pipe of 1¼ inches in diameter, though on larger traps the waste must not be of less size than the trap.

Lead safes or "linings" are called for under fixtures cased in wood, the safe waste to be run through the exterior wall of the building or to the cellar in the usual way.

Extra heavy cast-iron piping is called for in buildings, and the weight per lineal foot is required to be cast on the outer surface and where wrought-iron soil pipes are used they are to be of extra heavy galvanized iron.

The house drain and vertical pipes after being tested and passed may be coated with hot coal tar, and the usual running trap is called for with hand hole facilities for cleaning. The fresh-air inlet which is called for is to be 6 inches in diameter, that is, 2 inches greater than the New York laws call for. Unless all house drains are intended to be 6 inches the inlet will have to be reduced at point of connection with house drain so as to conform with the smaller bore of the house drain.

Lead water pipes are required to be what is known as "strong," which corresponds with A pipe ranging from ½-inch, weighing 2 pounds per lineal foot to 2-inch weighing 7 pounds per foot.

There shall be a gate valve on the supply, the free-water way of which is to be equal to the bore of the service pipe.

The general directions for setting water closets are in harmony with general practice. None are to be allowed in bedrooms, nor in any other room, apartment or vault which has not a window having an area of 4 square feet, opening to the onter air. Flushing tanks to be set over closets, flush pipe not to be less than 1¼ inches; all closets to have flush rim and have brass floor plate and rubber-gasket connection. Vent pipes for water closets to be 2 inches and those of other fixtures 1½ inches, unless over 20 feet, when they are to be 2 inches in diameter. Where water closets are set in yards they are to be located near the house and the flush tanks set within the buildiug, so as to guard against frost.

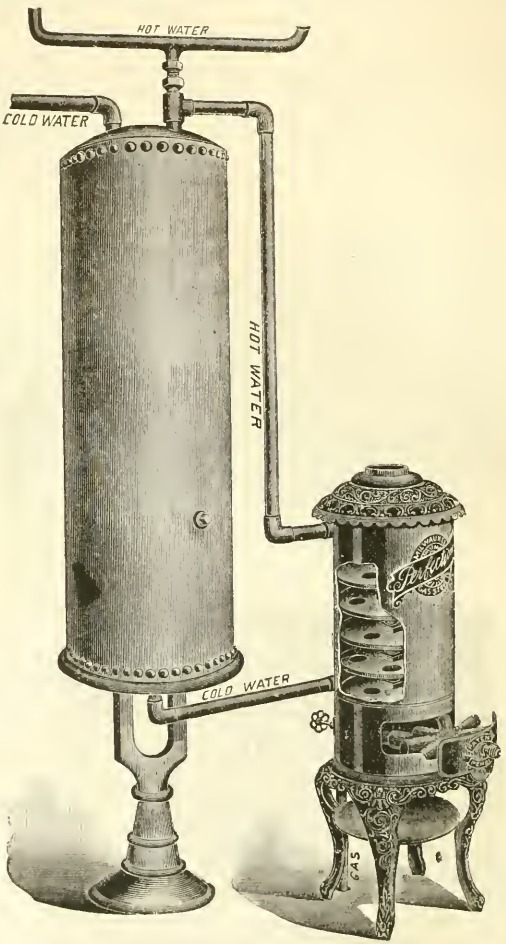
The pressure test to the extent of 10 pounds to the square inch is required of the plumber on all pipes in new buildings and the new work in old buildings. When the work is finally passed the Inspector of Plumbing issues a certificate to the plumber and a duplicate is furnished to the owner or authorized agent, if requested.

Wiping Stop and Waste Cocks.

From H. J. BAILEY, *Pittsburgh, Pa.*—I notice in *The Metal Worker* of April 15 an mquiry from "A. C. M." The answer is correct, so far as it goes. It states the fact that a good workman need not remove the plug of a key cock while wiping it on. To prevent trouble to all concerned in placing a key cock in position, the key should be removed, unless the workman is expert enough to make a homogeneous, clean-edge joint, with just the amount of heat necessary and no more.

The Perfection Water Heater.

The Milwaukee Gas Stove Company of Milwaukee, Wis., have recently brought out their Perfection gas water heater, which is herewith illustrated. As shown in the engraving, this water heater is cylindrical in form. It is 8 inches in diameter, 20 inches high, and has a double jacket to prevent loss of heat from radiation, the outer covering being made of Russia sheet iron. The interior is constructed in five sections, as shown in the broken view of one side. The flues and the spaces between them alternate in each section to retard the heat and secure the utilization of all the heat generated. Thus, very little heat is felt at the vent, and no chimney connection is considered necessary. The burner is of telescopic form, and is shown drawn out for lighting. When lit it is pushed back in place. There is thus no accumulation of gas in the water heater when lighting. The manufacturers state that 30 gallons of water are heated with it in three-quarters of an hour, while three baths may be taken in an hour. The consumption of gas is rated at 20 cubic feet per hour, and much less after the water becomes warm.



The Perfection Water Heater.

TRAPS AND VENTS.

WE HAVE RECEIVED from J. A. Brown, Riverhead, Long Island, N. Y., a sample of plumbers' wiping cloth which he is making and supplying to the trade. It is a fine quality of closely-woven cloth and of smooth texture. Mr. Brown thinks that the common bed ticking is too coarse to use for the purpose as it takes too long to break the cloths in.

S. DAVISON, 56 Beekman street, New York, has since last November been representing the Steel Bath Mfg. Company of Detroit, Mich., for the introduction of their goods in this territory. He says the bathtub made by them is selling freely, necessitating working overtime at the factory to execute orders, being now a full month behind in deliveries. This tub is a new feature in the plumbing business, designed to supply at moderate cost an article to take the place of the more expensive detached tubs where everything is exposed and any difficulty quickly reached. An order was taken recently for 15 of these tubs for some buildings at Ninety-sixth street and Fourth avenue in this city. Owing to want of space, the bathroom doors being but about 2 feet wide, it was found impossible to get the tubs in their places. The management, therefore, brought a trained workman, employed in the manufacture of these goods at their Toronto factory, to New York, who, taking off such portions as was necessary, succeeded in placing the tubs properly.

UTICA PIPE FOUNDRY, Utica, N. Y., for whom Charles Millar & Son are selling agents, issue a circular of cast-iron pipe for water and gas. They refer to the excellent record of this pipe, alluding to its special advantages, and furnish a partial list of new water works to whom they have furnished pipe as well as other water companies and railways among their customers.

THE GREAT WESTERN POTTERY WORKS have decided to locate at Kokomo, Ind., the pioneer gas city in the Indiana gas belt. They will manufacture fine sani-

tary goods as well as tableware. Their works will comprise eight buildings, all to be constructed of stone and brick, with slate roofs. They will have a floor space of 87,000 square feet, and will employ 500 hands. The Whitaker Supply Company, manufacturers of brass goods and other plumbers' supplies, will also build a factory at Kokomo.

DANIEL G. FINNERTY, vice-president of the National Association of Master Plumbers of the United States, issues from his office at Boston, Mass., 478 Boyleston street, under date of April 25, an invitation to the master plumbers of Massachusetts to attend a mass meeting at the Builders' Exchange, Knowles Block, Worcester, Mass., on May 1, at 1 o'clock p. m., for the purpose of organizing a State Association to affiliate with the National Association. Every master plumber in the State has been invited to attend this meeting, and it is hoped that as many as possible will be present and that Massachusetts may not be behind in association matters. It is mentioned in the call that the business of the convention can be finished in time so that all visiting delegates will be able to return to their homes on the same evening.

MCCAHAN & CO., 8 Central avenue, Baltimore, Md., distribute circulars illustrating and describing the Little Wonder gas bath heater of their manufacture. The device is described as a lighter edition of their Surprise heater, and is intended to come within the means of any one wishing hot water for bathing purposes. The boiler and case are of galvanized iron, strong enough for holding water while being heated, but not intended to stand reservoir pressure. Three feet of hose are furnished with each heater for connecting to cold water spigot. The capacity is nine gallons and heats the water hot in 30 minutes.

D'ESTE & SEELEY CO., manufacturers of plumbers' supplies and brass goods for steam, water and gas, have recently removed to 29-33 Haverhill street, Boston, Mass., occupying the entire five floors of a building 70 x 50 feet. The ground floor has been elaborately fitted up as a showroom. Almost the entire front is plate glass and the walls are of light colored tiling. A large variety of closets, tubs, &c., have been set up and are shown in operation. D'Este & Seeley Co. have been in business 25 years and have established several well-known specialties and made a market for a standard line of brass goods.

SMITH & WEBSTER, manufacturers of fine plumbing goods, 198 Lake street, Chicago, have purchased the marble works of Edward T. Moonan, at 103-105 West Monroe street, to which is to be added new and improved machinery for the manufacture of all kinds of marble, slate and soapstone work required in the plumbing business.

THE MASTER PLUMBERS' ASSOCIATION of Chicago, whose headquarters are at 197 Madison street, room 8, would be pleased to receive copies of catalogues from manufacturers of plumbing supplies, which will be placed on file for the use of the members.

THE EXAMINING AND SUPERVISING BOARD OF PLUMBERS of Niagara Falls, N. Y., has organized and elected F. W. Oliver president and W. W. Edwards secretary and treasurer. The other members of the board are Patrick O'Neill, E. Z. Burns and M. Talbot, M.D., the two latter being *ex-officio* members.

THE CAMDEN, N. J., BOARD OF HEALTH, at a meeting on April 24, passed an ordinance creating an Examining Board of Plumbers, and the following were appointed as members of the board: Messrs. Watson, Lewis, Hammond, Dr. Mosslander and Francis.

THE PEOPLE AND THE PLUMBERS OF GLOUCESTER CITY, N. J., are both happy in the new and improved water supply system just completed. It consists of 12 artesian wells located around an accumulating basin, each one of which has struck a water vein. The old supply is retained and with the better water which the analysis shows an improvement in the public health is expected. A probable increase of water users is what pleases the plumber.

IN PURSUANCE of an agreement between the master plumbers and the journeymen plumbers entered into last fall to go into effect on May 1, the standard wages will advance from $3.50 to $3 75 per day in New York City. In most of the shops this advance, we understand, will be made without hesitation.

The Chicago Master Plumbers.

The regular semi-monthly meeting of the Chicago Master Plumbers' Association was held at 206 La Salle street, Monday evening, April 24. It was decided to recommend to the Department of Health the substitution of heavy cast-iron drainage pipe instead of tiling in the confines of all buildings. Also that a board of examiners be appointed to determine the competency of each applicant for a plumbing license. It was recommended that all plumbing work be tested by the Department of Health, and a certificate given to the plumber when the work was properly done. A prize of $25 was offered for the best essay on "Sanitation," the subject to be treated under the following divisions: *a.* Should sanitation be fostered by legislation? *b.* Should legislation precede education? c. The extent of municipal or State authority in sanitary matters. As a further incentive to literary effort on the part of contestants, the prize essay is to be read before the National Association.

National Association of Master Plumbers.

The official call for the coming convention of the National Association of Master Plumbers, to be held in Milwaukee, Wis., June 13, is presented in the following announcement issued by President Jeremiah Sheehan from St. Louis, under date of April 25.

The Eleventh Annual Convention of the National Association of Master Plumbers will convene in Lincoln Hall, corner Sixth and Grand avenue, Milwaukee, Wis., at 10 o'clock a.m., Tuesday, June 13, 1893.

The Hotel Pfister, corner Washington and Jefferson streets, has been selected as National headquarters; rates, $4 per day and upward. Accommodations can also be secured at Pabst Hotel, $2.50 to $3.50 per day; Republican House, $2 to $3.50 per day, and Schlitz Hotel, European plan, rooms $1 to $2 per day.

As is customary, application was made for the usual reduced rates for delegates in the convention; but I regret to say that such reduction was refused. I give you a summary of the correspondence had with the Western Passenger Association, in whose territory the convention is to be held, and this office, in order that you may know what has been done in the matter.

On March 3 I made applications to the various passenger associations, receiving replies from all. The Western Passenger Association were to take the initiative, and their decision, if in the affirmative, would cause other lines to favor our application, and if in the negative their decision would be upheld by the other lines. The forms of the Western Passenger Association were filled out and returned, and same acknowledged by the chairman of the association, who stated that our application would be laid before the association in due time, and that this office would be advised of result. I will also state that the usual concession is a fare and one-third, three days' limit. Anticipating that many of the delegates would want to stop over and visit the World's Fair, I asked for an extended limit, but was advised that it would be impracticable. On March 14 I was further advised by the Western Passenger Association as follows:

"We beg to advise you that your proposition to make a rate of a fare and one-third on certificate plan from association points has been considered by our lines, but we regret to say that same failed to carry under our rules, and we are, therefore, unable to announce the reduction for this occasion."

I immediately wrote to the chairman of the association, why application had been nonconcurred in, and received the following:

"In reply will say that all matters of this character are subject to vote of lines in this association—a unanimous vote being required to make the proposition effective. In case of this meeting proposition was submitted for the usual reduction but failed to receive unanimous consent, and under the rules we were obliged to declare the proposition negatived. The lines voting in the negative have not assigned any reasons. Under our rules our lines are not required to assign any reasons for their vote; simply to record an affirmative or negative vote on such propositions as may be submitted to them, and it is not within the province of the chairman to ask for an explanation. World's Fair rates will be in effect at the time of your convention from all points in this association to Chicago and return, based on a somewhat similar reduction to that which is sometimes made to meetings similar to yours, and as in all probability most of your members will pass through Chicago, they can take advantage of the reduced rates to Chicago for the World's Fair, in buying thence to Milwaukee and return."

In view of the fact that the desired rates would not have allowed a stop-over privilege in Chicago, and that World's Fair rates will be in effect, which will be equally as good and in some cases better, as well as having an extended limit, I would, therefore, suggest that tickets be purchased to Chicago, thence to Milwaukee and return, as it is only a short distance.

The European Spelter Product.

Through the courtesy of the American Metal Company of New York, we are enabled to present the following statement, compiled by Henry R. Merton & Co. of London, of the production of spelter.

Spelter Production. *Gross tons.*	1892.	1891.
Rhine District and Belgium	143,505	139,695
Silesia	87,760	87,080
Great Britain	28,590	29,410
France and Spain	18,462	18,360
Poland	4,270	3,760
Austria	5,020	6,440
Total Europe	287,607	284,745

The American Metal Company estimate the spelter product of the United States at 77,650 gross tons for 1892 and 71,756 tons for 1891.

New Publications.

MUNICIPAL IMPROVEMENTS. A Manual of the Methods, Utility and Cost of Public Improvements, for the Municipal Officer. By W. F. Goodhue, C.E., member of the Western Society of Engineers. New York: John Wiley & Sons. 1893. $1.50.

To those citizens who suddenly find themselves called upon to fill a place in the councils of their city or town, or some other public office, and who have had little or no previous acquaintance with the questions regarding municipal improvements which must come before them, such a handy little work as that of Mr. Goodhue will be extremely useful. Avoiding in general the use of technical words and phrases, as well as mathematical tables and formulæ, the author has here given in compact form a great deal of useful information in regard to such public matters as come under the jurisdiction of municipal officers. Treating, as it does, of such important questions as sewerage, street-car lines, street sprinkling, lighting, water work, building laws, &c., the newly elected magistrate or councillor who is desirous of obtaining an intelligent acquaintance with these necessary subjects should find this a helpful little work. The last chapter, treating of "Cleanliness and Public Health," is particularly worth the perusal of all conscientious public officers.

A statement prepared by the United States mint director shows that the total specie holdings of the United States treasury and the great banks in Europe are $2,483,000,000, of which about $1,533,000,000 are gold and $950,000,000 are silver.

THE LETTER BOX.

Bending Tin Pipe.

From P. B., *Wilwaukee, Wis.*—I would like to be informed through the columns of *The Metal Worker* how to bend a 1¼-inch round tin pipe to a circle of about 1ft foot in diameter.

Answer.—Sheet-metal pipe that is to be bent is first filled with some substance that will allow the pipe to bend and at the same time keep it in shape as much as possible during the operation. Lead is used as a filling for some kinds of work, and is sufficiently hard to allow the wrinkles that are liable to form inside the bend to be pounded out and the pipe worked until it assumes the desired shape. Pitch is often used as a filling, and should be as hard as possible so as to bend without crumbling, and at the same time be sufficiently dense to allow such wrinkles as might form in the pipe to be pounded out. Pitch can be made by mixing tar with melted rosin until the desired density is obtained. It is probable a tin pipe could be bent by filling with lead or pitch, providing the metal was of sufficient thickness to allow for the stretching of the outer part of bend. An objection to the use of either of the above fillings is the difficulty experienced in removing them, which must be done by melting, and in the case of tin pipe would be liable to injure the appearance of the surface. Plaster of paris is sometimes used as a filling for pipes, and might answer in the present instance. One end of the pipe is to be closed by means of a wooden plug or by soldering on a cap. The pipe is then filled with dry plaster of paris, which is rammed in by means of an iron rod, so the filling will be as solid as possible. When the pipe is filled the remaining end is closed, when the pipe is ready for bending, after which, by opening the ends of the pipe, the plaster can be removed.

Stopping Leaks in Gosoline Stoves.

From C. H. H., *Valparaiso, Neb.*—What is the best way to stop leaks around the burners of gosoline stoves?

Answer.—The best plan to follow with gasoline stoves, when the burners and valves leak, is to repack them and turn them up until they are tight. To repack, unscrew the fittings, put new asbestos in the valves, examine all the threads to see that they are not broken or injured, and rub them with a coat of red lead before replacing. Better results are often accomplished by using ordinary hard washing soap instead of red lead.

Forming Wash Boilers.

From J. H. W., *Williamsport, Pa.*—In answer to "O. J. B.," Troy, N. Y., who wishes to know of an easy way of forming wash boilers: "Use a piece of 1 x ¼-inch steel formed to the curve of boiler, as long as the middle bend, and made pointed at the ends so as to enter the rolls with ease. Set the rolls so the boiler will go through without forming. Put the steel form in the rolls half way and make the first bend; then run the boiler along until the point is reached where the second bend is to commence, when the steel form is to be placed on the boiler and run through the rolls, thus making the second bend. The boiler is then to be run through the rolls as before until the point is reached where the final bend commences, when the steel former is placed on the boiler and the last bend made. Of course each size of boiler will require a separate former, but the expense is so little it should not prevent one from having a full set of these convenient articles.

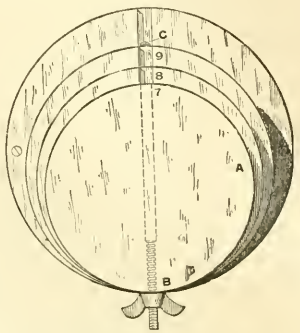
Joints in Lead Pipe.

From E. C., *Buffalo, N. Y.*—I would like to have an expression of opinion from the readers of *The Metal Worker* regarding the strength of joints made in lead pipe. Is not a well-soldered cup joint as strong as the usual wipe joint? While the cup joint may not appear as strong, it is one the tinner often finds convenient to make.

Note.—Experiments, as reported in a former issue of *The Metal Worker*, have been made with pipe known as single X strong, weighing 3 pounds 1½ ounces to the foot and joined by means of the wipe joint, cup joint and butt-sweat joint. Pieces of pipe 8 inches long were used for the tensile and elongation tests, and to make connection with the testing machine ¼-inch steel wire nails were soldered into the ends of the pieces. As 1 inch of each end of the pieces was made solid with the nails and solder, 6 inches of the pipe was left in which elongation could take place. The wipe joint was 2 inches in length and well made, as was the cup and sweat joints. As a result of the tests, the pipe broke in each instance, thus showing that the joints were stronger than the pipe. Pieces of the same kind of pipe, similarly joined to those mentioned above, were also subjected to hydraulic pressure, and in each instance the pipe burst instead of the joint. The conclusions arrived at from the above tests were as follows: The experiments are conclusive proof that the slightest of all joints, the butt sweat joint, is, when well made, fully able to stand 20 times the average pressure to which it is subjected, at least for a short time. But, on the other hand, past experience teaches us that the wipe joint has the greatest endurance of any solder joint providing that the wipe joint is well made and that the other joints be not allowed more contact surface for solder than the wipe joint. In practice the wipe joints are given more than double the hold upon the pipe that is given any of the other joints. As the subject of joints in lead pipe is one of interest to many of our readers, we would be pleased to have others give the results of their experience with the various joints mentioned.

A Home-Made Wash-Boiler Former.

From C. F., *Akron, Ohio.*—In *The Metal Worker* of March 11 "O. J. B." of Troy, Ind., asks how to form wash boilers without the use of a former. I understand by this that he wishes to form boilers without the use of a forming machine. I inclose set of drawings of a little machine that need not cost over $1.50. It is all made of hard wood, except two inch wood screws, one thumb nut and one long bolt about ½ x 16 inches in size, with one end turned up 1 inch at right angles with the length of the bolt. To use the former



A Home-Made Wash-Boiler Former.—Fig. 1. —Plan of Former.

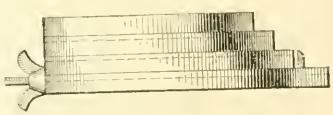


Fig. 2.—Side Elevation of Former.

the boiler body is caught by the end under the clutch C, as shown in the top view, Fig. 1, and if intended for a quarter circle is bent around the former to A, or if for a half circle it is brought around to B. To change from a 9-inch boiler to 7 or 8 inch the bolt or clutch, Fig. 3, can be taken from the former 9 and inserted in the hole above, which will set the machine for an 8-inch boiler, or it can be changed to the next hole for a 7-inch

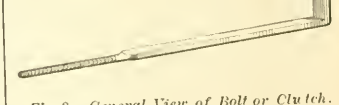

Fig. 3.—General View of Bolt or Clutch.

boiler. This will be further understood by referring to Fig. 2, which is a side elevation of the former. I think with the sketches and this brief explanation any tinsmith can understand its construction. I would only say in closing that wherever this former has been used it has given the greatest satisfaction.

ROOFING AND CORNICE.

Meeting of Chicago Cornice Makers.

The cornice manufacturers of Chicago met at the Grand Pacific Hotel Friday, April 21, to take action with reference to the building ordinance passed by the City Council, March 13, H. C. Knisely presiding. The ordinance prohibits copper and galvanized iron bay windows and light shafts being fitted with any combustible material. There are 150 manufacturers in Chicago, and it is claimed that the business of two-thirds of these would be destroyed if the ordinance be enforced. It is stated that there are over 10,000 metal covered bay windows in the city, and that there has never been an instance known where a fire has caught through the metal covering, and that such bay windows are safer than tin roofs, as fire branda could not lay on them. It was decided to form an association for mutual protection and to take such steps as may be necessary to have the act reconsidered. The following officers were chosen: President, H. C. Knisely; vice-president, G. Burkhardt; secretary, J. H. Perkinson; treasurer, A. W. Cooper.

The following is a copy of the petition to be signed by interested parties and presented to the city council:

To the Mayor and Common Council of the City of Chicago:

We, the undersigned cornic e manufacturers, cornice workers and tinners, also dealers in cornice makers' and tinners' supplies of the City of Chicago and vicinity, hereby petition your honorable body asking you to reconsider and repeal the following sections, Nos. 118, 132, 134 and 135 of the Building Ordinance passed March 13, 1893, relating to the construction of bay and oriel windows and light shafts.

Whereas, Your petitioners believe that these sections, if not repealed, will ruin manufacturers in the business and deprive the workmen of their means of livelihood and injure the city in general.

Whereas, Your petitioners further believe that the aforesaid sections were not fully considered at the time they were passed in your body. We further believe that had the meaning of these sections been fully explained and their effects known, they would not have been passed.

The obnoxious sections of the building ordinance against which the above action was taken are as follows:

SEC. 118. The inclosing walls of bay windows and light shaft walls shall in all cases be built entirely of incombustible material.

SEC. 132. Where sheet metal cornices or external sheet metal gutters are used, their entire frame work and covering shall be of metal, and the walls shall extend behind all such cornices or gutters along their entire light and a water-tight junction shall be made at the line of the wall between the roofing material and the sheet-metal covering of such cornices, or the sheet metal forming such gutters.

Wood shall not be used as the support of any gutter or cornice other than for such gutters as are on the inside of fire walls for buildings of Class I, 100 feet or less in hight, or for Classes II, III and IV, 90 feet or less in hight.

SEC. 134. Skylights made at the foot of light wells or light courts shall be made either of prismatic lights set in cast-iron frames, or of glass at least ⅝ inch thick set in metallic frames; and if the latter are used, they shall be protected against injury from falling bodies by wire nettings placed at least 6 inches above the glass of such skylight and firmly and rigidly supported on iron stanchions and frame work; such netting to be made of wire not lighter than No. 8 and mesh not coarser than 1½ x 1½ inches. All other skylights shall have metallic frame, sash and curbs, glazed with glass not less than ¼ inch thick, except in the case of skylights which occur in courts or in other places below the roofs of the buildings to which they belong; such skylights shall be glazed with glass not less than ⅛ inch thick. This glass shall be protected as against breakage by wire netting placed at least 6 inches above the glass of such skylight and firmly and rigidly supported on iron stanchions and frame work, such netting to be made of wire not lighter than No. 10 and the mesh not coarser than 1½ x 1½ inches.

SEC. 135. The walls of all bay and oriel windows shall be constructed entirely of incombustible materials. The limitations of the dimensions of bay windows and position of bay windows projecting over the street line of any building shall be as follows:

1. No such bay or oriel window shall be at a less distance than 12 feet from the sidewalk grade.
2. No such bay or oriel window shall project more than 3 feet over the street line of any building.
3. No such bay or oriel window shall have a greater street frontage than 15 feet.
4. There shall not be more than one bay or oriel window for any 25 feet of frontage, and no two bay windows shall be built nearer to each other than 5 feet.

Nothing herein contained shall, however, limit the number or size of bay and oriel windows which are built in such a manner as not to project over the street line of the buildings of which they form part, but the structural parts of such bay or oriel windows shall also be made of incombustible material.

The following sections of the ordinance, while not included in the above petition, also relate to the construction of bay windows and light shafts:

SEC. 119. In all cases where the weight of floors within bay windows or abutting upon light shafts is carried on a framing independent of the inclosing walls of such bay windows or light shafts, the thickness of such walls inclosing bay windows or light shafts may be reduced; but in no case shall the thickness of such walls be less than 8 inches, nor shall any part thereof be so reduced in area that the load upon the same will be more than the maximum load hereinafter prescribed for the materials of which such walls are built.

SEC. 120. The use of hollow tile for the walls inclosing light shafts is permitted, but such inclosing walls shall be firmly anchored to the framing of each successive floor.

SEC. 121. If the walls of bay windows or of light shafts begin at any point above the foundations of the building their means of support shall consist entirely of incombustible material.

FLASHINGS.

THE CORTRIGHT METAL ROOFING COMPANY, Broad and Hamilton streets, Philadelphia, Pa., state that during the Columbian Exposition their goods will be displayed in Section H, in the Manufactures Building. The company have erected a small structure and covered the roof with Victoria shingles made of copper, while on the sides are the company's metal slates 7 x 10 inches in size.

AN OBLONG PAMPHLET, bound in firecracker paper, is the attractive illustrated catalogue and price-list issued by Thomas Lee, Cincinnati, Ohio. In presenting this annual catalogue to the trade, he announces to his patrons that he has added to his other specialties the manufacture of corrugated and plain conductor pipe, both round and square. An important feature to which he directs attention is that the area of the square conductor pipe is exactly the same as corresponding sizes in the round. On the first page are illustrations of various forms of eave troughs, the price-lists being printed in an irregular panel set in the center of the illustrations. A dozen pages are given up to different forms of gutters, the latter ones being of elaborate design. Next come cornices in the various forms in which they are made; then skylights. The division following relates to conductor pipe, round and square, corrugated and plain. At the close, attention is given to Lee's filtering joints, eave-trough hangers, ridge rolls and conductor-pipe elbows.

WE HAVE RECEIVED from W. J. Burton & Co., Detroit, Mich., a descriptive catalogue of metal shingle roofing and tiles which they manufacture. In an introductory note to the trade they say that in presenting their sixth annual catalogue they would call attention to the increased sales of their Eastlake shingles, there having been used in six years 12,434,000 square feet without a leaky roof. During the present year they have been obliged to enlarge their floor space and put in extra machinery to meet the increased demand for their goods. The catalogue, which is square in shape, contains some 30 pages, and begins with a general account of the Eastlake shingle, describing its special features and including directions for laying shingles, in connection with which cuts are presented. Following this are illustrations of a variety of styles, including the octagon fluted pattern, special valley for Eastlake and octagon, gothic tile, diamond tile and the Spanish tile. In a similar way sheet steel pressed brick is described, also ridges and finials, as well as their roll cap steel roofing. At the close are various illustrations of corrugated pipes and stamped corrugated elbows and shoes.

THE WORLD CRIMPING COMPANY of Penn Yan, N. Y., have just issued from the press a very neat catalogue and price-list of roofing, siding, ceiling and ridging, with which they are prepared to furnish the trade. The goods referred to are illustrated and accompanied by ample descriptive letterpress, which will enable the reader to understand the several merits claimed for the goods shown. Diagrams are also given, together with directions to be followed in ordering corrugated sheets. The company state that they carry in stock all gauges of these sheets from No. 16 to 27, inclusive, in 6, 7, 8, 9 and 10 foot lengths, and of a width to lap one corrugation and cover 24 inches. Brief attention is given to roofers' tools, a comparison of steel and iron roofing with other materials is made, and remarks relating to elastic roofing cement presented. The publication is bound in colored paper covers and is likely to prove an interesting addition to the trade literature bearing on roofing matters.

C. E. HOLLEY of C. E. Holley & Co., Johnson Building, Cincinnati, Ohio, and party of architects, including Col. C. S. Crockett of the United States Sub-Treasury, were taken on the 20th inst. to the quarries located at Rock Castle Springs, Ky., and operated by the company, for the purpose of inspection. Colonel Crockett went on behalf of the United States Government, with whom the company have several extensive contracts pending.

WORLD'S FAIR NOTES.

Battling with the Elements.

The work of preparing for the exposition has been a continuous battle with unpropitious circumstances. It would seem as if the elements had conspired to resist the most heroic efforts of man to complete the greatest undertaking in the history of universal expositions. There has been very little favorable weather for work of this character from the time the first sod was turned in Jackson Park. Last summer was a period of tropical storms, heavy rainfalls alternating with fierce winds, often developing into actual tornadoes, which not only checked work, but sometimes damaged what had been done and necessitated its complete reconstruction. The preceding winters had been comparatively mild, but last winter was the most severe and prolonged that was ever experienced in the Northwest. Only a few days of spring-like weather have smiled upon the workmen even in this month of April. As if to test the stability of the World's Fair structures to the utmost, a three days' storm of unusual severity raged last week. The wind blew with almost the fury of a tornado, shifting to every point of the compass during that time, apparently in search of points of weakness, while torrents of rain fell. For a few hours winter returned, with snow and freezing cold. The local signal service officer reports that at 3 a.m. Thursday the gale was blowing 72 miles an hour, and that the barometer was 28.92, the lowest Chicago has known since the office was established. When he says that the vibration of the Auditorium tower was so great that three of his observation clocks stopped running, the officials of the fair may well feel that the solidity of the fair buildings has been established. And not only did the immense structures of steel and glass stand the test, but State and foreign buildings, and even the nondescript structures on Midway Plaisance, weathered the storm. Most remarkable of all, the statuary, with a few unimportant exceptions, was not damaged. The worse feature was the renewal of leaks in the roofs, which, it had been supposed, were at last in good condition. Some of the large panes of glass in the roof of the Manufactures Building were broken by the force of the wind. This has developed a new source of anxiety, as visitors may be endangered during the fair by a similar occurrence, and the officials are now making

Plans to Catch the Glass.

Director of Works Burnham decided last Friday to let a contract for 1,045,000 square feet of wire netting to be placed under the glass roofs of four of the main buildings. By reducing square feet to acres it will be found that Mr. Burnham's contract will be equal to 24 acres. This is not regarded in the wire trade as a very large contract, however, as it will require only about 1500 rolls.

F. D. Millet, the director of decorations, has made a test of the kind of wire netting needed to protect visitors to the exposition from injury by falling glass in the roofs. The roofs are so lofty and the panes are of such weight and size that, should they strike a man's skull, they would crush it. Inasmuch as the Exposition Company cannot control the wind, Mr. Burnham decided to control the fall of glass.

The netting to be used will have a 2-inch mesh and consist of No. 18 wire. Mr. Millet stretched a sample of this size over a wooden frame and then, mounting the scaffold, let fall a piece of glass containing four square feet and sharp pointed on the netting. It dropped 12 feet and made no perceptible effect on the wire screening. Then he dropped two other pieces, also sharp pointed, without effecting any indentation. The wire netting will be placed 1 foot below the glass roofing, and Mr. Millet thinks that there will then be no possibility of accident by falling glass. The construction department has figured out that there are 47 acres of glass in the roofs of the main buildings. The wire netting, however, will not be placed under this entire surface. The roofs of four of the main buildings only will be cared for, and the following table shows the exact number of square feet which is to be protected by the netting:

Manufactures and Liberal Arts Building.

	Square feet.
Main court	295,000
Side galleries	305,000
Total	600,000

Machinery Hall.

	Square feet.
Main domes	45,000
Main clere-stories	125,000
Total	170,000

Agriculture.

	Square feet
Main building	145,000

Fine Arts Building.

	Square feet.
Central pavilion	53,000
Galleries	45,000
East and west pavilions	32,000
Total	130,000

Underneath the netting will be stretched an equal number of acres of cheesecloth to soften the direct rays of the sun and diffuse the light.

The Big Gun in Place.

On Friday the great Krupp gun was safely deposited on the carriage which it will occupy during the fair. So perfectly have the polished balls of the turntable revolved, so smoothly has every part of the Titanic apparatus done its work that not a single block of wood is disturbed in its place.

Standing with their feet deep in the moist sand of the floor, the German workmen from far off Essen saw the completion of their work. Herr Gillhausen, personal representative of the great gunmaker, looked on in triumph from his high stand on the carriage of a 75-ton giant. Back of the huge steel barrel, spotted now with the stains and rust of the long journey, lie the huge wipers and rods which are used in the loading and cleaning of the gun. Still further back on the sand lie samples of the great projectiles which this monster carries.

The carriage on which the great gun rests is built of steel, the different parts revolving on ball bearings. Cog wheels, levers and multiple chains are so arranged that it is easy work for the gunner to raise or lower, or turn in any direction the long barrel of shining steel. At the rear there are steps leading to the platform on which the gun crew is placed when the piece is in action.

Herr Krupp's agents do not hail the story that the great gun is to be presented to Chicago when the fair is over with any display of enthusiasm. If their chief has any such idea in view they know nothing of it. The specially built cars on which the monster was brought here have been switched out of the Krupp pavilion and on to the transportation tracks, where they will remain as a permanent exhibit until the fair is over. Then they will be brought into service again for the transportation of the gun back to New York, whence it will be returned to the works in Essen.

Three Men Killed While Installing Exhibits.

Three men were crushed to death while installing exhibits on the 16th. Two, James W. Warwick, a sergeant of ordnance, and Corporal M. J. Kernies, were killed by a heavy mortar gun which was being raised in front of the Government Building. The third was killed in Machinery Hall by a falling gang plank.

Warwick and Kernies were, with a number of other men, raising a 14-ton mortar to its carriage on the plaza east of the Government Building. When the mortar had been raised free from the supports upon which it rested there was a hitch of some sort and Warwick crawled under the gun to remedy the trouble. Just how the accident occurred is not known, but in some way he loosened a part of the hoisting tackle, which allowed the gun to slip from its fastenings and fall, crushing him and Kernies. Warwick's body was crushed flat and death was instantaneous. Kernies was at first not thought much hurt, but he died four hours later from internal injuries.

James Conway, check clerk in the employ of Superintendent P Healy of the installation department at Machinery Hall, together with a gang of workman under Foreman M. J. Dugan, was engaged in unloading some heavy machinery in the annex to Machinery Hall when a heavy platform or gang plank used in transferring machinery from the car fell upon Conway and crushed him.

Cunard Ship Models.

The Cunard Steamship Company's unique and historic exhibit in the department of transportation exhibits will consist of a fleet of full-rigged models showing the development and growth of this line, from the "Britannia," built in 1840 (their pioneer ship), 207 feet long, 2000 tons, 400 horse-power, down to their latest leviathan, the "Campania," the largest steamship in the world, 620 feet long, 13,000 tons and 30,000 horse-power. This is but 60 feet shorter than was the "Great Eastern." These models have been in course of construction for over a year past at the company's yards in Liverpool by their own naval architects, and are drawn on a scale of ¼ inch to the foot. The Cunard Company's joiners are now engaged in the work of installation.

The models are inclosed in handsome glass cases, and rest upon elaborately carved tables of natural oak; an ivory tablet giving full description is attached to each case. In addition to the models it is intended to display photographs of modern ships, including their latest additions, the "Campania" and "Lucania," upon screens provided for the purpose.

Veteran Engines and Coaches.

A train that is a relic of the check apron period of railroad existence arrived last week over the Pennsylvania road. The train consists of a 60-year-old engine, "John Bull," and two passenger coaches 57 years old. One of these coaches was discarded 25 years ago by the old Camden and Amboy road and purchased by a farmer at South Amboy, who took it a short distance from the rails and converted it into a chicken coop. An agent for the Pennsylvania road out hunting for relics, discovered this chicken-coop coach and purchased it for the purpose of exhibiting it at the fair. The history of the other coach is somewhat similar. It was rescued from a Jersey City lumber yard.

The train was manned by veteran railroaders. The conductor, W. T. Bailey, has been a passenger conductor since 1859. The brakemen, Jonas Hagar and Thomas Gallagher, were brakemen in 1849. The engine driver, A. S. Herbert, drove the John Bull in 1852. J. W. Sanford, the fireman, was such in 1855. Car Inspector D. H. Baker, who accompanied hem, has been foreman of the Jersey City car shops since 1849. Acting Assistant Superintend-

ent James R. Smith, who directed the running of the train, has also been a railroad man over 50 years.

The New York Central Railroad Company have completed for the fair an exact reproduction of the "De Witt Clinton," and the coaches it drew on its first trip. The original "De Witt Clinton," the first locomotive run in New York State, was built at the West Point foundry at the foot of Beech street in 1831. The coaches are diminutive affairs compared with the modern Wagner palace cars and resemble in size and shape the old-fashioned stagecoach. They are hung on immense leather straps instead of springs and when in motion rock like ships at sea.

Alongside of this train at the fair will be exhibited a modern passenger locomotive, just built to draw the Empire State express. With this will be five new Wagner palace cars. The engine, which is No. 999, was built at the New York Central shops, at West Albany, under the supervision of James Buchanan. The designer claims that the engine is capable of drawing the five coaches at a rate of speed close upon 100 miles an hour.

The old locomotives mentioned above will not be the only antiquities in the railroad line at the fair. The province of Nova Scotia will send the "Samson," an engine built in Durham, England, early in the '30s. It made its first journey on the 7-mile railroad of the Mining Association in the Pictou coal region in Nova Scotia in 1838.

The "Samson" has a triple set of driving wheels, all of the same size. The tender is in front of the engine and the fuel is fed into the furnace directly beneath the smokestack, which is the biggest thing about the old machine. The engineer sits on an elevated and uncovered platform back of the boiler, and the fireman stands on a footboard between the engine and tender.

Condition of Machinery Hall.

Just now it is a debatable question around Machinery Hall as to the condition that the display will be in at the date of pressing the button. Lieutenant Robinson, who is in charge of the building, says that they could close the doors now and place what is already on hand in position and have a better display of machinery than has ever before been attempted, and that by May 1 the display will be far beyond anything that has ever been seen in that line.

The shafting for the motive power is nearly ready, one of the four lines being fully completed and another nearly so. The other lines can be made ready in three or four days, and will easily be in working order as soon as needed. Pulleys are not yet adjusted and will not be until the machinery to be served is located, when the pulleys can be quickly placed in position where they are needed. The portion of the building which appears to be the most nearly in order is the power plant, occupying one-quarter of the floor space and filled with engines of the most approved pattern.

With the exception of one battery of Stirling boilers, the boilers are all in place and have all been steamed up. They are a formidable looking row, comparing favorably in size with a row of cottages along a village street. The appearance of the boiler room will be surprisingly neat and clean to those who are accustomed to seeing coal used for fuel in such places. The heat for these boilers will be obtained by burning crude petroleum.

Engineer Wilkinson, who has charge of the mechanical department of all that Great Britain will exhibit at the fair, has been placed at a great disadvantage by delays of the railroads in delivering his freight. For ten days the Englishmen have been waiting and saying tart things about the delay in receiving their goods, but Mr. Wilkinson is confident that by putting on a large force of men he can have his work done in time to be in order May 1. The appearance of the space devoted to the British exhibit is a bit forlorn just at present and has been commented on by those who are anxious to prove that chaos and Jackson Park will be synonymous terms on the day set for the opening of the fair, but when those exhibits do arrive there will be a tremendous lot of work done in that corner of the building, and the fact that there are 24 hours in a day and 60 minutes in each hour will be demonstrated.

The Frenchmen are also far from being ready to receive company, but they, too, think that as soon as the delays of transportation which now surround them can be overcome they will make up for lost time and report their display as being completed when the time comes for opening the fair.

Happiest of all the people whose interests are in Machinery Hall are the Germans, who are pleased to think that by the provident disposition which is a characteristic of their race, their display is now very nearly ready and they can complacently smile and say "Gesundheit."

Another nation which is slow in getting its display in position is Austria, and it is said that some of the exhibits for which space was engaged will not materialize, and that others will not arrive in time to be seen on May 1.

American exhibitors have, as a rule, made ample preparations for getting their displays in place, and many of the machines are now in position and ready for exhibition. Perhaps the most forward of the exhibits is that of the different loom manufacturers of Worcester, Mass., in which city a very large percentage of all the looms used in America is made.

Working by Night.

Electric lights, sufficient to allow the work of installation to proceed by night, have been placed in most of the great buildings. It is a matter of the utmost importance to those who are responsible for having the exposition ready on schedule time The electrical engineering department has been anxiously watched and hurried onward by those in charge of the fair, for until the lights were up nothing could be done after six o'clock toward placing exhibits and building pavilions.

The main point is the Manufactures Building. That is the largest space to be covered with exhibits and the most important to complete. The lighting of this building has been a study. It will alone contain more electric lights than the entire Paris Exposition contained.

Arc-light Engineer G. B. Foster has had charge of the work. The equipment consists of 1196 arc lights. Besides these there will be myriads of incandescent globes and innumerable lights for exhibits. The 1196 lights are for the Exposition Company and are deemed necessary for the permanent lighting of the building. This equipment is divided into 24 sections, each operated by a switch, which can be shut off and opened at will. The side aisles and outside colonnades are provided with diverging rows of 50 lamps each. The galleries are supplied in the same manner.

The main hall between the great steel trusses will contain five immense crown-shaped coronas, or "electroliers," as they are called. They are swung from the rafters and are 140 feet above the floor. Four of the huge chandeliers contain 78 lamps each, and the center one has suspended from it 102 lamps. The central electrolier will encircle the apex of the clock tower. These lamp holders are 68 feet in diameter and are constructed of steel latticed work. Each lamp is of 2000-candle power, making the lighting power of each corona equal 156,000 candles.

To supply the current for the Manufactures Building's plant requires 24 dynamos, each of 1200 horse-power. These have been put in place in Machinery Hall.

Partial light will be furnished in the Agricultural, Mines, Transportation and Machinery buildings. All these lights belong to the permanent plant. Hereafter the electrical department will put in no temporary lights, but will push forward its work of permanent lighting.

The Ferracute Machine Company of Bridgeton, N. J., have recently shipped two full carloads of machinery for their exhibit at the Columbian Exposition. This machinery consists of 12 power presses, the largest weighing about 12,000 pounds, 4 foot presses, 3 spinning lathes, polishing machinery, several smaller machines for beading, trimming, threading, &c., and about 40 pairs of dies. They have secured an excellent space, 30 x 25 feet, on the corner of two principal aisles and under one of the electric cranes, in Section 13, columns I J. 42 and 43, in the center of Machinery Hall Annex, near the large engines. This will be handsomely fitted up with a line of shafting, an engine of their own, counters, benches, an office, and with a large line of samples showing every kind of sheet-metal work. All of this machinery will be kept running with a number of operators, and several different articles will be manufactured in tin, brass, aluminum, &c., in order to show the practical working of their presses, dies, &c. They have made a contract with the Pittsburgh Reduction Company to manufacture all the articles from their metal which are made in sheet aluminum in the exposition grounds, and this in itself will be an interesting object to visitors, as aluminum is now being used for so many household articles, in addition to fancy goods, &c. Among other articles manufactured by the Ferracute Company will be pie plates, pans, skillets, drinking cups, fancy plaques, jewel boxes, napkin rings, puzzles, &c., and their exhibit will illustrate a complete metal-working establishment. Fred. F. Smith, secretary of the company, will be in charge of the exhibit, assisted by the foreman of their press shops, Edmund Hoffman, with one or two assistants from the factory and others which they will secure in Chicago. Nearly all of the machinery exhibited will be from new designs recently brought out and will show all the latest developments in sheet metal presses and dies.

Items.

The Electrical Forging Company of Boston have 1955 feet of space on the first floor of the Electrical Building at the World's Fair. They will put in a 200 horse-power heating plant driven by two 100 horse-power motors. They will exhibit an electrical cooking process and machines for rolling metals and making forgings, &c.

The Joint Committee of Ceremonies of the World's Columbian Exposition, through Secretary Culp, has notified A. J. Dowd, chairman of the Columbian Associated Travelers, that the Committee on Ceremonies has decided that there will be but one day set apart for the commercial travelers of the United States and the world. That date has been heretofore set apart by the Director General, and is July 26.

The General Electric Company have received a 25-car train, which was started from Schenectady on the 19th in charge of a special messenger. The train contains the armatures for a 1500 horse-power Edison lighting generator to furnish light for the Electricity Building, two carloads of electrical material for the electrical fountains, nine carloads of exhibits, and two of the large generators for the intramural railway. The estimated value of this consignment is $225,000.

TIN PLATES.

Irondale Rolling Mills and Tin-Plate Works.

Located at Irondale, Ohio, on the main line of the Cleveland & Pittsburgh Railroad, 55 miles from Pittsburgh, are the Irondale Rolling Mills and Tin-Plate Works of Wallace, Banfield & Co., Limited, with branch offices at 106 Third avenue, Pittsburgh, Pa. From a small beginning the plant has grown to be one of the largest and best equipped in this country for the manufacture of black sheets and tin and terne plate. The firm of Wallace, Banfield & Co., Limited, were organized in 1885, and in October of that year the new firm secured possession of the plant of the Pioneer Iron Company at Irondale, which had been in litigation from 1873 until 1885, and the name was changed to the Irondale Rolling Mills, which has been retained ever since. The plant consisted of a muck and bar mill driven by a double-balanced poppet valve engine. It was the original intention of the firm to wreck the mill and remove it to some other location. However, it was decided to keep the plant at Irondale, and the wisdom of this decision has since been fully demonstrated.

Immediately after it was decided not to remove the plant, the muck mill referred to above was dismantled and a 22 x 48 inch sheet mill was erected, the product for the first year being about 2100 tons of black sheets for galvanizing purposes. From the commencement of operations, the product of the firm was disposed of as fast as made, and for the purpose of keeping pace with their growing business a second sheet train 22 x 38 inches in size was added, increasing their capacity to about 4000 tons of black sheets per year. Upon completion of the this second train, the manufacture of fine sheet steel for stamping purposes was commenced and carried on successfully. At this time the firm decided to go into the manufacture of galvanized sheets, and for this purpose the property of the Morgan Furnace Company, consisting of casting house and about 4½ acres of ground, was purchased, the property lying just across the tracks of the Cleveland & Pittsburgh Railroad. The casting house was remodeled and necessary machinery erected, and was operated as a galvanizing department until July, 1892. However, on account of the very low prices ruling for galvanized sheets, but principally on account of the passage of the McKinley bill, the firm decided to go into the manufacture of tin and terne plate. In April, 1891, the erection of two tin mills was commenced, both mills being driven by the same engine. These mills are 23 x 32 inches, and contain three sets of cold rolls, necessary heating furnaces, pickling vats, &c. Included in the equipment was a Mesta pickling machine furnished by the Leechburg Foundry & Machine Company of Pittsburgh and six Morewood tinning pots, the first sheet being tinned on February 24, 1892.

These two tin mills were erected under the immediate supervision of William Banfield, treasurer and manager of the firm, who has been connected with the manufacture of tin plates in various capacities from his boyhood. Mr. Banfield came to America in 1872, and was employed in the first tin-plate mill built in this country, that of Rogers & Burchfield, at Leechburg, Pa. For many years Mr. Banfield made a thorough study of the manufacture of tin plate by the methods then in vogue in this country and in England, and decided that by making certain changes in the machinery much of the laborious work could be done away with, and at the same time the tonnage could be considerably increased. When the erection of the two tin mills at Irondale was begun, instead of proceeding according to methods in use in England in the equipment of tin-plate plants, some radical departures were made, by which much of the hard labor has been dispensed with and the output very largely increased.

As is well known, under the old practices it was the custom to roll down from one bar at a time, breaking down on one train and finishing on the other. This, of course, meant additional trains, and consequently increased breakage in rolls. Mr. Banfield adopted the plan of rolling down from two bars simultaneously, breaking down and finishing on the same train. In the old practice the dimensions of the rolls were as follows: Necks 14 inches in diameter, body 18 inches and length of rolls 26 inches. The rolls as erected in the original tin-plate mill at Irondale measured as follows: Diameter of necks 18 inches, body 23 inches and length 32 inches. The increased size of the rolls enabled the firm to considerably increase the output over the old method and as stated above made the work much easier for the men.

The very gratifying success met with by the firm in the manufacture of tin and terne plate, from the time operations were commenced, and the fact that their plate was being sold as fast as made, induced the firm to considerably enlarge their capacity, and in June, 1892, the two original sheet mills were changed into tin mills. The furnaces were rebuilt, rolls changed from 22 x 48 inches to 24 x 32 inches and a second Mesta pickling machine was added. When these changes were completed the output of the firm amounted to about 3000 boxes per week, of which the firm tinned about one-third, the balance being sold to other manufacturers for tinning purposes. The demand for their tin and terne plate having largely outgrown their capacity for production, the firm decided early in this year to tin their entire product of sheets, and a contract was let for the erection of two Thomas & White automatic tinning machines, which have been built in the old galvanizing department. These two machines were put in operation a few days ago and are working very successfully. The entire output, amounting to about 3000 boxes per week, is now being tinned, the firm having retired from the market as sellers of black sheets. Of this output 2500 boxes per week are bright plate of the various grades and the balance are terne plate.

In September, 1892, the frame building containing the two new tin mills was destroyed by fire and has been replaced by an enlarged iron building, built by Riter & Conley of Pittsburgh. The main building is 90 x 160 feet in size, with wing 32 x 160 feet. These two mills were idle only two weeks, that being the time required to clear the *débris* away, as the firm erected temporary sheds over the men while the new building was in course of erection. During the two weeks ending on April 8 last the output of black sheets for tinning purposes was considerably larger than the output for any previous two weeks in the history of the firm, the output for the period in question being as follows:

	Pounds.
IC sheets	446,960
IX sheets	123,650
IXX sheets	14,630
Total	585,240

A circular just issued by the firm gives a complete list of the various kinds of plates which they make, and the various uses to which they are particularly adapted. The list, as given in the circular, is as follows:

Bright Charcoal Plates

IRONDALE AAA.—A perfect plate, selected with great care; oil process; extra heavy coated; silver finish in finest quality palm oil. Packed in tissue paper. Just the plate for special work. Made to order only in 20 x 28.

IRONDALE AA.—An exceedingly fine plate; oil process; made with great care; heavily coated; fine palm oil finish; thoroughly inspected. An excellent bright charcoal plate for fine work.

IRONDALE A.—A carefully selected and very well and evenly coated bright charcoal plate. oil coated and oil finish.

IRONDALE B.—A clean, bright, finely finished charcoal plate; inspected with care. Oil finish. Unsurpassed at the price.

Coke Plates (Bright).

IRONDALE C.—A First-class coke plate; well coated; thoroughly annealed; excellent working qualities. Suitable for ordinary stamping work.

Charcoal Plates (Ternes).

IRONDALE AA.—An extra heavy coated rolled plate. Best possible that can be produced on patent rolls. Palm oil coated and oil finish; thoroughly assorted. Very soft and pliable, of exceptionally fine working quality.

IRONDALE A.—An excellent plate in every respect, equal to IRONDALE AA, except in amount of coating. Palm oil coated and oil finished.

IRONDALE B.—Working qualities equal to above; differs only in manner of coating. A good, reliable plate. Oil finish.

The shipping facilities of the firm are all that could be desired, being located on the main line of the Cleveland & Pittsburgh Railroad and only a few miles away from the main line of the Pittsburgh, Fort Wayne & Chicago and the Pittsburgh, Cincinnati, Chicago & St. Louis (Pan Handle route) Railroads, and having the same rates of freight as prevail from Pittsburgh. On one side of their plant is a switch, on which all fuel and stock is received and discharged into the works, while on the other side another switch extends to the shipping department, on which all shipping is done. Coal is used exclusively for fuel and is obtained at a very low cost, as the firm own about 720 acres of coal lands, and in addition to mining all coal needed for their mills, are extensive shippers of this fuel as well. In conclusion it can be said that Wallace, Banfield & Co., Limited, have a most complete plant in every respect for the manufacture of tin and terne plate, and

under the careful, efficient management, which prevails in every department of their business, continued success is assured. Of the many thousand of boxes of their product which have been sent to all parts of the country, not a single box has been returned to the firm on account of defective quality. The main offices are at Irondale, Ohio, with branch offices at 106 Third avenue, Pittsburgh, Pa. The officials of the firm are as follows: John C. Wallace, chairman; H. T. Duff, secretary, and William Banfield, manager and treasurer.

SCRAP.

A CURIOUS INDUSTRY is said to have lately arisen in the Punjab, India. Large quantities of kerosene are imported from Russia and America, and the tin cases containing the oil are sold cheaply when empty, and eagerly purchased by the whitesmith, who manufactures from them a number of articles, both fancy and useful, including lanterns and lamps, dispatch boxes, bird cages, watering cans, kettles, and last, but not least, jewel boxes for native ladies. Packing cases, which frequently arrive from Europe with tin linings, are also utilized in the same way.

THE FALCON TIN PLATE & SHEET IRON Company, Niles, Ohio, have been incorporated with a capital stock of $300,000. The incorporators are Warner Arms, M. I. Arms, C. D. Hine, W. P. Arms and W. D. Knowlton. The Board of Directors and officers will, it is said, be practically the same as those who have had the management of the late Falcon Iron & Nail Company. When fully completed it is reported that the company's mills will have a capacity of 10,000 tons of finished light plates and sheet iron annually. The tinning plant will probably be in operation about the middle of May.

THE AMERICAN TIN PLATE COMPANY at Elwood, Ind., are at present crowded with orders, and it has been decided to double the capacity of the plant. They are producing weekly 2000 to 2200 boxes of bright and terne plates and cannot keep pace with the demand. They are building a bar mill to make their own billets, and expect to have it in operation about May 1. The capacity of the black sheet mill will be increased from 2000 to 4000 boxes per week, so as to equal that of the tin house. They report their business as being entirely satisfactory barring lack of capacity, and no complaints have been had as to the quality of their plates.

THE WORKS of the Morewood Tin Plate Company, Elizabethport, N. J., are reported to be in full operation. The average weekly output at present reaches 3000 boxes of bright plates and 2000 boxes of ternes.

THE MILLS of the Indiana Tin Plate Mfg. Company, at Atlanta, Ind., were opened on April 5, with a capacity of 1800 boxes of tin and terne plates per week. The first shipment was made on the 21st inst., when two carloads of plates were sent to Tanner & Sullivan, Indianapolis, Ind. They are at present coating black sheets, of both home and foreign make, the construction of their rolling mill having been delayed by the recent bad weather. The sheet mill is being rapidly pushed, and will be in operation not later than July 1 next. The present capacity of the tin house will be increased to 2400 boxes per week just as soon as the pots can be added. These are being rapidly placed and will be ready in about two weeks. Atlanta is in Tipton County about four miles south of the county seat, and is at the outer edge of the strongest flow of natural gas. These works when completed will be most thoroughly equipped, and it is expected that the plates produced will rival any in the market.

BUILDING is going on actively at the large plant of E. Morewood & Co., Gas City, Ind. The tinning portion of the works is said to be well forward, and it is hoped that some of the pots will be in operation in about six weeks' time. The rolling mill plant will be installed as soon as possible.

PROSPECTS are thought to be good for the tin-plate trade this year. Although the backwardness of the season has been felt by a dull market of late, it is expected that, with the advent of settled weather and a general resumption of building operations, a large demand for roofing plates will develop during the next month or so. Indications point also to an exceptionally brisk demand for bright tin for canners' uses during the season.

A MEETING of the Tinned Plate Manufacturers' Association will take place at Pittsburgh on Tuesday, May 2, when it is expected that important questions in relation to the wages of tin-house operatives will be brought forward for consideration. Rumors are prevalent that a demand for an increase of 25 per cent. has been decided upon by the skilled workmen in tin plate factories, to take effect from July 1.

A. A. THOMSON & Co. of New York are calling attention by circulars to their Puritan roofing plates, a high grade handdipped terne, which is claimed to approximate in quality to old style imported plates. Messrs. Thomson & Co. report a very wide demand for these plates, which they are able to place on the market at the same price as Worcester grade. The firm's tinning establishment is kept in full employment in order to meet current orders.

A PROMINENT New York importer of tin plates has recently returned from a Western trip, in the course of which he visited some of the new tin-plate factories where the plates are made from start to finish, rolled and coated, by the same concern. He expresses himself as surprised at the excellence of the product he saw, both in bright and roofing plates. The domestic black sheets used he pronounces to be fully equal, if not superior, to any imported sheets he has ever seen, while the quality and coating of the finished plates compared favorably with that of the best Welsh brands. The only question in his mind is whether American manufacturers will be able to continue to afford making such a high quality of plates and selling them at present prices, even if the protective tariff were to remain intact. It is, however, beyond question that American tin-plate makers have succeeded in turning out genuine American plates which cannot be beaten by anything sent to this country from abroad.

JOHN HAMILTON of Pittsburgh, manufacturer of Hamilton's best redipped American roofing plates, recently supplied the Pittsburgh Locomotive Works, Allegheny, Pa., with 150 boxes of 20 x 28 inch plates of the above brand.

Galvanized iron is said, by the *Australasian Ironmonger*, to be in considerable demand for school buildings in the country districts of Australia where the population is not altogether fixed. Its advantages over stone and wood for this purpose have been proved by experience. Stone buildings of the cheapest kind were found very costly, the dwindling of the popula tion often leaving the stone schools a worthless asset on the hands of the Government. Wooden schools lined with wood required paint every now and then, and besides, through shrinkage of the timber, the dust, as well as hot and cold winds, entered between the boards, to the discomfort of the children. Of late years galvanized iron, whitewashed outside and lined with wood inside, has been resorted to, and it has now been found more satisfactory to use galvanized iron solely. Instead of using wood lining, 28-gauge small fluted corrugated iron is used, the building being sun-proofed internally and externally with a preparation of lime, sugar, salt and boiling water to prevent the absorption and subsequent radiation of the sun's rays. An experiment has been tried with two iron schools, one sheathed with wood and the other with iron, with the result that the former has been found to get two or three degrees warmer during the day than the iron-lined room. Besides its sanitary advantages, the cost of an iron building is considerably less than a stone or wooden structure, and if the population moves the school also can be moved without material detriment.

Employers' Association of Tin and Sheet-Iron Workers of Cook County, Ill.

The above association held a meeting at the Builders and Traders' Exchange, Chicago, Tuesday, April 18, at 2 p.m., for the purpose of effecting an organization for mutual benefit and protection. About 80 per cent. of the trade in Cook County was represented and a spirit of unanimity was shown by all present. At a previous meeting the following officers were chosen: George D. Hoffman, president; F. F. Porter, vice-president; B. F. Rubel, secretary, and A. A. Spear, treasurer. The committee appointed at previous meeting to draft constitution and by-laws reported, and after general discussion the constitution and by-laws were adopted without material change. This association proposes to treat with the Tin and Sheet-Iron Job Workers' Union as an association instead of individually, and deems it necessary to adopt this policy, owing to the fact that the union referred to has presented to the employers an agreement which in their opinion contains many arbitrary provisions to which the employers seriously object, holding that the signing of that agreement would virtually take the management of their respective businesses out of their hands. The disposition on the part of the association was one of fairness toward their employees. With the prospect of a quiet year, and a superabundance of labor, owing to the flocking to Chicago of large numbers of tinners for the purpose of working on the World's Fair buildings, this is considered a very inopportune time for the union to ask exorbitant wages. A committee appointed at a previous meeting presented articles of agreement which the employers considered just, and which it was proposed to submit to the union and the committee was continued and clothed with power to act, and also instructed to advise the union of the organization of the Employers' Association.

The International Sanitary Congress was opened at Dresden, on March 11. About 60 delegates attended its deliberations, the object of which is to determine messures for bringing into harmony the interests of international communication and to obtain mutual information as to the best methods of preserving the public health. The debates are to be kept strictly secret, and the results will not be published until the congress is closed.

On page 40 of *The Metal Worker* of April 15 was a cut illustrating the warming of a church, showing the furnace-pipe plan. The smoke pipe, as some of our readers may have noticed, was there given as 2 inches. It is hardly necessary to say that this was a mistake of the engraver. It should have been 8 inches, the size given in our correspondent's sketch.

THE RETAIL STORE.

How to Avoid the Accumulation of Dead Stock.

THIRD ARTICLE.

BY W. T. WARSOP.

Buy Lightly of goods not yet introduced, for when put in stock they may prove unsalable.

Where the price is equal, or nearly so, buy goods of established reputation in preference to those said to be just as good. Salesmen soon become tired of trying to sell the new goods and hand out the goods already introduced, leaving the others to be invoiced as dead stock at the yearly inventory.

Change Samples often, selling old ones as soon as possible; even, if necessary, make a discount to induce buying.

Buy as nearly as you can only what your trade demands, thus avoiding a surplus which is liable to become damaged or soiled. But one of the firm should buy the same kind of goods.

Display Goods, making a point to have each article kept for sale sampled. Customers will always choose clean, bright goods, leaving the soiled ones to become more unsalable.

Exercise great care in selecting goods, offering the best you can at a fair price.

Advertise specialties in your local papers, being particular to call attention to special goods.

Keep a good assortment, but do not try to keep everything called for, as that impossible and unprofitable.

Keep good help, as a good salesman will sell poor or unsalable goods better than a poor one.

Take inventory as often as once a year, noting if goods have been long on hand.

In ordering goods be explicit, thus avoiding getting goods you do not want.

When marking remnants make memorandum of size, kind or other necessary information on tag, and attach same to remnant, so that salesmen can see if it will meet the wants of customer.

When improved goods come out to take the place of others, make a price on old style that will sell them.

Before replenishing goods take a memorandum of what you have on hand, you will then know sizes or kind wanted.

Do not allow help to use new tools or other articles about the store as it injures the sale of same.

Repairs ordered but not called for or taken by customer for any reason should be tagged with name, date, size, &c., so they can readily be seen by salesmen who may offer it for sale.

Keep bargain counter for damaged articles in stock, goods to be cleaned out, or odd things disposed of. If for any reason the articles cannot be placed on counter have card printed naming article and price of same.

Damaged Goods should be put in as good order as possible and sold at less than regular price.

Seasonable goods should be displayed a little in advance of the season, thus being brought to the notice of customers.

Old stock should not be pushed back on the shelves, but should be brought to the front, making an effort to sell it first.

Goods of the same kind should be kept as near together as convenient, for if kept in several places salesmen may report none in stock, and the proprietor thinking it necessary buys more.

Don't pay too much for goods. But if you find you have done so, make a point to sell as cheaply as other dealers.

Have a regular place for surplus stock, so that when those exposed for sale are all gone salesmen will know where to look for more.

Special prices should be made on seasonable goods near the end of the season to close out.

Goods sent wrong, such as wrong in size, kind or quality, should be returned. This is better than to hold them, thinking you may sell them some time.

The Kempshall Hose Mender.

Underhill, Clinch & Co., 94 Chambers street, New York, as agents for the E. Kempshall Company, New Britain, Conn., are introducing the mender illustrated in Fig. 1. It is made of refined malleable iron, and in use requires no straps. It is simply screwed into the hose, and the levers hammered down, as in Fig. 2. The manufacturers claim that they will never work loose.

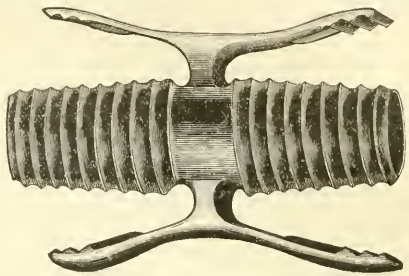

Fig. 1.—The Kempshall Hose Mender.

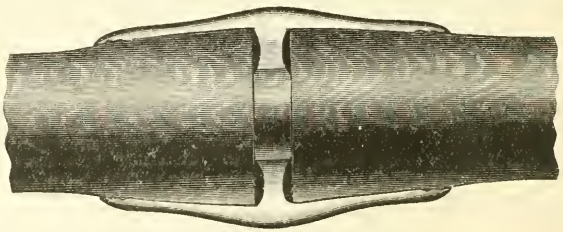

Fig. 2.—The Kempshall Mender Applied.

MEMORANDA.

EDWARD AUSTERMUHL, a stove dealer and tinner at 525 Market street, Camden, N. J., who resides in one of its suburbs, has been elected as a school trustee for the Rosendal district to serve three years. An appropriation of $6500 has been made for the use of the schools. This is an evidence that these people knew in which trade to find a man to look after drafts and stop leaks.

WILLIAM H. TEFFT, formerly of Saratoga, N. Y., died at Denver, Col., April 18, aged 30 years, of consumption. For several years he was employed in the hardware store of William Waterbury at Saratoga. He was an Odd Fellow and a Mason.

THOMAS COFFIN died at Brooklyn recently, aged about 80 years. He was one of the old business men of Poughkeepsie, N. Y. Having been a member of the firm of A. J. Coffin & Co., stove dealers, who kept on Main street, that city. He was at one time a member of the board of trustees and was also a member of the Board of Aldermen in the early days of the city. His business history was associated with the early days of Poughkeepsie.

THE HARDWARE STORE on East Water street, Elmira, N. Y., formerly conducted by C. W. Young & Co., is now under the management of John E. Stowell & Co. The business has been established 25 years, and the new management will undoubtedly continue it successfully. Mr. Stowell is of the firm of Babcock & Stowell of Binghamton, N. Y. W. P. Chase will manage the Elmira house.

The new annual Tax Rate bill in New York State fixes the rate at 2.24⅜. Last year the tax rate was 1.98.

Sultana Sad Iron.

William Vogel & Bros., selling agents for H. Clayton & Co., 37–47 South Ninth street, Brooklyn, N. Y., are offering the sad iron shown herewith. In Fig. 1 the iron, with stand, is illustrated, and in Fig. 2 the operation of heating the iron by alcohol. The top of the iron is provided with indestructible packing, which in operation is saturated with alcohol, lit, and the top turned down. The top and bottom of the iron are fastened together by turning the thumb-piece near the front of the iron, and the flame striking against the bottom heats the iron for use. The stand is so arranged that when placed in position, as shown in Fig. 2, with the handle, they form a three-legged base to hold the iron in position while being supplied with alcohol and being lit. The openings around the sides of the iron provide ventilation for the flame. The iron is also provided with an opening at the back suitable for admitting a gas jet, and gas may be used for heating the iron in place of alcohol. The iron is nickel plated and may be heated, the makers claim, in either way in from seven to ten minutes. They also state that the iron is perfectly safe.

What Retailers Say in Regard to Sales to Their Customers by Manufacturers and Jobbers.

The articles which we have published in regard to the manner in which manufacturers and jobbers encroach upon the legitimate trade of retail merchants have attracted a good deal of attention and called out many responses from the trade. Some of the prominent jobbing houses express their gratification that the matter has been taken up by members of the retail trade, and allude to the question thus brought up as rapidly becoming a very serious one, not only to retail Hardware merchants, but also to jobbers. They specify cases in which manufacturers in certain lines sell to jobbers at fixed prices, and bind them by agreement to sell at other fixed prices to their customers. It is stated that then the manufacturers accept orders from large grange supply houses and sell to them at a rate which enables them to retail the goods at relatively low figures.

In the letters which are given below it will be observed that our correspondents refer to the condition of things as seen from their standpoint. It will be seen that reference is made to the fact that the trouble in question is not confined to the manufacturers, but that in some cases jobbing houses are referred to as dealing with consumers in a way that is troublesome to the retail merchants. The whole question is one of very considerable interest and apparently of growing importance as there appears to be an increasing tendency in the direction of transactions between consumers and both manufacturers and jobbers. We invite a thorough discussion of the question in its different aspects, and shall be glad to hear from any of our readers in regard to the matter. The letters printed below are written from the retailer's point of view. There is obviously something to be said also in regard to the interests of jobbers and manufacturers in the matter. In the letters we omit the names of our correspondents and indicate simply the State in which they are located:

ILLINOIS.—We have trouble with the jobbers in the West, especially with the Gun, Ammunition and Binding Twine trade, and this has gone to such an extent that the Gun trade is nearly ruined. We have had no difficulty so far with manufacturers.

GEORGIA.—We are annoyed and lose considerable trade by both manufacturers and jobbers selling direct to consumers, especially the jobbers, and this practice we are sorry to say is on the increase.

ALABAMA.—We have felt some inconvenience from this practice. Both jobbers and manufacturers put men in our territory and sell to the trade that by right belongs to us. We trust you may be successful in overcoming this practice to a certain extent if not entirely.

ILLINOIS.—We lose some trade by jobbers and manufacturers pricing and selling to our best contractors. The most of our trouble is with jobbers from the small cities like Peoria, Quincy and Burlington. We are continually having their prices quoted to us by contractors and it seems to be growing every year. These small jobbers claim that they should have some of the trade and if they cannot get it through the merchant they must go to the contractor or consumer. The contractor will go to these jobbers and buy a bill and pay spot cash for it and then ask us to duplicate it and wait for payment until the job is done, or from three to six months.

ALABAMA.—We are troubled to some extent with jobbers, some of the smaller of whom visit our blacksmiths and a few of the factories.

ARKANSAS.—There is a great amount of business that is done direct with the jobber, and the worst feature of the matter is that their trade is of course all cash, while all of the time trading is done with the home dealer. We do not patronize a jobber who sells direct, if we know it, and think all other business men should do the same.

ILLINOIS.—There is a tendency in the direction of manufacturers and jobbers selling to consumers in their territory, both from Chicago and St. Louis, but the retail dealer appears to have no redress in the matter.

ARKANSAS.—We are annoyed considerably by jobbers selling in our territory to consumers.

INDIANA.—With some of our customers manufacturers and jobbers are our worst competitors. The jobbers in our neighboring city will solicit our trade at a named price and then turn around and sell to our customers at the same price. We have some customers that from three to five years ago we sold, say, from $50 to $150 worth of goods a month, who today buy only $10 to $20 worth of goods a month. It is a question with the retailers here as to what will be the outcome of it all unless we retire from the field and leave it to the jobber. We think that this tendency to deal with consumers is growing and will soon have to be met by some means, for we do not think the consumer can do without the retailer.

CONNECTICUT.—We see a growing tendency on the part of both manufacturer and jobbers of going to the consuming trade in our vicinity, and we are sorry to see some of the large manufacturers of New Britain coming here and selling, if at all possible, to the manufacturers, sending one drummer to the factories and another to the Hardware trade.

DELAWARE.—We consider the complaints referred to as likely well founded, and that circumstances here would justify a similar statement, though we would not specify cases or enter into particulars.

ILLINOIS.—There seems to be an increasing tendency in this direction. Especially is it the case with jobbers. It interferes with my trade to a considerable extent, besides being a great deal of annoyance.

CONNECTICUT.—We are more or less annoyed by manufacturers quoting prices and selling goods direct to our customers, as is probably the case with every wholesale house. In some lines of goods we think the manufacturers are pushing for the smaller trade, but generally we find very little difference as regards our trade.

DELAWARE.—The trade has suffered annoyance and very great loss by the practice of manufacturers and large jobbers in catering directly to the consumers. The epidemic of pool and trust organizations which has been prevalent during the past three or four years, we think, has been the chief cause of bringing the manufacturer and consumers together. For example: The manufacturers of a certain line of goods would organize and agree to the same price, without regard to the quality of the goods, thus, of course, obliging the middleman to buy the best quality, and the manufacturer of the poor quality, not being able to move his goods through the jobber, was driven to sell directly to the consumer, and the consequence was that soon all manufacturers were obliged, for their own protection, to work directly with the consumer.

Another very serious cause has been the matter of urging sales by dating the invoice from one to three months after the shipment of the goods.

The grestest injustice of this system is shown in the fact that we are obliged to carry a large stock and meet the low prices named our trade by the manufacturers, sell in small quantities at these cut prices and take notes in settlenent, renewing them from time to time, while the manufacturer sells our trade for cash and in large quantities, leaving the paper here and sending the cash away.

We believe that if there is not a change made that eventually the manufacturer will have to add another department to his business—that of jobbing.

ALABAMA.—We have noticed a growing tendency in this direction, but it is hard to estimate amount of damage done. We, of course, do not suffer as much as those of the trade located near the manufacturing centers.

INDIANA.—Of late we have been bothered more or less with manufacturers, and especially jobbers, selling to consumers in this part of the State. This is done more particularly in Barb Wire and Merchant Iron.

FLORIDA.—The practice of manufacturers selling their goods direct to the consumer is in our case probably a matter of greater annoyance than any one else in the country. We are situated in a section of the country that is a great resort for overworked and elderly people and many of the manufacturers who come during the winter in search of rest and health endeavor to unload a sufficient quantity of goods to make expenses; this they generally do at a less price than we would care to sell, which has the tendency of fixing the price for future transactions. We think it is an evil which if properly called to the minds of the manufacturers would be very quickly remedied.

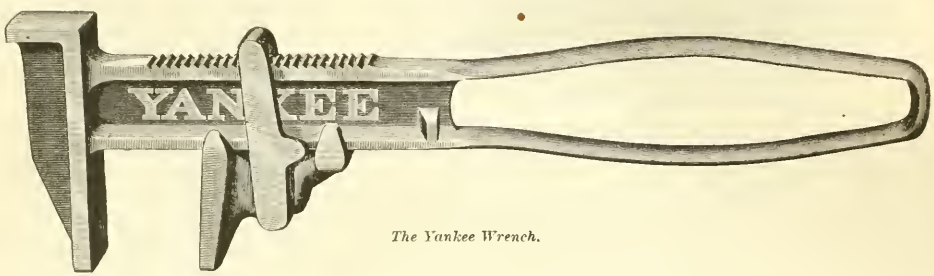
INDIANA.—We have been very much annoyed by the practice of manufacturers and jobbers selling to our trade, and ever since the F. M. B. Association was organized in our State the tendency has been more in that direction. Feeling ourselves unable to do anything to counteract it we have patiently endured.

ILLINOIS.—We have found an increasing tendency in this direction. We have had several very extraordinary instances of jobbers selling direct to consumers. One we have in mind is that of a large Paint firm of Chicago going to the trouble of hiring a team and going ont in the country to sell a job of Paint. But we beat them by selling at their prices, or cost to us. In some lines we think that the fault is in the retailers forcing them to sell so cheap that they have to sell wherever they possibly can, making them a larger aggregate of sales.

If there was concerted action taken on the part of the retailer and jobber to stop the manufacturer from selling direct to the consumer, it would probably stop the jobber from doing the same thing.

CONNECTICUT. — We are annoyed by manufacturers and jobbers (particularly the latter) quoting consumers lower prices than to the dealer. Many consumers do not fully appreciate the retailer carrying a stock to order from when needed, but will buy of agents or direct from the manufacturers, many times paying more for goods than the regular retail prices.

ALABAMA.—Regarding the practice of manufacturers and jobbers selling goods to consumers, the only trouble we have had in this direction is with jobbers of Firearms and Sporting Goods in St. Louis and Philadelphia—St. Louis more especially. There is a certain large jobbing house there in this line that regularly send circulars with their lowest prices to men, women and children all over the country regardless of their "race, color or previous condition." All such firms should be systematically boycotted by the trade.



The Yankee Wrench.

The Yankee Wrench.

The Gwinner Mfg. Company, Hamilton, Ohio, for whom Harmon & Dixon, New York, are agents, are offering the above wrench as shown herewith. The wrench is 9 inches long, weighs 12 ounces and is made entirely of malleable iron. In adjusting it the lower jaw is slipped along to the required position, when the yoke drops into one of the notches at the top, holding it firmly in place. It is quickly adjusted and, the manufacturers claim, never slips.

Two large deposits of nickel have been discovered in the Kootamie district of British Columbia, easily accessible, but the ore has not yet been assayed, and it is not known if it can be worked at a profit.

STOVE TRADE NOTES.

The Stove Manufacturers' Convention.

Preparatory to the annual convention of the stove manufacturers, to be held the end of next month in Chicago, the secretary, D. M. Thomas, issues from his office, 80 Broadway, New York City, under date of April 24, a series of circular letters to the Manufacturers' Association, the Defense Association and other stove makers. The following letter is addressed to the members of the National Association of Stove Manufacturers:

The twenty-second annual convention of the above association will be held at the Palmer House, Chicago, on Wednesday, May 31, 1893. Proceedings will commence at 10:30 a. m. sharp. The change has been made from Detroit to Chicago in accordance with the authority given to the Central Executive Bureau. The president trusts that every member will be present, and as he has given a general invitation to all stove manufacturers, he hopes that you will make it your business to see that his invitation is widely accepted, and bring your neighbors with you. Efforts have been made and will be made to provide such a programme as will be interesting, instructive and profitable. Subjects will be considered that concern every stove founder alike. Please advise me of your intention of being represented by filling out and returning the inclosed form. Firms wishing to be represented by employees, must furnish them with credentials addressed to me.

The next letter is the announcement of the annual meeting sent to the members of the Stove Founders' National Defense Association:

The eighth annual meeting of the Stove Founders' National Defense Association will be held at the Palmer House, Chicago, on Tuesday, May 30th next. Proceedings will commence at 1.30 p. m. sharp. The president hopes that each member will be present without fail. If there are any stove founders who would be desirable members that are not now on our rolls, it would be well that they should be influenced to send their application to me at least two weeks before the meeting. Please inform me of your intention of being present by filling out and returning the inclosed blank.

The third communication, which we print below, is a general invitation addressed to stove manufacturers, that they will attend the coming convention:

The twenty-second annual meeting of the National Association of Stove Manufacturers will be held at the Palmer House, Chicago, Wednesday and Thursday, May 31 and June 1 next. The president instructs me to give you as non-members a most cordial invitation to attend and participate in our deliberations. We shall be glad of such advice and information on all subjects discussed as you may seem fit to impart. Strong efforts are being made to prepare such a programme for the convention as will render it profitable to all in attendance. As the Columbian Exposition will then be in full blast and there will be no better time to visit it your attendance in Chicago will be most opportune. It will afford me pleasure to engage hotel accommodation for you on the same terms as made for our members, particulars of which will be found in the inclosed circular. Please advise me promptly of your intention of being present by filling out and returning the inclosed form.

Those who are concerned as to the accommodation that will be offered at Chicago at the time of the convention, will be interested in the following letter from Secretary Thomas, addressed to stove manufacturers:

The Palmer House Company have agreed to reserve rooms for attendants at our Convention at their usual rates, which are,

For rooms without bath, with meals, $3.50 per day.

For rooms without bath, without meals, $2.00 per day.

For rooms with bath and meals, $4.50 per day.

For rooms with bath, without meals, $3.00 per day.

And upward, in each case according to size and location of room. As the Columbian Exposition will cause the Chicago hotels to be all crowded with guests at the time of the convention, and the Palmer House perhaps most so, the proprietors ask that such of our members as are sufficiently intimate with each other to do so will occupy rooms jointly, so that by placing two beds in a room their power to accommodate the general public will be correspondingly increased. They do not stipulate for this in their agreement with me, but simply ask it, when unobjectionable, as a matter of convenience. To insure satisfactory accommodation, it will be necessary that immediately on receipt of this you inform me how many and what price rooms you require, how many will be in your party, and from and to what date you require the rooms. For parties who make application on the inclosed form I will engage such accommodation as they desire. Application may be made direct to the Palmer House Company, but our members will probably be better served, if made through me. Do not delay application. I cannot guarantee good service much later than May 1.

Our readers have been informed of the action taken at the conference between the committees of the Stove Founders' National Defense Association and the Iron Molders' Union, at which an advance of wages was requested and refused. The following letter from Secretary Thomas, addressed to all stove founders, will be read with interest in this connection:

I am instructed by the president of the Stove Founders' National Defense Association to inform you that at the recent conference between the committees of that organization and of the Iron Molders' Union, to consider the request for an advance of 15 per cent. in wages, the molders' representatives declined to take "no" for an answer, and it was determined to give their committee an opportunity to appeal in person to the stove manufacturers at large on the occasion of the annual conventions of the two national associations, which occur May 30, 31 and June 1 next. You are therefore invited to attend a special meeting of stove manufacturers, to be held at the Palmer House, Chicago, at 10 o'clock on the morning of Thursday, June 1, at which the matter of an increase of wages will be considered, and, if possible, finally decided. The officers of the Molders' Union will be present. This is an occasion of great importance to you personally. The demand is made and insisted upon. No decision that is not concurred in by the whole trade will be satisfactory. You are earnestly requested to be present and lend the weight of your influence to the verdict, whatever it be. Please advise me on the inclosed form of your intention to be present.

Accompanying these letters Mr. Thomas has sent out blanks to be filled out by those who propose to attend the convention of manufacturers or the meeting of the Defense Association. There is likewise a blank on which to make request for hotel accommodation.

The Milwaukee Gas Stove Company.

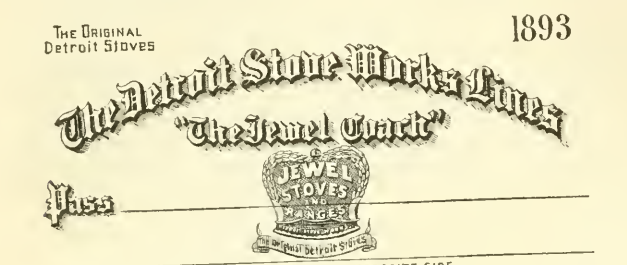
The new catalogue of the Milwaukee Gas Stove Company of Milwaukee, Wis., is a handsome publication of 26 pages. Special care has been taken in its preparation. The cuts are of a high order of excellence, and all other details indicate perfect taste in catalogue work. The goods made by this company are all put on the market under the brand Perfection. The burner used is of a distinctive type peculiar to this company. Large sizes for top cooking are made in the shape of a seven-pointed star, in the arms of which there are holes drilled for the passage of gas. An ingenious cleaning device is a permanent fixture. This consists of a light frame running under each arm of the burner, with a needle projecting upward under each hole. A lever projecting a short distance outside the stove operates all the needles simultaneously, forcing them up through the holes. The oven burners are telescopic, being so constructed that they can be drawn out of the stove to be lighted and then pushed back in place, thus doing away with the necessity of the operator stooping and also avoiding all danger of explosions from gas suddenly filling the oven. Special burners for ironing are 6 inches long and of oblong form, while small ones are provided for simmering. The Perfection valve has a double gas way. One is operated by a small wheel and regulates the amount of gas passing, in the usual way, while the other is controlled by a set screw, which permanently regulates the supply of gas according to its pressure. This peculiar construction enables the valve to be used for either natural or artificial gas.

The largest sized Perfection range is a six hole range 35 inches high, with a top-plate 50 by 30 inches and four compartments. One of these is for baking and roasting, one for broiling, one for warm-

ing and one for the water heater. The ovens are very large, and the broiler is on the same level as the baking oven. Much attention has been given to the design of this range, to secure a fine appearance as well as perfect adaptation to the purposes sought. All parts are made on the interchangeable plan. The weight of this range, crated, is 600 pounds. It can be used for natural, artificial or gasoline gas, and is furnished with or without the water heater. The water heater is of special construction, which is worthy of note. It consists of coils made of heavy drawn copper tubing, which are tested to 75 pounds steam and 200 pounds cold water pressure. Being made of copper, which is the best conductor of heat, and having an even thickness throughout, the manufacturers claim superior advantages for this heater. The next size is also a 6-hole range, but the top is 40 by 25 inches. The next has a top also 40 by 25 inches, but differs in having four cooking holes. Another class of ranges has tops 43 by 24 inches, four cooking holes, two compartments only (one for baking or roasting and one for broiling) and the water heater on a bracket at the side with two holes over it which can be used for cooking while water is being heated. Another 4-hole range has a top 33 by 23 inches. A still smaller range has three holes and a top 33 by 24 inches. A new 4-hole range, 40 by 24 inches, which has just been brought out, is of a very handsome pattern, the cast front, doors and base being molded in artistic designs of scroll and fluted work. The Perfection water heater is for independent water heating, cylindrical in form, 20 inches high, and fitted with a telescopic burner, which can be pulled out, lighted and pushed back in place. A line of Perfection gas heaters is made in three styles, one being cylindrical with round reflectors, the second also cylindrical with asbestos fronts and the third square with either reflectors or asbestos fronts. The company also manufacture hot plates or portable stoves with one to three burners, small single burner stove, tailors' iron heaters, soldering furnaces, coffee roasters, candy heaters for manufacturing candy and gas kilns for firing china and glass.

Pass for the Jewel Tally-Ho Coach.

In our issue of last week we called attention to the invitation extended to the friends of the Detroit Stove Works to ride on the Jewel tally-ho coach, which it is proposed to run between the Chicago headquarters of the company, on South Canal street, and the World's Fair grounds. In connection with each invitation is a pass which entitles the holder to transportation on the coach during the progress of the Columbian Exposition, provided it is first duly presented for registry at the Chicago headquarters of the company and countersigned by the second vice-president. A *fac-simile* of the front of this pass is presented in the accompanying engraving, the opposite side carrying a list of officers of the company, and the statement that the pass is not transferable, but will be honored upon compliance with the conditions above stated.



Fac-Simile of Front of Pass for Jewel Tally-Ho Coach.

directly over the center of the furnace and the hottest portion of the fire, thus warming the air with great rapidity and economy.

J. M. Kelly, secretary and treasurer of the Lexington Foundry Company of Lexington, Ky., has invented a detachable sheet-steel oven, which is to be employed in connection with the stoves turned out by the company named. Among the advantages claimed for this form of construction is the uniformity of thickness of the material, which renders baking more satisfactory, its durability and the saving of fuel. The oven is furnished with cast braces under the front of the plates, while stay bolts extend vertically through the lug on the bottom strips and thence through the extreme bottom, thus securing it against buckling or warping. By the simple removal of the thumb screw from a horizontal rod, which extends through the opposite side, and unscrewing the nuts from the stay bolts, the oven can be taken out entire, thus admitting of the cleaning of the interior, or the repairing of any portion of it. At present the ovens are being made of No. 16 gauge metal, although heavier can be substituted when so required. It is also claimed that it is unnecessary to alter any patterns in order to adapt the oven to use. We understand that the Lexington Foundry Company have completed arrangements for the exclusive manufacture of stoves with this feature, intended for the South and Southwest, as well as such other territory as they may see fit to cover. The company are daily receiving orders for stoves embodying this feature and which are sold at a slight advance over the price of those carrying the old style of cast oven.

ODD PLATES.

The Fox Furnace Company, 28 Vincent street, Cleveland, Ohio, send us a circular showing a broken view of the Fox furnace which they manufacture. We understand that this construction is the result of many years' experience in this line of business and combines, it is claimed, the vital points of "great economy and capacity, durability and simplicity." The furnace is provided with triangular bar grate, heavy double corrugated fire pot, dust flue, double casing and steel plate radiator. There is a series of air tubes which conduct the air to be warmed

William Dengel of Salina, Kan. has recently brought to the attention of the trade a stove designed for cooking and heating purposes and embodying several features of novelty. The idea is so to place the stove that it will occupy a portion of two rooms and be so constructed that it can be operated from either or both apartments, as circumstances may require. It is provided with the usual boiler holes, ovens, hot-water reservoir, &c. The work of attending to the fire, cleaning out the soot from the hot air passages, removing the ashes, &c., is intended to be done from that portion of the stove which projects into the kitchen. The other portion of the stove is adapted for the removal of cooked foods ready for the table, the rewarming of different foods, as desired, and the heating of the room in which that portion of the stove projects.

The Huette-Barler Mfg. Company, 111 and 113 Lake street, Chicago, send us samples of circulars which they are now distributing. They comprise a four-page illustrated treatise on the Ideal oil heater, a four-page collection of testimonials, a leaflet on the Ideal roller base for the heater, a circular describing Barler's shine cabinet for a shoe-blacking outfit, and a colored picture of Horticultural Building at the fair, with an advertisement of the shine cabinet on the reverse side.

The Bennett & Peck Company, Cincinnati, Ohio, have been awarded a contract for the heating and ventilating and dry closets for the new school building at Sewyckley, one of the suburbs of Pittsburgh.

It having been learned that the family of M. P. Low were in straitened circumstances, Walter Slade of the Barstow Stove Company very efficiently undertook the raising of a subscription for their benefit. He canvassed the trade, and, being very kindly received, a substantial proof of their appreciation of his efforts was tendered him. Mr. Slade is an indefatigable worker in any undertaking he enters, and in this instance raised about $300. On behalf of the family he tenders to the trade and friends generally their sincere and heartfelt thanks for their kindness.

The Marion Stove Company, at Marion, Ind., report an active demand for their Retort stove, which has been improved for the 1893 trade. They now make this stove to the exclusion of all others. They make also a full line of hollow ware.

What is known as an air pump attachment for cook stoves and furnaces has been patented by George Samuel Boyler and Frederick Rothwell, Havelock, Canada. The object of the invention is to provide a cheap and simple means for feeding a continuous blast of air to the fire box when the fire is started so as to promote combustion. This object is accomplished by placing under the hearth in a horizontal position a compressed-air reservoir leading from which to the fire box or fuel chamber is a feed pipe. The arrangement is such that the compressed air is forced into the fuel chamber of the stove, suitable means being provided for replenishing the reservoir as circumstances may require. A stop cock is provided for controlling the flow of air from the reservoir to the fuel chamber.

The Excelsior Steel Furnace Company, 110–114 South Jefferson street, Chicago, have taken advantage of the dull season just closing to thoroughly overhaul and enlarge their manufacturing plant, taking out much of their old machinery

and substituting new and faster machines wherever possible, and, as a result, they have fully doubled their capacity. All machinery in their factory has either been built by them or after designs furnished by them, and the only exception to this is the new lock-seaming press which they have just received from the E. W. Bliss Company, Limited, of Brooklyn, N. Y., which is a special press recently added to the Bliss line, the one sent the Excelsior Company being the first, it is understood, to be sent West. In response to a demand from the trade for a convenient order sheet, price-list and descriptive circular combined, the company have just issued a four-page circular, on the first and second pages of which they illustrate their furnace fittings and specialties. The third and fourth pages give full lists of these fittings, every size included, with blank spaces in which to fill the quantities ordered. Prices are also attached in connection with every size. The whole arrangement is exceedingly convenient for the company's customers.

THE TROY OIL STOVE COMPANY of Troy, N. Y., are directing the attention of the trade, by means of illustrated circulars, to the Genuine Beauty oil stove, which they state can be procured from H. Rendtorff & Co., Chicago, Ill.; F. M. Borden & Co., Philadelphia; C. B. Corby, 117 Beekman street, New York; H. T. Whitten, Boston, and B. C. Bibb Stove Company, Baltimore. In directing the attention of the trade to this stove, the makers state that the great success which the Beauty has met in years past has this season induced several so-called manufacturers to put on the market a stove so nearly like the company's No. 12 that they are compelled to think one of the stoves has been filed up for patterns. They therefore caution all dealers to examine carefully all new stoves before purchasing. The Troy Oil Stove Company state that they have good valid patents on their stoves, particularly the hinge upon which the body swings, and that they will make every effort to protect their rights.

THE ART STOVE COMPANY of Detroit, Mich., have just issued a catalogue relating to the Laurel oil heaters, adapted to the season of 1893. These goods are illustrated and carefully described, the principal features being referred to in a manner calculated to interest the trade. The Laurel heaters, we understand, have met with a very gratifying success during the past year, and the demand for them in the present season is far in excess of that experienced in 1892. The company attribute this fact to the beauty of the design of the 1893 goods and to their superior construction.

AN APPARATUS for heating and ventilating rooms is the subject of a patent granted on April 18 to William H. Stiverson of Brookline, Mass. The device is intended to be placed next to the window or other opening, and in operation it introduces the warmed pure air from outside into the room without interfering with the use of the window. At the same time the inventor claims the foul air is conducted from the floor of the room together with the products of combustion to the outside. By means of the arrangement employed it is claimed that the air in the room is not vitiated, and at the same time that fresh air is being taken into the room the foul air is being discharged from it. Among the advantages to which reference is made are quickness of operation, cheapness of construction and the large amount of heat thrown out.

THE SYRACUSE STOVE WORKS, Syracuse, N. Y., state that the production of Welcome stoves and ranges for the first three months of the year was more than double that of the corresponding period of last year. They report the outlook for 1893 as very encouraging, and suggest to intending purchasers the wisdom of placing orders early, so that shipments can be promptly made and disappointment avoided when the fall trade opens. The company state that on their Model and Magic Welcome six and four hole ranges they are behindhand with their orders, while the demand for parlor stoves, including those for burning wood as well as those for coal, is greater than ever before at this season of the year.

UNDER THE EFFICIENT MANAGEMENT of Samuel E. Dickinson the trade of the Lehigh Stove & Mfg. Company of Lehighton, Pa., has grown until a new addition to the foundry 64 x 74 feet has been erected to meet the requirements of their business. The improvements will be completed, it is now hoped, by the middle of May. Late productions which have been favored by the trade are the 5 hole range Gem Lehigh, which appears in a new dress, and the handsome square range known as the Valley Lehigh. The latter has high shelf, skirting and reservoir when desired; ventilated oven, pedal door opener, and an excellent duplex grate. The design, mounting and trimmings make it first-class in appearance and quality. A pertinent sentence in their circular lithographed in colors with the Lehigh trade mark prominent, says: "The dampers and flues being the same as in our Popular Lehigh guarantees the operation."

THE BUSSEY & MCLEOD STOVE COMPANY of Troy, N. Y., in conjunction with the Chicago Stove Works of Chicago will make an interesting display of Gold Coin stoves at the World's Columbian Exposition. The demand for space in the Manufactures Building is said to have been so large that the amount allotted to each exhibitor has consequently been small. In fact, the company state it is too small to show anything but sample stoves. The company, therefore, extend to all patrons and friends who may visit the city a most cordial and urgent invitation to inspect their display and visit the Chicago office and salesroom at the corner of Blue Island avenue and Twenty-second street. In this connection the company state that the electric street railroad company have just completed the Hoosick street extension, by which passengers are now landed within a few feet of their foundry in Troy, N. Y.

THE HOWARD FURNACE COMPANY have removed their New York branch, of which W. B. Wilkinson is manager, to 210 Water street, near Fulton street, where they have increased sample and office room. The company show a new line of single radiator furnaces, comprising fifteen sizes of hot air and ten sizes of combination hot water and hot air. They also have storage and shipping facilities for carrying a full stock of castings, casings, registers, fittings, repairs, &c.

THE TAYLOR & BOGGIS FOUNDRY COMPANY, Cleveland, Ohio, are the assignees of a patent recently granted to William H. Clemes for a combined wick tube and burner plate for oil stoves. The device is formed of one piece of stamped sheet metal, is of simple construction and can, it is claimed, be manufactured at a comparatively low price.

JAMES LAMB of Detroit, Mich., has patented a heating stove in which the air may be conducted through a central portion, above the fire, whereby the rising hydrogen gases from the burning fuel may be thoroughly mixed and a more perfect combustion obtained than results in stoves as ordinarily constructed. The invention consists of an annular chamber arranged close to the mouth of the feeder, or forming a part of it, and provided with one or more air supply pipes, arranged to receive the air from the room through the walls of the stove. The annular chamber is provided with jets for discharging the air toward the burning fuel for the purpose of promoting combustion.

PERHAPS it may sound funny to those uninitiated, says a correspondent, but I saw two of the prominent officers of a big stove company the other day baking bread and potatoes with all the anxiety of a model housewife. It was in the test room of the stove plant. This test room is a prominent feature of some manufactories where stoves are made. It is the practice nowadays to give heating goods a severe experimental trial and discover, if possible, any deficiencies of the article before it begins its career as a public servant. One of the above-mentioned stove company officials had his watch in hand and the other paced up and down nervously, examining now and then the fire, the drafts and all of the salient points. Just as 20 minutes was up the oven door was flung open and a sweet-smelling loaf of bread pulled therefrom. It was examined most carefully. A wire penetrated its interior to see if it were done evenly and all through. Every side of it was scanned with as much care as the *chef* of a big hotel examines the products of the *cuisine* which are to feed his particular guests. The stove company officials smiled at the result and seemed highly pleased. The bread was undoubtedly good, a novice could tell that. I verily believe that, had the stove not been hot, they would have patted it in commendation of its baking powers. And in a book of tests the details of the operation were put down with great care. Surely, stove making to-day is a great science.

AMONG the recent improvements made at the plant of the Perry Stove Company, Albany, N. Y., is the addition of a small dynamo to furnish 25 lights and a donkey engine to run part of the machinery. These have been put in by the company for night work, as they are obliged to operate until 9 or 10 p.m. to keep abreast of orders.

A NEW RANGE has been got out by the Perry Stove Company, and is known as the Glen Argand. It is a four-hole stove, has nickel trimmings and numerous practical features, and comes in four sizes. It can be had with or without reservoir, pipe shelf, &c.

JAMES BOYLE & Co. of Salem, Ohio, are getting out for the fall trade a neat heating stove, in four sizes, which will be known as the Perfect Oak. The second stove which they mounted was teated, a fire being built on a perfectly clean grate, which was heated until red hot. The fire was then covered and kept, we understand, for 47 hours, all with 24 pounds of coal and 15 pounds of slack, the coal used in starting the fire being included in the 24 pounds. The new stove is provided with all the modern improvements, having cone grate, double fire pot, wedge draft slides, lap joints and handsome ornamentation, in which is involved the use of more or less nickel work. One of the features to which special attention is invited is the solid ash pit and large ash pan. The company state that the stove is first class in every respect, and are confident they will sell all their foundry can produce.

SOMERSWORTH MACHINE COMPANY with plants at Dover, Great Falls and Salmon Falls, N. H., and employing a force of 300 men, are producing a large number of stoves annually which are sold principally in New England, although the business is by no means confined to that section. The company are preparing to push the Somersworth Prize parlor stove, which, it is claimed, has a flue arrangement different

from any other. It is made with two Russia iron back pipes, connecting the base with a cast-iron damper-box. When the damper is closed the heat passes down one pipe, entirely around the base, then up the second pipe to the chimney. Cold air is admitted through an opening in the base and by this means perfect ventilation as well as uniform heat is secured by circulation. Another feature is a patent damper which is designed to avoid all danger from ignited gas, the expansion of which will instantly open the damper and allow the gas to escape up the chimney, which being accomplished, the damper closes automatically. A full line of parlor stoves and ranges is made by this concern; also sinks, lawn vases, door hangers and hollow ware. The business is under the management of E. H. Gilman.

FRANK A. MAGEE of the Magee Furnace Company of Chelsea, Mass., has recently been granted a patent for an improvement in cook stove construction. Heretofore the Magee stove has been provided with a grate of peculiar construction, the same comprising two horizontal shafts parallel to the frame, geared together at one end, and having short curved, laterally extending grate bar sections. The shafts are carried by the frame, which has formed an integral part of the stove, a construction which has rendered repairing of the grate somewhat difficult, as it has been necessary to remove the brick from the fire pot in order to reach the grate frame The objections have now been overcome by forming a support or frame work for the main portions of the grate, which is independent of the frame of the stove, being supported by it, but not forming an integral part of it. The end of the stove is so constructed that the grate and frame may be moved latterally upon the frame support below the fire-brick entirely through the end of the stove, a section of the front wall of which is detachable.

THE PERRY STOVE COMPANY, Albany, N. Y., have started in on a most successful season. The shipments of oil goods, of which the company carry a large line, are said to have been five times as great as they were last year for the same period; in other words, where the company had sold 2000 lamp stoves up to this date last year, they have disposed of 10,000 this season. The inventive genius of Superintendent R. Z. Liddle is constantly at work conjuring up new features and improvements in the oil-stove line. His simplification of the burner, so that it easily comes apart and admits of being thoroughly cleaned, was brought out last season and is now bearing good fruit. The orders are very large. His device for making the wick always turn up evenly is a valuable feature and has evidently been appreciated by the trade, if large sales are any criterion. The company have for this season an entirely new line of oil stoves and ranges, embodying all their latest improvements. The Royal C has a two-hole top, with extension shelf, and can be fitted with all convenient furniture, such as oven, flat-iron heater, &c. It has 4 inch burners and the stove is entirely nickeled. It is of a handsome design throughout. The Royal D is a larger one of the new series and has a three-hole top. It also can be fitted with all the furniture. The Royal E has a four-hole top and is as handsome as the others. This line is already beginning to have a decidedly prosperous run. The doors of the three new stoves have three mica windows and are of a very handsome design. They are fitted with the patent burner. There is also a larger line of oil stoves and ranges known as the Royal 33, 44 and 55. These have three, four and five 5-inch burners respectively. They are of a most elegant and pleasing pattern. They are furnished with three and four hole tops, and also any furniture desired. The Royal range No. 44 has been placed on a neatly designed new stand, which has rollers. It makes a convenient and handsome outfit. Besides the new features mentioned, the company have the same attractive line heretofore offered to the trade.

STOVE MANUFACTURERS have been so dilatory in effecting their arrangements for World's Fair exhibits that we are unable this week to delight our readers with descriptions of the grand effects in black and nickel that will make the stove section of the exposition conspicuous. At present writing some of the booths have not been completed, and there will have to be a tremendous concentration of skill, muscle and energy to be able to present much of an appearance on Monday, the opening day. Some very prominent stove houses, which had intended to exhibit, surrendered their space within the past two weeks, but this has pleased other exhibitors, among whom such unappropriated space has been divided, thus giving them more than they had ever hoped for. Thus those who have held out to the end have been rewarded for their perseverance, and there will consequently be a number of very fine stove displays that will reflect credit on the trade. The space finally assigned runs from 800 square feet to 400 feet, quite a number having 700 feet, or 20 x 35. The pavilions erected are separate constructions, involving considerable outlay.

JAMES BOYLE & Co. of Salem, Ohio, have issued a very neat salesmen's card, ornamented with a panel picture and provided with a silken cord for hanging. The scene depicted is a landscape having in the foreground two setters which, from their actions, have evidently discovered their game. Beneath the picture is the inscription: "The dogs 'point' the fact that Keystone stoves are the best you can handle, and I will call on you soon prepared to 'back' their 'stand.' Please wait and see what I have to offer. Yours truly, T. C. Read." Diagonally across the upper left hand corner of the card carrying the picture are the name and address of the company, while at the left are the words: "Keystone stoves are the best."

THE DETROIT STOVE WORKS have just completed a fine woodcut, giving an excellent view of their foundries at Detroit, Mich. The buildings are shown to be of great extent, covering a very large inclosure, and stretching out an almost interminable distance. The warehouses, running six stories in hight, are in the foreground, with the molding shops running far out in the rear. Signs bearing the words "Jewel Stoves and Ranges" are conspicuous on the fence surrounding the works and on the tops of buildings. Over the engraving is the legend "Largest Stove Plant in the World," which we are not disposed to question after seeing the character of the buildings here portrayed, which look extensive enough to form almost a city by themselves. The new trademark of the company embellishes a corner of the cut, with its conspicuous statement "The Original Detroit Stoves," something to be very proud of at this day, since Detroit has won such distinction in the stove trade as a stove center.

THE MICHIGAN STOVE COMPANY are sending their friends and patrons throughout the country circulars giving full particulars how to get good accommodations at reasonable prices in Chicago during the World's Fair. The company had received so many letters in reference to securing quarters for their friends that they took the trouble to investigate the subject, and found that the best way to accomplish this purpose was by each person corresponding direct with the Bureau of Public Comfort, Rand-McNally Building, Chicago. A circular fully describing the plan followed by this bureau has been sent to no less than 13,000 people by the Michigan Stove Company. It is an official appendage of the World's Fair, organized for the special purpose of directing inquirers to suitable hotels and rooms as well as looking after their interests in other ways. These circulars are so full of the very information that intending visitors to Chicago are in search of that they are well described by the company as "worth their weight in gold."

THE MOLDERS' STRIKE in Chicago, which was ordered by the union on the 24th inst., covered only the machinery and jobbing foundries, and did not include the stove foundries. The strike is to enforce a demand for an advance of 25 cents per day on time workers' wages and 10 per cent. advance on piece work, with a minimum of $2.75 per day. It is understood that the stove molders have not abandoned their purpose of securing an advance in wages, but are waiting for the outcome of conferences between committees representing themselves and the manufacturers. Nothing definite may be accomplished until the annual convention of the National Association of Stove Manufacturers meets in Detroit on May 31.

THE FIRST SATURDAY IN MAY will start the summer half holidays for the stove houses on Second street, Philadelphia. Some will extend them to the middle of September.

AN AIR SUPPLYING DEVICE for use with stoves or furnaces forms the basis of a patent granted not long since to C. K. Killie of Mooreatown, N. J. The object of the invention is to so construct a device for supplying air to stoves and furnaces that the air will be projected into the gases as they rise from the fuel in a manner calculated to promote combustion.

Major M. P. Low.

The members of the stove trade, especially in the Eastern section of the country, will learn with deep regret of the death of the well-known veteran of the trade, Major M. P. Low, which occurred on Monday, April 17, of cerebral hemorrhage. He was stricken early in the day and became unconscious, remaining so until evening, when he passed quietly away. Major Low was regarded by his friends in the trade as a high authority on matters past and present relating to the stove trade, and his letters and reminiscences, published a short time since, were widely read and appreciated. He was a native of Dutchess County, where his parents were early settlers. During the war he was largely engaged in supplying the Government with stoves, but later met with reverses by reason of indulging his friends. The Major was held in high esteem for his pleasant ways, his genial manners and his charitable disposition. His face will be greatly missed from the haunts which for many years knew and felt his presence, and the trade at large will feel that it has lost one of its best members. Major Low was 78 years of age at the time of his death. The interment took place in Greenwood Cemetery on Wednesday, the 19th inst.

The high prices paid for cotton seed at the oil mills have caused a scarcity of seed for planting purposes. A few years ago the seed was burnt as refuse.

New Orleans papers encourage the erection of cotton mills in that city, arguing that it is the greatest market in the world for the raw material, enjoys unrivaled shipping facilities for the export trade and would be able to undersell Lancashire in all foreign markets.

TRADE REPORT.

The Iron Market.

The events of the past week in Eastern markets have not been such as to give much comfort to those who have been looking for favorable developments in the Iron and Steel trades. On the contrary, the feeling has become one of extreme depression, and it is a question now whether it will be possible to maintain even the present unsatisfactory position. It is not a question of business so much as a question of prices. The volume of business is large enough—almost, if not quite, the largest on record, yet manufacturers all say they are making no money, and as there is neither a prospect of lower cost nor of higher prices, the situation is indeed gloomy. Naturally the question arises, "Why don't manufacturers get better prices?" It is easy enough to ask the question, but not easy to answer it. In the first place, the capacity for production has expanded enormously, and in the next place, the demand, while large, is in some lines from 20 % to 30 % less than productive capacity. On an average, the capacity actually in operation may not be more than 5 % to 10 % in excess, but it is the 5 % or 10 % excess, or whatever the amount may be, that makes the price for the entire product. Some people think the only way out of the difficulty is to pattern after the Steel Rail arrangement, and something of the kind is said to be under consideration as regards Plates and Shapes; 10¢ or 15¢ ℔ 100 lb extra would be a wonderful advantage to manufacturers, without being any detriment to consumers. As matters stand to-day the outlook is very unsatisfactory, although, as we said before, there is business enough—what is wanted is better prices.

During the week under review there were some heavy transactions in Bessemer Pig and Steel in the Pittsburgh market, but at prices considerably lower than have been touched for several months. From the fact that these transactions were brought about largely by reason of concessions on the part of sellers it cannot be claimed that there has been any general improvement in the situation. News of the financial troubles of the Pennsylvania Steel Company was received on Friday, 21st inst., and created considerable surprise in business circles, as the concern were supposed to be in good condition. As far as known, no Pittsburgh firms are affected, but the failure has added considerably to the feeling of uneasiness which prevailed there before it occurred. Loans are negotiated with more difficulty, the banks drawing the credit lines tighter than for some time past. There has not been a business failure of any consequence in Pittsburgh for a long time, and this is considered remarkable, when the low prices at which materials of nearly all kinds have been selling are taken into account.

At Chicago the unseasonable weather is affecting all classes of business. A very few days of spring have been followed by a recurrence of genuine winter, and the season is now fully a month later than usual. The failures in the Eastern Iron trade cause an uneasy feeling here, but no worse effects have yet shown themselves. The strike epidemic is now in full vigor, and considerable disturbance to trade is due to this cause.

Pig Iron.—Current business in New York is generally reported quite light. So far as buyers are concerned there is absolutely no snap in the trade. During the last few weeks considerable quantities of Charcoal Iron have been distributed throughout this territory and Connecticut, some of the Iron going as far South as Richmond and Roanoke. It represents a part of a stock of 9000 tons held for a good many years by a Lake Superior furnace, for which at one time $34 was offered and declined. This Iron is now selling on the basis of $15.75 @ $16, Buffalo, for the chilling numbers. We quote Northern brands at $14.50 @ $15.25 for No. 1; $13 75 @ $14.50 for No. 2, tidewater. Southern Iron, same delivery, $14.25 @ $14.50 for No. 1; $13 @ $13.50 for No. 2 and $13.25 @ $14 for No. 1 Soft.

From Philadelphia we learn that, in spite of all unfavorable influences, Pig Iron is beginning to attract attention because of its statistical position. Good Irons are scarce, scarcer than they have been for months past, and those who are bound to have first-class brands are lucky if they can get what they want at quoted rates. There is Iron enough, of course, but after making all due allowances, there is less Iron to be had to-day at a given price than there has been at any time since last summer. Business is not in such a condition as to warrant holders in asking higher prices, but they won't shade quotations, and in some instances are not taking all the orders that are offered even at their own prices. They are under contract for about all the Iron they can make up to the middle of July or August, and under present conditions are not disposed to engage beyond that. From present appearances it is probable that business will be somewhat curtailed until it is seen what will turn up within the next 30 or 60 days. There is plenty of room for improvement, and very little chance of anything less favorable as regards this particular interest, but with so many contingencies to meet in the very near future both buyers and sellers are inclined to restrict operations within the narrowest limits possible. Meanwhile, the usual asking prices are about as follows for Philadelphia and equivalent deliveries, with 25¢ @ 50¢ less on Southern brands at Harrisburg and intermediately to Baltimore:

American Scotch, No. 1X.....	$16.00	@ $16.50
American Scotch, No. 2X.....	15.00	@ 15.50

The molders in the jobbing foundries at Chicago were called out by the union on Monday to enforce a demand for an increase of 25¢ per day to day workers and 10 % advance on piece work. Some employers have yielded to the demand, but the great majority are allowing their foundries to stand idle. This has caused considerable falling off in the Pig Iron demand, and there is much uncertainty for the future, as it is not known how long the strike may last. Local Irons have been quiet, but prices are unchanged. A great variation is perceived in quotations on Southern Coke, there being a spread of at least 75¢ ℔ ton between the figures asked by the leading companies and those quoted by small concerns, which are still anxious for business. Our quotations represent the medium prices asked by representatives of Southern companies, which are shaded from 10¢ to 25¢, according to circumstances. Quite a number of orders are in sight from outside buyers, but they are holding off at present in the expectation that existing conditions may lead to still lower prices. It will, perhaps, be well for the foundry trade if the strike should last for a little time, as competition for business among the foundrymen has been so keen that unusually low prices have been made for Castings. It is reported that $28 ℔ ton has been named on Castings not of the simplest form. Lake Superior Charcoal Iron is quiet in this immediate vicinity, but some good-sized sales are reported in outlying districts. A 1000-ton lot was sold at a price equivalent to $16.75, Chicago, and another lot of nearly the same size brought about $16.50. Small transactions are occurring at our quotations. Collections are slow, and generally speaking the condition of business is unsatisfactory to sellers. Quotations are as follows, cash, f.o.b. Chicago:

Lake Superior Charcoal.....	$16.50 @	$17.00
Local Coke Foundry, No. 1.....	13.75 @	14.25
Local Coke Foundry, No. 2.....	13.00 @	13.25
Local Coke Foundry, No. 3.....	12.75 @	13.00

In Southern markets there has been a fair demand for Pig Iron from consumers during the week, and the market may be called a steady one, although there

have been rumors of cutting in prices, which, if it has been done, as is not improbable, for there are frequently some furnaces making concessions to effect sales, is exceptional. The standard Iron companies in the Tennessee and Alabama districts are firmly adhering to the price of $9 for No. 2 Foundry and $8 for Gray Forge, f.o.b., Birmingham. Orders are freely taken on this basis for delivery up to September, and it would not be difficult for buyers to secure any delivery this year at these rates. Further sales of Mottled Coke Iron have been made at $7.90, f.o.b., Birmingham, at which price there appears to be a demand for all offered. Charcoal Iron is in rather better demand with favorable prospects of further buying by car works. There has been considerable Southern Iron taken for Eastern shipment, and although the buying is generally in small lots and seldom runs over 1000 tons in any one order, yet the aggregate is of considerable proportions. There is no longer any apparent anticipation of better prices during the summer and the trade seems to have settled down to a willingness to sell at current rates, but not to make concessions. Quotations are as follows:

Foundry.

Southern Coke, No. 1	$13.25 @ $13.50
Southern Coke, No. 2	11.75 @ 12.00
Southern Coke, No. 3	11.00 @ 11.25
Ohio Soft Stone Coal, No. 1	16.00 @ 16.25
Ohio Soft Stone Coal, No. 2	15.00 @ 15.25
Mahoning and Shenango Valley	14.75 @ 15.00
Hanging Rock Charcoal, No. 1	19.00 @ 19.25
Hanging Rock Charcoal, No. 2	18.00 @ 18.50
Tennessee and Alabama Charcoal, No. 1	15.50 @ 15.75
Tennessee and Alabama Charcoal, No. 2	14.50 @ 14.75

Metal Market.

Copper.—All reports are to the effect that business has been slow in the local market and that the general situation is quite as cloudy as it has been at any previous time since the beginning of the year. As far as the reduction in the output is concerned there seems to be no force except, possibly, in checking a more or less serious depression in values. In any event it is the fact that 11¼¢ has become a common selling price for Lake Superior Ingot, while occasional transactions at a shade less have been noted and offers made to sell at 11.15¢ for distant future delivery on the Metal Exchange. Casting brands are also somewhat irregular, with 10½¢ the top quotation, and more than a vague possibility that really desirable orders would be taken at ⅛¢ @ ¼¢ less by some smelter. At the close there were rumors to the effect that one of the prominent Lake Superior producers has recently closed contracts with American consumers at 11¢ ℔ lb.

Pig Tin.—Prices were held quite stiffly by the "bull" interest during the early part of the week under review, on the basis of about 20¾¢ for spot stock. Speculation, however, figured less conspicuously than clever work in the direction of quietly moving out as much Tin as possible into the hands of interior dealers and consumers. Importations of 365 tons in a few days caused an accumulation that proved rather burdensome, however, and in connection with lower prices from London, led to a decline in prices to 20.60¢ for prompt and current month delivery. At the lower prices over 200 tons changed hands, chiefly for prompt and April delivery.

Pig Lead.—Owing to freer offering, along with manipulation by operators who wish to lower prices and rumors of some sales of foreign Lead on the basis of 4.17½¢, landed here, the market has weakened perceptibly. A few carloads were placed at 4.15¢; subsequently more went at 4.10c, and later on some lots at as low as 4.05¢. The latter price is below the importing point and buyers therefore manifest rather more interest again, although Western markets show some response to the late depression here.

Spelter.—Business in this metal has been very slow and the position of the market is practically the same as it was at the date of our last review. Western brands may be secured to a limited extent at 4 40¢, delivered, but most holders want 4.45¢ upward, and the offering at present is very moderate.

Antimony.—Outside of routine jobbing trade there has been little doing and prices remain almost stationary at 10¢ @ 10½¢ for Hallett's, 10¾¢ @ 10½¢ for L.X. and 10¾¢ @ 10¾¢ for Cookson's.

Tin Plate.—The market has remained stationary, that is to say, business in both spot goods and forward shipments has been on strictly conservative lines, while the movements in prices were confined almost wholly to special figures secured by energetic brokers on what are commonly termed "snap" lots.

Coal.

At the meeting of sales agents on Tuesday the Western trade made a reduction from $1.90 to $1.75, equal to 15¢ ℔ ton, to conform to the previous reduction in the Eastern market made last March. Eastern prices remain unchanged. The company prices are firm at the adopted schedule, but trade is very slow, as usual at this season. Free Burning is quoted $4.15 alongside, and Hard Lehigh is 15¢ @ 25¢ ℔ ton more. Pea Coal is $2 50 @ $2.75, and Buckwheat is so scarce as to be scarcely quotable, but is about $2 @ $2.25. Cumberland Coal is $3.10 @ $3.15, f.o.b. Lower tolls on the Pennsylvania Railroad places Clearfield at a disadvantage where tolls remain the same. The Eastern demand is good.

The week's production of Anthracite is 800,000 tons; for the year, 11,614,903 tons—increase this year, 1,029,068 tons. Reading tonnage, 405,000 tons. Pennsylvania tonnage, 307,266 tons Coal and 104,482 tons Coke. An accumulation of interior and tide-water stocks is in progress. Mill and factory requirements are quite large, and small steam sizes are moving quickly.

The Flat Top operators in Virginia agreed upon an output this year of 5,000,000.

The new shaft of the Lehigh & Wilkesbarre Coal Company at Ashley, Pa., will have 90 feet of coal.

Financial.

A notable event occurred during the week when the traditional "dead line" was crossed in disbursing gold from the United States Treasury, and the $100,000,000 reserve was invaded, as a consequence of another shipment to Europe amounting to more than $6,000,000. As high as $4.89½ per pound sterling was paid for demand bills, entitling the holders to payment in gold in London, and rates for call loans suddenly advanced to 10 @ 12 %. On the part of some there was a disposition to construe the conditions prevailing in the sterling exchange market as a premium on gold. Simultaneously Secretary Carlisle issued a statement of his policy with reference to the payment of notes given in payment for silver bullion, to the effect that those payments would be made without discrimination so long as there was gold available for that purpose. He said: "The purpose of the Government to preserve its own credit unimpaired and maintain the parity of the two metals by all lawful means will not be abandoned under any circumstances," and, as if to silence conjecture, President Cleveland authorized a statement substantially reiterating the language of the Secretary. The feeling of anxiety in monetary circles was in a measure allayed, bankers and others conversant with the situation becoming assured that the Government could deal successfully with the grave financial problems awaiting a solution. Moreover, the inroad upon the gold reserve was soon made good by tenders from Western banks. An unexpected feature was the active buying of stocks on foreign account, after which the rates for sterling and call loans both declined.

On Friday, following the Treasury statement, quotations were generally ½ @ 2 % higher than on the previous day, which was considered a favorable omen considering the fact that the $100,000,000 reserve had been encroached upon for the first time since the resumption of specie payments. The threatened cataclysm having been averted, the presumption was that further withdrawals of specie for export would excite little apprehension. In any contingency the parity of gold and silver would be preserved. But it was not until Tuesday morning that the financial sky began to clear. Then the fact was given publicity that on the previous day the newly appointed Sub-Treasurer Conrad Jordon, just from Washington, had submitted at a conference of leading bankers and financiers a definite proposition from President Cleveland for a gold loan to the Government of $50,000,000, secured by a 3 % bond redeemable at the option of the United States Treasury. With some proposed modifications the scheme was cordially indorsed and now awaits the approval of the chief executive. Half of the amount named, it is conjectured, will at once be put upon European markets. Thus reinforced the Treasury will be equal to any emergency until Congress shall apply a permanent remedy.

The stock market on Monday, influenced

by the statement by President Cleveland to the effect that there would be no change in the policy of the Treasury Department with respect to the Treasury notes of 1890, and that the parity between gold and silver would be maintained as contemplated by the act of July, 1890, opened strong and there was good buying for arbitrage account and to cover short contracts. The strongest were the industrials, the grangers, Missouri Pacific, Louisville & Nashville, Reading, Lackawanna, the Vanderbilts and Chicago Gas. Later news of the engagement of over $3,000,000 gold for export to Europe and Canada brought about an irregular decline. Toward noon it was reported that the Boston banks had offered $4,250,000 gold to the Government.

The Government bond market during the week was heavy for the Ext. 2s and 4s, but steady at unchanged prices for the currencies. Closings compare as follows:

	April 24.	April 15.
Ext. 2s, reg	99 @ ..	99⅝ @ ..
4s, 1907, reg	112⅝ @ ..	113 @ 113⅜
4s, 1907, coup	112⅝ @ ..	113 @ 113½
Currency 6s, 1895	105 @ ..	105 @ ..
Currency 6s, 1896	107½ @ ..	107½ @ ..

The merchandise markets are yet awaiting the spring revival. Wheat and flour are again lower, affected by large visible supplies and currency questions, and there is a fair export movement at the decline, which is expected to gain momentum on the arrival of the grain fleet, already started through the lakes. Provisions are dull and all pork products are dear on account of the scarcity of hogs. Cotton is weak and spot $\frac{5}{16}$¢ lower. Spot coffee declined about ½¢.

Chicago Report.

Scrap.—Wrought Scrap constinues quiet, but Borings, Turnings, Stove Plate and other cheap stock are in good demand. Dealers' buying prices are as follows:

	Per net ton.	Per lb
No. 1 Wrought Scrap	$13.00	....
Machinery Cast	10.00	....
Malenble Cast	7.00	....
Stove Plate (free of burnt)	8.00	....
Burut Iron and Grate Bars	5.00	....
Sheet Iron and Hoops	4.00	....
Plow Steel and Breaking Stock	8.50	....
No. 2, such as Shovels, Hoes, &c.	4.50	....
Old Boilers—whole (Iron)	8.00	....
" (Iron)—cut in single Sheets and Rings	12 00	....
Old Gas-Pipe and Boiler Tubes	9.00	....
Cast Borings	5.00	....
Turnings	6.00	....
Horseshoes	12 50	....
Copper Bottoms	....	8¢
Copper Clips and Heavy	....	9⅛¢
Heavy Brass	....	8⅛¢
Light Brass	....	4 ¢
Pipe Lead	....	3 ¢
Tea Lead	....	2¾¢
Zinc	....	3 ¢
Rubber	....	9 ¢

Anthracite.—In accordance with previous announcements, a new price liat became effective on the 25th inst., making a reduction of 50¢ ₹ ton. Carload lots of 12 net tons are now quoted as followa:

	Egg, Grate.	Sto. and Cb.
Chicago, Ill	$5.35	$5.60
Milwaukee, Wis	5.35	5 60
Kansas City, Mo	8 55	8.80
Council Bluffs, Iowa	8.55	8.80
St. Joseph, Mo	8.55	8.80
Leavenworth, Kan	8.55	8.80
Omaha, Neb	8.55	8 80
Burlington, Iowa	6.85	7.10
Des Moines, Iowa	8.30	8.55
Davenport, Iowa	6.65	6.90

Denver	$8.00
Pueblo	8.00
Colorado Springs	8.00
Leadville	8.00
Cheyenne, Wyo	10.00
All points between Denver and Missouri River	9.35

CONDITION OF THE

Hardware Trade.

WHILE the unfavorable weather has interfered seriously with business in some sections, on the whole it may be reported as very satisfactory in amount. There is, however, a slowness in collections, which is particularly noticeable in the South and Southwest.

Advices from Chicago.—Shelf Hardware is in reasonably good demand, but trade does not seem to be increasing, the weather cutting a very important figure in fluctuations in the volume of business. Last week snow fell throughout a large part of the Northwest, reaching a depth of 20 inches in some localities. This has not only checked seeding, but has also prevented most kinds of outdoor work. The season is believed to be fully a month late. Staple goods of all kinds are affected by the backwardness of the season, and weakness is visible in some unexpected quarters owing to the necessity of moving accumulated stocks. Wire Cloth is an exception to this condition, the price still climbing. Some of the trade are inclined to think that it will reach $2 before the upward movement is checked. A large order for Poultry Netting for the World's Fair buildings was placed with the Gilbert & Bennett Mfg. Company, the Clinton Wire Cloth Company and the New Jersey Wire Cloth Company, with one or two smaller concerns, amounting in all to about 1700 rolls of 48-inch netting. Considerable stir has been caused by this order, though the statement is made that it is not a full day's work for the factories, but it came at a bad season of the year, with light stocks in manufacturers' hands, and, therefore, had to be distributed among a number of concerns. The placing of this order has had no effect on prices. Heavy Hardware is moving very well. Jobbers report no particularly encouraging features except that a steady flow of small orders from day to day keeps the volume of business in fair condition.

Notes on Prices.

Cut Nails.—The mills are naming lower prices, although the demand is active and the volume of business large. We quote $1.15 for carload lots at mill, and in larger quantities this price is in some cases shaded. New York quotations are still $1.40 for small lots from store.

Advices from Chicago.—Factory lots of Cut Steel Nails are now selling at $1.30 to $1.35 here, according to the character of the order. Specifications are coming in freely to manufacturers on old orders, but the competition of outside mills keeps prices down, while new business is rather slow on account of the broken weather. Prices from store are $1.40 to $1.45, according to quantity.

Wire Nails.—The manufacturers held a meeting last week and after a full consideration of the condition of the market adjourned without making any change in price. The makers have all booked large orders which will absorb their production for several weeks and are therefore not anxious for orders. Jobbers being generally well supplied there are not many large orders on the market, although the goods are going off rapidly into general trade. We quote without change $1.55, f.o.b. mill, with Cleveland as the point of equalization for the West and Pittsburgh for the East. Small lots from store in New York are held at $1.80 @ $1.85.

Advices from Chicago.—The price of Wire Nails was not advanced by the manufacturers last week, although a strong sentiment existed among them in favor of an additional 5 cents. Some of the jobbers are still underselling manufacturers, and it was not thought expedient to make another advance until this condition of affairs should change. The opening of navigation and the establishing of lower freight rates by lake has made the factory price $1.62½ here. Manufacturers report carload orders coming in very well, but no heavy orders. Jobbers quote small lots from stock at $1.70 to $1.75, and carloads $1.65.

Barb Wire.—There is no change in the condition of this market except that, as is natural at this season, the demand is falling off somewhat. We quote $2 45 to $2.50 for Four Point Galvanized in carload lots at mill. Small lots delivered in New York are quoted at $2.70 for Galvanized and $2 30 for Plain.

Advices from Chicago.—Trade in Barb Wire is very disappointing, on account of the backwardness of the season. New business is coming in very slowly, and there would be little done if it were not for the quantity of advance orders entered during the winter, on which shipments are now being made. Prices are maintained, buyers not asking for lower rates, but paying the price asked on such new orders for small quantities as they are sending in. We continue quotations at $2.20 and $2.60 for carload lots of Painted and Galvanized respectively. Small lots from stock are quoted at $2.30 and $2.70.

Wire Cloth.—This article was already becoming scarce and prices were materially stiffening when, on the morning of the 19th inst., the works of the Clinton Wire Cloth Company, Clinton, Mass., were very seriously damaged by fire, which will still further lessen the supply for some time. Prices are in consequence very strong and holders of stocks are in many cases naming prices which under other circumstances would be unreasonably high. We hear of both jobbers and manufacturers who are now holding firm at 2 cents a foot for goods from stock. Regarding the fire at

their works, the Clinton Wire Cloth Company have issued the following circular under date of the 19th inst.:

GENTLEMEN.—A portion of our works were partially destroyed by fire this morning.

We desire to notify you that the Hex. Netting department, with stock on hand, is intact and there will be no delay in deliveries.

The looms for weaving Screen Cloth are uninjured, but the painting plant is totally destroyed, and we shall be unable to deliver painted Cloth until the building can be replaced.

The mill for weaving coarse Cloth is partially destroyed, but as most of the looms are practically uninjured, stoppage in this department will be for a short time only.

Very respectfully,
CLINTON WIRE CLOTH COMPANY.

Perfect Tack and Brad Hammers.—L. A. Sayre, Newark, N. J., is manufacturing these Hammers. The Perfect Tack Hammer is sold to the trade at $3 per dozen, and the Perfect Brad Hammer at $2.75 per dozen.

Evans Garden Cultivator.—The cultivator is manufactured by the Evans Garden Cultivator Company, Paris, Mo., and is sold to the trade at $10.50 per dozen.

Eureka Tea and Spice Scale.—John Chatillon & Sons, 85 to 89 Cliff street, New York, who are manufacturing this article, are selling it to the trade from the following list, which is subject to a discount of 40 per cent.:

	Each.
With Brass Scoops and Brass Bails, all Nickel Plated	$9.00
With Brass Scoops and Brass Bails	8.50
" Tinned " " Iron "	8.00

The Prescott-Stanyan Bread Mixer and Kneader.—This article is put on the market by Edwin Prescott, 8 Medford street, Boston. The device is made in two sizes No. 1 with 7-quart pan and No. 2 with 8-quart pan. The trade price on either size is $3, subject to a discount of 25 per cent.

Gem Cake and Batter Mixer.—This article is manufactured by North Bros. Mfg. Company, Philadelphia. It is sold to the trade at $1.75 per dozen, subject to a discount of 20 per cent.

Gem Cake Pans.—North Bros. Mfg. Company, Philadelphia, who are making this article, are selling it complete, including one loaf and three layer pans, measuring cup and recipes, at $1.25, subject to a discount of 20 per cent. to the trade.

Tin Plate Cleaning Bran.—J. Irving Rogers, 53 Newcombe street, Liverpool, England, issues a price-list of "Cook Jenkins" Tinhouse Bran. The following prices are per ton net, f.o.b., Liverpool:

Special Pure Rice Shude Meal	50/
X.W. Shudes No. 1, fine	45/
X.W. Shudes No. 2, rough	42/6
No. 1 Tinhouse Bran	40/
No. 3 Patent Tinhouse Bran	40/
No. 4 Tinhouse Bran	36/6
V.C. Tinhouse Bran	26/6
No. 1 Shudes	42/6
No. 2 Shudes	40/
Pink Cleaning Machine Meal	24/
Special Dust	20/

Glass.—The Glass market for the past week shows few changes, the demand being moderate, and prices firm. The recent storms by which quantities of Glass was broken in some sections have caused a perceptible increase in the requirements to repair the damage done; while the same storms have necessitated a discontinuance of building operations, and curtailed the demand for Glass to be used in new buildings. There are indications that prices are stiffening, and that desirable sizes of Glass are becoming somewhat scarce. It is reported that in the new list issued by the Chambers Glass Company, the bracket prices for Glass of first and second quality are quoted from $1 to $1.50 per box higher than formerly, with discounts as adopted by the National Window Glass Company. Meetings of the National Window Glass Company are announced to take place this week in Philadelphia and New York. It is rumored that a new Glass list is in contemplation, but no official announcement has yet been made. Quotations are as follows: American Window Glass, 2000 boxes at one time, 80 and 10 and 10 per cent. discount; carloads, 400 boxes, 80 and 15 per cent. discount; less quantities than carloads, 80 and 10 per cent. discount. Freight allowed on car lots and over, not to exceed 17½ cents per 100 pounds; less than car lots, f.o.b. at shipping point. French Window Glass, 75 and 10 and 5 per cent. discount. American Plate ranges in price from 50 and 10 and 7½ per cent. discount to 60 and 5 per cent. discount. Imported Plate Glass, 60 per cent. discount to 60 and 10 and 5 per cent. discount.

Old Rubber.—The following are the current prices paid for Old Rubber delivered in New York:

Car Springs, in ton lots, ℔	....	@	$0.03½
Rubber Shoes, in ton lots ℔	....	@	.04
Large Hose, ℔ ton	....	@	9.00
Wringer Rolls, ℔	....	@	.04½

Mixed Rope	℔	¾ @	⅞¢

Curtis & Curtis, Bridgeport, Conn., manufacturers of Pipe Threading and Cutting Machines, will add to their plant a new building 33 x 55 feet, two stories high, to be completed in July

Trade Notes.

E. T. BARNUM of Detroit, Mich., has issued an invitation to his friends in the trade who contemplate visiting the World's Fair, to call and examine his exhibit of a Wire house. This is made entirely of Wire and filled with Ornamental Wire and Iron goods. The exhibit is located in Section H, Block 3, No. 11, in the extreme northwest corner of the Manufacturers' Building, near the United States Government Building.

WILLIAM T. HAIN, Reading, Pa., issues a neat illustrated circular and price-list of William T. Hain's New Keystone Roasting and Bake Pan, for poultry, meats, fish, bread, cakes, puddings, &c. A cut shows the appearance of the Pan and its special features are fully described.

WE HAVE BEEN FAVORED with a circular from Armbruester Brothers' Art Smithery and Iron Works, Frankfort-on-the Main, Germany, which gives a view of the handsome Wrought-Iron Gates made by the firm for the main entrance to the German division of the Manufactures and Liberal Arts Building at the Columbian Exposition. The Gates are very elaborately wrought after designs of their own. Armbruester Bros. announce that they will be represented at the World's Fair by a large collection of artistic Wrought Iron goods, including some fine Locksmiths' work in various styles.

THE ANNOUNCEMENT this week of Haydock & Bissell, 12 Murray street, New York, relates to a sale that will interest many of our readers. On May 2 and 3 they will sell at auction several thousand cases of Agate and Granite Ware and Blue and White Ware by order of the Lalance & Grosjean Mfg. Company and the St. Louis Stamping Company. In the announcement elsewhere in this issue all the necessary particulars are given respecting this sale.

THE COMMON SENSE TEA KETTLE, manufactured by the Common Sense Tea Kettle Mfg. Company, Mount Morris, N. Y., is illustrated in their announcement elsewhere in this issue, and the advantages of the construction are alluded to in the text of the advertisement.

WE ARE INDEBTED to Hammacher, Schlemmer & Co., 209 Bowery, New York, for a copy of a very attractively arranged catalogue of Drawer Pulls and other Brass Trimmings furnished by them. The publication bears date of April, 1893, and presents within its covers a large assortment of the class of goods mentioned. The printing is in two colors, and the illustrations are supplemented with a price-list and index. Accompanying this volume is another pamphlet showing illustrations of an odd stock of Drawer Pulls and fancy Brass Trimmings which the firm are closing out at low prices. The goods embrace Drawer Pulls, Escutcheons, Knobs, Hinge Plates, Umbrella Arms, Hat Pins, &c., &c.

A. L. BURTIS, Lockport, N. Y., with whose name many of our readers are familiar, is an expert in all manner of sheet metal work. But his abilities are by no means confined to the manipulation of tin plate and galvanized iron. Like the tinners, or as they were then known the "tinkers," of the Middle Ages, he has much musical talent and has had many years' experience in the leading of orchestras.

M. STRANSKY, importer of German Enameled Steel Ware for culinary and kitchen use, is now in Europe looking after matters pertaining to his business. He is now expected back the middle of May, having sailed from New York April 4 on the "Aller."

THE GLOBE VENTILATOR COMPANY of Troy, N. Y., issue a couple of advertising cards that are got up in a very clever manner and in the line of humorous advertising are far in advance of the usual work of this kind. The cards are printed in white line engravings and letters on a black ground. One shows a section of a Globe ventilator with little winged skeletons escaping from the top and the accompanying text in rhyme is a lament of a consumption germ, who complains that business is dull now that the Globe ventilators are used. The second card carries the following verse with an appropriate illustration:

"Hot nights at the torrid Equator,
Kept sleep from a huge alligator;
Nor could he repose
'Till he rigged on his nose
An effective small Globe ventilator."

ASHLAND EMERY MILLS, Perth Amboy, N. J., after investigating the merits of Naxos Emery, have adopted it as a substitute for Corundum. This, they state, does not supplant their Turkish Emery, but with them will replace Corundum for all purposes for which Corundum is used. To avoid confusing it with their Turkish Emery, they have denominated it Naxos Corundum, which name, they remark, more fairly represents the article, as it carries a large percentage of Sapphire Corundum.

WASHBURN & MOEN MFG. COMPANY issue a neatly bound pamphlet containing handsome illustrations of the buildings at the World's Columbian Exposition, with a description of each. The illustrations include the Administration Building, Government Building, Art Palace, Machinery Hall, Agricultural Building, Manufactures and Liberal Arts Building, the Woman's, Transportation, Fisheries, Electrical and Horticultural Buildings, and the Hall of Mines and Mining. Useful information is given for visitors, also a list of the principal hotels, restaurants, railway depots, theaters, museums and fine buildings.

C. M. AVERY, Somerton, Philadelphia, Pa., has been appointed direct representative of N. R. Streeter & Co., Groton, N. Y. The sale of this firm's Sensible Cold-Handle Sad Irons is reported to have considerably increased during the past few months, an improvement being also noted in sales of their other goods. Mr. Avery has also been appointed direct representative of the Crandall Machine Company, Groton, N. Y., for the sale of their line of Standard Adjustable Chain Pipe Wrenches.

Prize Competitions

$25.00.

Prize Competition No. 22.

SUBJECT:

The Best Manner of Presenting and Collecting Book Accounts.

While circumstances must in many cases regulate the manner and time of presenting and collecting accounts in a retail business, it is necessary to have rules to be followed in the majority of cases. This competition is designed to draw out descriptions of methods which yield the most favorable results. Such points as the following may be touched upon:

Should accounts be collected at stated intervals?

How should they be presented to insure prompt payment?

If in person, who is the proper one to present them?

How can this best be done without giving offense?

With old accounts do collection agencies produce good results?

Is it desirable to have local organizations and black lists?

What percentage of accounts can a concern afford to lose per year?

This competition will remain open until May 20, 1893.

Those intending to compete are reminded that it will not be necessary to write long essays, but that comparatively brief and business-like answers will be favorably regarded as meeting the purpose for which these competitions are announced.

The following prizes will be awarded:

First prize	$12.50
Second prize	7.50
Third prize	5.00

The prizes will be awarded for answers which in the judgment of the committee of award are most suitable for publication and of the most general interest. We reserve the privilege of extending the time on any competition in case the contributions received are not of sufficient number or merit for the committee to award prizes. These competitions are open to every one, and it is hoped that there will be a general response from business men. We shall have the privilege of publishing any or all of the contributions received.

Replies are to be received not later than May 20, 1893. They should be addressed as follows:

DAVID WILLIAMS,
96–102 Reade street,
New York.
Prize Competition No. 22.

The committee to whom the contributions in Prize Competition No. 8 were referred have awarded the prizes as follows:

First Prize of $50 to FRED. MACEY, Grand Rapids, Mich.

Second Prize of $25 to HENRY C. WISEMAN, Springfield, Ohio.

Third Prize of $15 to S. T. MOORE, Milroy, Pa.

Fourth Prize of $10 to F. W. HUFF, Philadelphia, Pa.

Other Competitions which have closed are now in the hands of the Committees of Award, who are giving careful attention to the claims of the different contributions. From the number of these and the evident merit of not a few of them, we are assured that a great deal of valuable information and suggestion will be put at the disposal of the trade.

The Weekly Prize Competitions noted below are now before our readers and remain open until the dates named:

No. 19. Closing April 29.
Electrical Goods as a part of a Hardware Stock.

No. 20. Closing May 6.
A Reliable System for Securing the Correct Charging of All Goods Sold on Credit.

No. 21. Closing May 13.
The Safety Line in Credit Business.

No. 22. Closing May 20.
The Best Manner of Presenting and Collecting Book Accounts.

Another subject will be announced in our next issue.

Opening of the World's Fair.

In accordance with the set programme the gates of the World's Columbian Exposition were thrown open to the public on Monday. Appropriate exercises graced the event. The President of the United States pressed the button which started the ponderous machinery, and numerous distinguished representatives of American official life, as well as of foreign powers, added impressiveness to the occasion by their presence. The managers of the exposition were complimented for the ability and energy they had displayed in making the stupendous preparations necessary for the reception of a very large part of the best the world can show in mechanical and artistic achievements. The people of Chicago were especially proud of the fact that their city was the favored location for the four hundredth anniversary of the discovery of America, and welcomed to their midst the Duke of Veragua, the lineal descendant of the great discoverer. In the heart of the continent, almost 1000 miles from the seaboard, he beheld one of the greatest triumphs of civilization, the creation of gorgeous palaces, in which, in honor of his distinguished ancestor, the finest universal exposition was to be held.

Condition of the Exhibits.

Theoretically, the exposition is now in full blast and ready for the inspection of the people of the world. Practically, as shown in considerable detail elsewhere, the fair is not in proper condition to be visited and will not be for several weeks. Those who live within easy reach of it and can afford to visit it frequently will even now find a very great deal to interest them, and local patronage may run up to goodly proportions while the exposition is in its comparatively raw state. Residents of more distant localities, who can conveniently wait for a time and who do not expect to pay more than one visit to Chicago to see the exposition, will act wisely in deferring such a trip until late in May or perhaps in June. The exposition will be open for six months, and it should be seen at its very best in order to carry away the best impressions of its beauty as well as its magnitude.

Not a Money-Making Scheme.

We are not in sympathy with those who decry the exposition as a mere money-making scheme, with the celebration of the discovery of America as a pretext. This criticism could be made of every enterprise ever started and of every institution ever founded, save, perhaps, asylums, hospitals and churches. If it were not for the possibility of lucrative returns in some fashion human enterprise would be slow to engage in any undertaking, however pleasing it might be in contemplation. Expenditures in new schemes are not made if there is no hope of financial profit. As well might a man refuse to avail himself of the conveniences of a railroad, on the ground that somebody built it to make a profit out of transporting him, as to scent a possible money-making scheme in connection with an exposition and decline to visit it on that account. The mingling of sentiment and business is not unnatural, but one is the ally of the other, just as Machinery Hall and the Fine Arts Palace both belong to and are indispensable parts of the Chicago Exposition.

The Fair an Educator.

As the Centennial Exposition in 1876 was of incalculable benefit to our people in stimulating their inventive and artistic faculties, causing wonderful progress to be made in the development of a higher order of productive activity, so may the Columbian Exposition of 1893 prove to be another powerful educator, imparting its stimulus just when new life is needed. The direction in which this will be shown cannot yet be indicated, but there will be thousands of visitors from every section of the country who have the quick eye, the retentive memory and the constructive faculty that will enable them to use to good advantage hereafter the lessons learned in a course of visits to the World's Fair this summer. Let us all join in wishing the exposition complete success. Chicago's glory is the triumph of America.

Sheet-Metal Workers.

If it is true, as many of our correspondents say, that the educated workman is becoming more scarce, is it not the employer's fault to a considerable extent? In the sheet-metal trade the conditions are very much changed from even a quarter of a century ago. Instead of the old-time apprentice taken to learn a trade because he was not quite competent to become a professional man, but could turn a crank and grind out tinware, the present need is for a class of young men educated fairly and able to use drawing instruments and above all possessing the mental ability and mechanical taste to enable them to work from drawings and do a different piece of job work every day in the month. Such a person can get familiar with the use of the tools and machines in a very short time and make himself profitable from the start. The conditions needed to bring this class of men into the trade lies very much with the employer. A pleasant workshop, light and clean, a foreman who will instruct, but who at the same time will give the boy to understand that he must use his own brains for all they are worth, and pay that is graduated with advancement, will attract the better class of young men into the trade.

Electricity in Metal Working.

No one can predict to what extent modern methods of metal working are destined to be modified by applications of electricity. Electric welding is now quite extensively practiced. Electric casting has been shown to be practically possible in the Taussig process, wherein iron melted by electric heat is run into a mold connected with the apparatus in which the metal is melted, the time required for the execution of the work after the molding is completed being, for small castings, extremely short. Upon this follows the announcement that electric hardening and tempering of steel has been successfully carried out by some French electricians, who find that they can localize the hardening and tempering and confine it to an extremely limited area, or that they can so operate as to produce a hard skin over any desired extent of surface. An example is named of a steel bar hardened over its entire surface, but remaining soft in the interior. The facility with which heat can be produced by the electric current and applied to limited areas leads to the belief that it may find a useful application in the process of soldering, rendering easy the soldering of joints that are extremely difficult to make with the ordinary tools, and being particularly useful in soldering iron joints where the parts to be joined are so heavy that a blow-pipe flame or other analogous means are required for heating the parts before the solder can be applied. The possibility of producing a cheap apparatus for this purpose, adapted to use in shops, does not seem yet to have received the attention it deserves from electricians.

Interest in Heating Goods.

One of the effects of the severity of the past winter is now being made manifest in the heating trades in the large number of inquiries received, and this, too, in spite of the fact that the spring work of the builders is reported to be delayed by the weather from four to six weeks. These inquiries are largely due to the previous mild winters, which have permitted many heating plants to render service which has not been unsatisfactory until the stress of a good old-fashioned winter discovered their inefficiency. It is gratifying to feel that 1893 will probably be a good year for stoves, furnaces, steam and hot-water boilers, and that there will be enough work to go around, so that the disposition to make low prices may be checked. Many buyers who have experienced the result of low prices will

not look so kindly on cheap work in the future, but will inquire more closely into the quality and character of what they are getting. The delay caused by the weather will afford an excellent opportunity for a more careful consideration of all the rules that may be applied to each case, with the probability of better work resulting and better service being rendered. More important still is the likelihood of a closer accounting of cost of erection, so that those who have quoted too low in the past may see their error and join in sustaining prices at a figure which is remunerative though only fair from an intelligent standpoint. That there will still remain among the bidders on all work one who is away below the average is probable, but the effect will be less annoying and demoralizing if the many inquirers of the present materialize as buyers during the season.

Growing Use of Domestic Terne Plates.

It is idle for opponents of the American tin-plate industry to continue blind to the fact that American tin and terne plates of an unsurpassed quality are now being turned out in quantities from domestic factories, and are being more extensively used every week. Dealers in almost every section of the country concur in reporting a marked growth in the demand for plates of native manufacture, particularly ternes, which are preferred by users, not because they are home-made, but on account of their intrinsic value. It was rather startling to be told, as we were told the other day by a New York tin-plate merchant of standing, that it has lately become the exception for the customers of his firm to call for imported roofing plates. The concern in question have until a comparatively recent date handled nothing but imported tin plates. They did not keep the domestic article until forced to do so by the requirements of their customer Now a large stock of American terne is carried, and, to use the expression of our informant, "they go like hot cakes." Another merchant recently gave it as his opinion that the bulk of the roofing tin now being used in the United States is home-made. In the Western States the demand for American plates is so great that they use up all the products of the Western makers and send their surplus orders into the Eastern market. Manufacturers throughout the country generally report a ready sale for all the plates they can make, and many are unable to keep abreast of orders. No stocks of domestic plates are being piled up. Tin-plate works are nearly all running to full capacity, and are turning out a large and growing product. In the face of these facts we can only conclude that the American tin-plate industry has the practical support of those most deeply interested in the matter—namely, the consumers.

The fire losses of the United States for March are reported to be in excess of $16,000,000. "If this record is kept up through the year," says *Fire and Water*, "1893 will be the worst year the insurance companies have ever known. Already the losses have exceeded those of the corresponding period of last year, and the cry is, 'still they come.'" Our contemporary thinks that with heavy losses and restrictive legislation in the various States it will be surprising if there is not a withdrawal of considerable insurance capital by the retirement of companies before the close of the year. The business has been unprofitable for several years, and the outlook for the future is not encouraging.

Carbonic Acid at the World's Fair.

A scientific friend, who once took a course in pharmacy and therefore knows a thing or two about chemistry and physics, is greatly alarmed over the prospect of serious atmospheric disturbances in Chicago this summer, as well as seismic phenomena in remote regions on the earth's surface, as a direct consequence of the World's Fair. He reasons that the concentration of a half million or more human beings within the exposition grounds will cause such an enormous consumption of oxygen in that limited space that the great reservoirs of nature in the boundless ether will be called upon to supply the deficiency and air currents of frightful velocity will be created, causing cyclones, tornadoes, whirlwinds and hurricanes. The atmospheric equilibrium thus disturbed will enable the pent-up gases in other parts of the earth to accomplish a vent, giving rise to earthquakes and perhaps to eruptions of volcanoes. The huge quantities of carbonic acid exhaled from the lungs of the people, driven by the in-rushing winds, will, however, promote vegetation in other sections, as it is so beneficial to plant life; but that will, of course, be a poor compensation for the valuable lives which may be lost by the atmospheric disturbances. Being the inventor of a machine for the rapid generation of oxygen, he suggested modestly that the only sure way to avoid such a terrible catastrophe as he points out is for the fair authorities or the Government to purchase a sufficient number of these machines to supply any deficiency in the atmosphere, and place them on the grounds. We may add that our friend, who is something of an alarmist, lives neither in New York nor St. Louis.

Anti-Pin Hole Tin Plate.

Our readers will recall the discussions respecting pin holes in plates that have occurred in *The Metal Worker* in the past, and will be interested to know that Gummey, Spering & Co., Philadelphia, Pa., have put a plate on the market under the name "Gummey's Anti-Pin Hole Bright Tin Plate" which they say obviates the pin hole difficulty. The following extracts from a letter relating to this subject will be read with interest:

For a long time we endeavored to get a plate that was made of hammered charcoal bars, the same as tin plates were made 30 to 50 years ago, and we were successful in finding a works which has an old charcoal forge which was simply kept as a kind of curiosity to show the way plates were made from hammered charcoal bars. As you are aware, plates made of these bars are worth considerably more money on account of the extra cost in making the bars, but we have these plates in stock and have sold largely of them and in every instance they have given satisfaction, and persons who have had merely a sample box are now ordering largely.

Light Welsh Tin Plates.

An American buyer of Welsh tin plates, who says that he believes his firm to be "the only house in the United States which have not sold American tin plates, and do not wish to do so," has been constrained to write to his business correspondents in Liverpool protesting against the irregular weights of the boxes of plates now being sent to this country. Accompanying his letter he transmitted a list of the weights of boxes supplied to him by various Welsh makers, taken at random, which showed a remarkable variation in the weights. He also said that his firm had had repeated complaints from their customers of the uneven thicknesses of imported plates supplied to them. In the interests of Welsh makers he therefore warned them against the practice, which he predicted would ruin their American trade if such a course was persevered in. Part of his letter—which was published in full in a number of English papers—contained some strong sentiments, of which the following extract is an example: "If they (the Welshmen) would be only one-tenth part decent and one-ninth part honest they would have a nice business; but they are like the old criminal, when he could not do anything else he picked his own pockets, and they are certainly picking their own pockets to perfection at present."

This naturally has roused the wrath of certain Welsh tin-plate men, in particular that of a correspondent signing himself "Tin & Co.," who wrote a long letter to an English trade journal traversing the statements of the American merchant and defending the Welsh makers from the imputation of unfair dealing. The correspondent suggested that the weighings of a parcel of American-made tin or terne plates should be obtained and the results published, the inference being that the Welsh material would be found to come out well in comparison. This being beside the mark, has called out a further letter from the American dealer—who offers that his letters should be printed over his own name, provided the brands he weighed were also mentioned—upholding his first statements that light plates are being sent into the United States and that the practice will, unless discontinued, ruin the Welsh tin-plate trade in this country. He also offers proofs of the correctness of his weights from boxes of tin plate in his store. Concluding his letter, he says: "We had nothing but the kindliest feelings for the Welsh makers, and we called their attention to a piece of folly, hoping that they would take it in the right spirit and correct the evil. Instead of that, they try to bolster up the wrong acts of a few makers."

The State of Washington is recognized by those who live there as possessing great resources, promising a grand development. In Tacoma, its principal port on Puget Sound, there are already 50,000 inhabitants, and in the State at large 120,000. A correspondent writes that nearly $3,000,000 of building was done in Tacoma last year, and he is informed that still more is projected for 1893. Another writer discourses with enthusiasm upon that great inland sea, Puget Sound, with its hundreds of safe harbors, "so deep that an ocean vessel can sail up to its shores and make fast to the fir trees that grow to the waters' edge." The people who are building up the country are reputed to be of more than the average intelligence of new settlers.

THE WORLD'S FAIR.

The Actual Condition of the Exposition.

For the benefit of our readers who may be contemplating an early visit to the World's Fair at Chicago we have caused a thorough investigation to be made of the exact status of the work of preparation. This has been done by our own representatives, who have been uninfluenced in any way and have only sought to secure actual facts. There is no question that the Chicago exposition will far surpass, both in magnitude and splendor, any of the international expositions thus far held. It will, therefore, be unfortunate if a very large number of persons from distant sections of the country should visit it too early, and finding it in an incomplete condition should represent it to their friends and neighbors as disappointingly crude. The managers of the exposition have been obliged to contend with the most formidable obstacles and to overcome the most forbidding conditions from the very inception of the enterprise, not the least of which has been the very unfavorable weather of the entire month preceding the opening day. This is the period in which the grand work of two years should have come to a successful climax, the culminating point being completed buildings, completed exhibits and completed grounds. That they have been disappointed in accomplishing the work in the time specified is not to their discredit, and reproaches do not lie against them. They have done nobly, but they could not accomplish the impossible. No previous international exposition had opened its doors with every nail driven, every display in place, grounds in perfect order and contractors out of a job, hence Chicago could not reasonably expect a different order of things to prevail. Exhibitors will fail to ship their goods in ample season for installation, and a thousand little delays aggregate a formidable mass of confusion at the wind-up.

Chicago push is proverbial, but even Chicago push cannot prevail in a contest with the rest of the world and the elements combined. The preparations for the exposition are not complete in many respects, and it is only just to our readers that we should say so. While visitors even now will see much that is interesting and instructive, if they would get the full benefit of the elaborate preparations to be made for their entertainment they should wait until May has pretty well run its course. Details of the condition of the buildings and grounds the latter part of last week are as follows :

Department of Machinery.

In the Palace of Mechanic Arts the situation is unequivocally one of incompleteness. As regards the building and its several annexes there is much still to be done in the way of finishing up, though the strictly constructive portion of the work has been completed for some time. But experience teaches that this final finishing up process consumes, almost invariably, more time than was originally allowed for the purpose, and these buildings are no exception to the rule. The mere matter of clearing away debris, sweeping and furbishing, to place the whole in presentable shape for the inspection of visitors, is a work of days. Exterior painting, decorating and repairing of staff work damaged by the weather and the constant procession of teams to and from the interior, will require at least a week, though at the present tardy rate of operations it must spin out much longer, and until it is finished the unsightly scaffolding must remain. The grounds immediately surrounding the buildings are in a chaotic state of litter from the piles of gravel, old lumber and unused building materials, and on the south and east sides the ground is ankle deep in loose sand still to be graded and paved, and upon which the work has been entirely discontinued for some time past. In the interior, the lobbies, galleries and offices may be considered in as good condition as is possible, until the entire installation of exhibits is completed and the final cleaning up can be done.

The condition of the main floor is necessarily an uncertain quantity and must so continue until all machines are in place on their foundations, and all pipe and belt holes provided. Three of the original railroad tracks—situated about 4 feet below the floor level—are still uncovered for a distance of several hundred feet from the west end of building and cannot be floored over so long as delayed exhibits continue to arrive. This, judging from the large amount of totally unoccupied space alotted to exhibitors, will not be completed for an indefinite time, unless the exposition authorities shall fix or enforce the limit for their admission. While there can be no doubt as to the justice of such action its effects might be disastrous and result in many extensive gaps, seriously interrupting the continuity of the display and the wasting of valuable space which would have been taken gladly by other manufacturers who were desirous of making extensive exhibits. Judging from present appearances the condition of affairs in this department will require some very energetic work for several weeks to come in order to complete the installation of exhibits and the subsequent general finishing touches necessary to a creditable display.

Outside of the power and electric plant and a few other conspicuous exceptions, it is no exaggeration to say that the buildings are in a chaotic state, which would admit of but little satisfaction to pay for the difficulties of an attempt at a general inspection of exhibits. So far as this department is concerned it will certainly be a great mistake for those who can devote but a limited amount of time to the exposition to make their visit earlier than the latter part of June. The display, when completed, will be most magnificent and well worthy of the attention of all who may have the opportunity of visiting the fair, but it should be seen in its normal condition and not during the transition period.

The Transportation Building.

The Transportation Building, which is one of the very large buildings of the fair, and is intended to present a display of exhibits which will be attractive, not only to those interested in methods of transportation, but to the masses generally, is in comparatively good shape. The inclosures of the different exhibitors are well completed, and exhibits are mainly in such shape that a very few days will enable them to be put in proper order. The opening day may not have seen everything in trim, but not many days will elapse until this building needs no further touches to make it complete. The full-size model of the great steam hammer of the Bethlehem Iron Company looms up in the center of this building completely finished. Around it are a great variety of displays of all kinds of exhibits covering both land and water transportation. The annexes are full of locomotives and all kinds of passenger and freight cars, from the earliest type down to the most finished constructions of this modern era. The visitor to the Transportation Building will be repaid in a very short time for the trouble taken to see its exhibits.

Outside of this building the roadways are not inviting; some of them are in very bad condition, having been cut up by heavy traffic teams. It would seem as though a week or two of good weather and a great deal of very hard work would be necessary to make them presentable and insure visitors against wading through mud or suffering from clouds of dust. And yet it is remarkable how quickly work of this character can be done with the energy shown by the management. Passing to the north entrance in the Mines and Mining Building in the morning a great waste of rough roadway was crossed, which in the afternoon was found to be covered by a smooth sheet of asphalt which had been placed in position and smoothly rolled during the short intervening period. Looking at such achievements it is not safe to indulge in unfavorable predictions as to length of time necessary to get the roadways in good shape.

Administration Building and Terminal Station.

The Administration Building is practically completed. This is the show building of the group, having been planned on a more elaborate scale of ornamentation and for a greater display of architectural effect than any of the others. Such slight finishing touches were being added last week as were of no special moment, but more in the nature of house cleaning and brightening up. The great dome which covers the interior of this building, starting from the ground floor, is finished and excites the admiration of all who see it when they gaze upward and examine the magnificent fresco work.

The Terminal Station within the grounds, intended for the accommodation of excursion trains on any of the railroads running into Chicago, is located a short distance east of the Administration Building. It is completed and ready for the accommodation of World's Fair traffic. Between this building and the Administration Building is a broad plaza which will be macadamized, the work now being well under way. So quickly is this done by a very large force of men who have all the necessary appliances for rapid work, including heavy steam rollers, that large sections are completed in hours instead of days, as is usually the case. One of the worst pieces of roadway in the grounds is that which extends north of the Administration Building between it and the Mines and Mining Building. This looks as if it would not be presentable until after all the heavy hauling ceases and several days can be taken for its complete reconstruction. This space is rendered the more uninviting by the erection of some pavilions for various purposes, which are as yet uncovered with staff and consequently present a forlorn appearance.

Mines and Mining.

In the Mines and Mining Building quite a number of exhibits were finished and ready for inspection last week. Among these may be mentioned that of Stumm Bros., the comprehensive display of New South Wales, the exhibits of the Cambria Iron Company, the Solid Steel Company, Wm. Jessop & Sons, the Gates Iron Works and the States of Missouri and Minnesota. The exhibit of Stumm Bros., who are prominent German manufacturers, was described to some extent in these columns about a month since. It occupies a very conspicuous position, and is all the more conspicuous by reason of the non-completed state of the exhibits surrounding it. The Cambria Iron Company make a very creditable display of their products, a prominent position being given among them to the original Kelley converter. Chief Skiff has pushed the work of installation in this building with unceasing vigor, but despite his utmost exertions the building will not be in good shape for certainly two or three week. Some of the exhibitors have but recently begun to erect their pavilions, and the aisles were

blocked by packages of goods, which could not be put in place until after the pavilions were ready to receive them. The cabinets in the galleries intended for mineral specimens were only partially completed last week, and the work of unpacking, placing and arranging the specimens will certainly take days, if not weeks of time. It is likely that everything will be in good shape here at an earlier day than is at present deemed possible, because in every direction work is being prosecuted with energy and everybody is evidently hurrying to make up for lost time.

The Main Building.

The great building devoted to Manufactures and Liberal Arts was last week a scene of almost indescribable confusion. Everywhere there were crowds of workmen bustling and hurrying, who were attacking huge piles of merchandise, packing boxes and all sorts of building material, trying to get matters into good shape, but making such slow progress that a day seemed to count for very little in getting things in good condition. Piles of lumber obstructed the aisles, innumerable pavilions were only in the early stages of construction, and in very few parts of the building could an idea be obtained as to the character of the exhibits to be made in that particular section. Some of the exhibitors have their pavilions and exhibits in perfect shape. Conspicuous among these are the English, German, French and Belgian sections. Our own people seem to be the most dilatory. Exhibits from Chicago houses were only arriving the latter part of the week, the people nearest the fair apparently having delayed their work the longest. The Russian pavilion, however, has just been begun. The section devoted to stoves and house furnishing goods would have been difficult to find had it not been for the huge pavilion of the Michigan Stove Company, built in the form of a cooking stove, standing 25 feet high and 30 feet long, which makes a striking landmark in the general chaos. The visitor who enters this building this week and expects to see a complete collection of exhibits will be very much disappointed. Two weeks at the very earliest will be required, and perhaps more time than that will be necessary from present appearances.

The Agricultural Building.

The Agricultural Building, which is another of the great buildings of the fair, presents a mere promise of what the display in it will be. Exhibitors were actively at work on their pavilions, but while some of these were completed and in full readiness for the opening day, others were comparatively unfinished and numbers of them had just been begun. Packing boxes filled up the aisles and in many cases were piled so high as to cut off the vision over a great part of the area. A month would seem to be none too much for the proper arrangement of exhibits in this building.

The Electricity Building.

In the Electricity Building, in which there are comparatively few exhibitors, who were therefore expected to get their exhibits in good shape at a very early day, much still remains to be done and the display could by no means be considered nearly ready. Packing boxes were as conspicuous here as in the other buildings, and days, if not a week or two, would be needed to enable the exhibitors here to get everything in presentable shape.

Other Buildings.

A ramble among the various buildings located in the north end of the grounds shows that much work yet remains to be done before they will be in a finished condition. The external staff work of Horticultural Hall plainly shows the effect of last winter's storms. In some places below the window belt the staff is broken away and must be replaced. Workmen are engaged on the exterior of the building making repairs. The staff is streaked with dirt and requires painting. The floral display in the rotunda is partly finished, workmen being yet engaged in placing plants and decorations. There are few exhibits in the galleries, as workmen are finishing the decorations. In the southeast part of the building the floral exhibit is about completed, while in other parts very little has been done at installation.

The Public Comfort Building is in an unfinished condition. The walls are only partly covered with staff, while floors are being laid and partitions plastered.

Puck Building shows a finished exterior. Printing presses are in position on main floor, but no exhibits are in the gallery. The staging is yet up for decorating the interior. The exterior of the Woman's Building presents a fair appearance, as do the surrounding grounds. An inspection of the interior shows that few of the booths are finished, and hardly any exhibits are in position in the Main Building, booths, or gallery.

While the Illinois Building is finished, few exhibits or decorations are in position. The grounds about this building are being improved. The exterior of the Indiana Building is being finished, and the same can be said of the interior and grounds. Old Point Comfort Building presents an unfinished condition, the scaffolding yet being up and men at work finishing the exterior. The roof of California Building is being finished. There are a few exhibits in the gallery, but none on the main floor. The grounds about this building are in an unfinished condition. The Wisconsin Building and grounds are completed. The interior of the building is finely finished in hardwood, but not furnished. Colorado presents a finished building, but not furnished. The grounds are being put in shape. The Michigan Building is in good condition and finished. The interior is not furnished. The Washington building is finished and ready for furnishing. The South Dakota Building is finished, and the grounds are being put in order. Minnesota presents a finished building, the interior being furnished and the grounds in order. The exterior and interior of the Louisiana Building are finished, but not furnished; a force of men is at work on the surrounding grounds. The exterior of the Missouri Building is being painted, as is the interior. The grounds are in an unfinished condition. Pennsylvania presents a finished building and grounds. The New York Building is in an unfinished condition, as are the grounds. The staff work shows the effects of the weather and requires painting. The exterior and interior of the Massachusetts Building are in good shape, while the grounds are unfinished. The Vermont and Maine Buildings and surrounding grounds are in an unfinished condition. The exterior of the Ohio Building is being painted. The interior is finished and ready for furnishing. The grounds are in an unfinished condition. The exterior of the New Hampshire Building is finished and the interior partly so, but the grounds are unfinished.

The Connecticut, New Jersey, Maryland and Kansas buildings and grounds are finished, and the buildings ready for furnishing. The Iowa Building is finished externally and the interior about finished. The decorations in the main room are about completed, but the grounds are unfinished. The Rhode Island, Delaware, Virginia, Montana, Utah and West Virginia buildings are finished ready for furnishing, but the grounds are not improved. The Idaho Building, which is built of stone and logs, is about half completed. The exterior of the Oklahoma Building is finished, interior partly so, but no improvements have been made to the grounds. Florida presents a building the exterior of which is finished, the interior partly so, while the grounds are mostly finished and ornamented with tropical plants. The Arkansas, North Dakota, Nebraska and Kentucky buildings are finished externally and interiors being finished. The grounds are unimproved. The staff work of the Texas Building is being completed, while the interior and grounds are in an unfinished condition.

The exterior of the Art Galleries shows the effect of the weather, as the staff work is discolored, although workmen are engaged in making repairs. A coat of paint is required to make the buildings presentable. The entrances to the buildings are in an unfinished condition, as are the surrounding grounds. An inspection of the interior shows workmen engaged in decorating walls and installation of exhibits. Among the countries most advanced in installation are the United States, Germany, Great Britain, Netherlands and Austria.

The staff work of the Fisheries Building is badly discolored, and anything but white. Grounds are in a fair condition. Only part of the exhibits are in place in the Main Building, and the same can be said of the west wing. In the east wing the aquaria are in place and the entire exhibit about completed.

The exterior walls of the Government Building are being painted and will present a handsome appearance when finished. The exhibit in this building is practically finished in most departments. The complete arrangement of the different Government departments with their independence of any outside force has enabled them to go ahead with their installation regardless of other exhibits, hence their advanced condition. In the National Museum Department most of the exhibits are in position, and the ceiling is gayly decorated with numerous flags. In the Departments of Justice and State pictures are in position on the walls and cases are partly filled. The Department of Agriculture is only partly finished, many packing cases being on the floor to be opened. In the Fisheries pictures are hung on the walls, and about two-thirds of the cases are filled with exhibits. In the Patent Office Department the cases are filled with exhibits and a good showing is made. The Geological Survey relief maps are in position and the cases are well filled with specimens and instruments. The Bureau of Education cases are filled with models of school desks, and the shelves with books. Photographs, examples of school work and plans of school houses are all in position. The large globe is not finished. In the Post Office Department is found the World's Fair Post Office, which is in running order; also a model postal car. While many cases are filled with exhibits, much remains to be done. In the Coast and Geodetic Survey very little has been done toward the installation of exhibits. Numerous cases are filled with Smithsonian specimens, yet much remains to be done. In the rotunda of the building the large redwood tree is in position and the decorations are completed. The staging is being removed. On the east side of the building a number of large guns are in position.

The staff work of the French Colony Building is nearly finished and some work is being done to the interior, while the grounds are unfinished. The Ceylon Building is not yet inclosed, although much fine building material is on hand. The north half of the German Building is being finished and decorated and the interior exhibits are being placed in position. The other part of the building is unfinished. No improvements have been made to the grounds. The Haytian Building is well advanced, as the exterior and interior

are about finished, but no exhibits are in place or improvements made to grounds. The New South Wales Building is finished, but no exhibits are in place and the grounds are unimproved. Victoria House is finished but the grounds are not. The same can be said of the Canadian Pavilion. The East India Pavilion has the staff work partly finished and the interior the same. Some exhibits are in place and the grounds are unimproved. The exterior and interior of the Swedish Building are being finished, but the grounds are unimproved. The framework of the Venezuela Building is up and being covered with staff. The Turkish Building has the exterior finished and the interior partly so. Some exhibits are being placed in position. The grounds are unimproved. While the exterior of the Brazilian Building is being covered with staff, little work has been done to the interior. The exterior of the Guatemala Building is being covered with staff, also the inner court. The frame work of the Colombia Building is up and the staff work just commenced. The Costa Rica Building is about finished, but no exhibits are in the cases and the grounds are unfinished.

Prize Competitions

$25.00.

Prize Competition No. 23.

In this series of competitions we are desirous of discussing subjects which will be of practical interest to the trade, with a view to drawing out suggestions and information which will be of service. We are desirous of hearing from the trade in regard to topics the discussion of which would be of interest to them, and we accordingly announce as the subject for Prize Competition No. 23:

Three or More Subjects for Prize Competitions.

We do this, hoping to receive from the trade at large many topics which might advantageously be discussed in this way. Many merchants or clerks who may not have the time to discuss trade questions can obviously suggest them, and we shall esteem it a special favor if our readers will mention freely any subjects which seem to them of trade interest.

Some of the subjects which have already been announced have been suggested by our readers.

This competition will remain open until May 27, 1893.

The following prizes will be awarded:

First prize	$12.50
Second prize	7.50
Third prize	5.00

The prizes will be awarded for answers which in the judgment of the committee of award suggest three or more topics most suitable for discussion in this series of prize competitions.

We reserve the privilege of extending the time on any competition in case the contributions received are not of sufficient number or merit for the committee to award prizes. These competitions are open to every one, and it is hoped that there will be a general response from business men. We shall have the privilege of publishing any or all of the contributions received.

Replies are to be received not later than May 27, 1893. They should be addressed as follows:

DAVID WILLIAMS,
96–102 Reade street,
New York.
Prize Competition No. 23.

The committee to whom the contributions in Prize Competition No. 9 were referred have awarded the prizes as follows:

First Prize of $50 to Ross F. Rainey, Pittsburgh, Pa.

Second Prize of $25 to W. D. Parlin, Natick, Mass.

Third Prize of $15 to John F. James, Roanoke, Va.

Fourth Prize of $10 to Daniel P. Holmes, Norwich, N. Y.

Other Competitions which have closed are now in the hands of the Committees of Award, who are giving careful attention to the claims of the different contributions. From the number of these and the evident merit of not a few of them, we are assured that a great deal of valuable information and suggestion will be put at the disposal of the trade.

The Weekly Prize Competitions noted below are now before our readers and remain open until the dates named:

No. 20. Closing May 6.
A Reliable System for Securing the Correct Charging of All Goods Sold on Credit.

No. 21. Closing May 13.
The Safety Line in Credit Business.

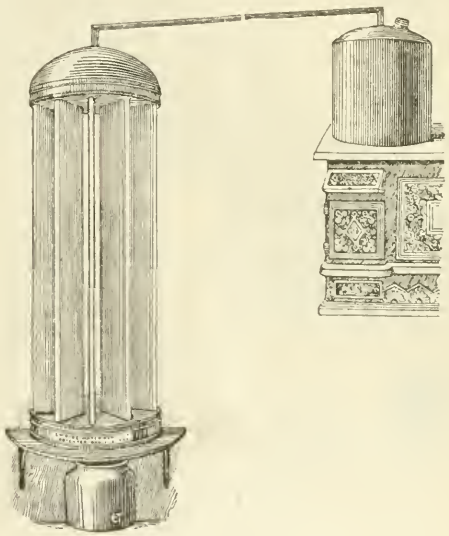
No. 22. Closing May 20.
The Best Manner of Presenting and Collecting Book Accounts.

No. 23. Closing May 27.
Three or more Subjects for Competition.

Another subject will be announced in our next issue.

Empire Water Purifier.

Pure water has been declared by an eminent physician to be that which comes nearest to a universal remedy for all diseases, and its value is being more generally recognized. It is claimed for the Empire water purifier, illustrated herewith, that it will furnish absolutely pure and wholesome water. The apparatus consists of a block-tin vessel—the boiler or vaporizer—which can be used on any kitchen range. This boiler is connected, as shown in the cut, with a condenser or purifier of novel form. It is a copper apparatus consisting of a hollow dome and base connected by a number of upright flat tubes. The mode of operation is simple. The steam from the boiler passing through the connecting tube into the dome condenses and falls downward through the flat tubes into the hollow base, cooling gradually in its descent. It is discharged from a tap at the base into the vessel placed to receive it. The purifier is made of copper coated inside with tin, the connecting pipe being also of copper, brazed, and tinned inside, exposing no metal which could be acted upon by the steam or water. All parts are readily disconnected, and as the purifier weighs but 8 pounds, it can be easily shifted about and removed when not required. It is also easy of operation; and can, if desired, be connected with the spout of any ordinary kettle. The capacity of the apparatus is 1 gallon each hour. Any description of water, even that of the sea, can be treated in this manner. This would adapt the purifier for use in sailing vessels where condensing facilities do not exist. The Empire Water Purifier is handled by the Empire Pure Water Supply Company, 203 Broadway, New York.



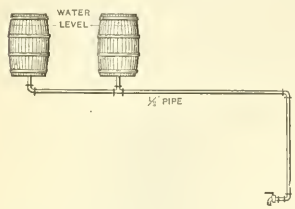
Empire Water Purifier.

The following recipe is said to make an excellent anti-rust paint for bright steel goods: To 1 gallon of gasoline add 6 ounces of pulverized resin, 3 ounces of pulverized borax and 4 ounces of pulverized alum. By adding 1 pound of fine ground black lead with 2 ounces of lampblack, an excellent stove polish is said to result. This polish is applied to the stove with a soft brush and polished when dry.

THE LETTER BOX.

A Question of Water Pressure.

From J. S., *Watertown, Conn.*—Please decide the following question in *The Metal Worker:* A connects two barrels of water as shown in Fig. 1; B claims that more pressure is to be obtained if the barrels were connected as shown in Fig.



A Question of Water Pressure.—Fig. 1.—*A's Method of Connecting Barrels.*

2. Does A get more pressure by having both outlets on the bottom than B with one outlet, as shown in Fig. 2?

Answer.—We assume that the water level in both cases is the same, and that the faucet is the same distance below the water. This being so, the pressure at the faucet will be the same in both cases.

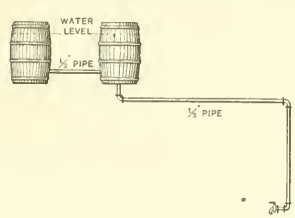


Fig 2.—*B's Method of Connecting Barrels.*

The pressure of water depends upon the head—that is, the hight of the surface above the outlet—and is not affected by the volume of water or the connection between the different reservoirs.

To Clean Out Smoke Pipe.

From C. H. M., *Otio, Mich.*—Can you tell me what will clear the smoke pipe of a furnace in which soft coal is burned of the excessive deposit of soot? The pipe fills up so in about three or four weeks time that the furnace will not draw.

Note.—The probable cause is an insufficient draft, due to a chimney that may need cleaning or which is smaller than is required to carry off the smoke quick enough to get the soot out of the top of the chimney. A general experience is that soft coal requires a larger smoke pipe than is found to be ample with hard coal. If the collar is 7 inches on a hard coal furnace many experienced furnacemen taper the first piece of pipe immediately up to 9 inches and run the larger size to the chimney and make a similar proportionate increase in size whatever the collar may be. This increase in the horizontal pipe carries the enormous quantity of smoke, made by a soft coal fire under some conditions, to the chimney quickly, where the rapid up draft disposes of it satisfactorily. If the furnace has a diaphragm in it to aid in realizing the heat from the smoke and gases, it should be cut off more or less when soft coal is used to permit their more rapid passage to the pipe. It is quite a common thing in sections where soft coal is used to put straw in the furnace and burn out the pipe, but this is only a temporary relief and must be applied with care. This suggestion may be most satisfactory to our inquirer, particularly if the pipe in question is good, but when it is to be renewed it should be given a generous increase in size.

Corrugated Fire Boxes.

From B. B., *Amherst, N. S.*—Please inform me whether a plain or a corrugated fire box for a wood furnace is the better form.

Note.—The advantage gained by corrugating a fire box is the increased heating surface, which is an important feature in all work where heat has to be extracted from the fire and has to be given to the air or other medium. An objection to this form is that the corrugations are lodging places for ashes and dirt, which act as non-conductors. If cleaned regularly, however, there is no reason why the deposit should seriously interfere with the heating power of the furnace.

Placing Rivets in Punched Holes

From M. T. C., *Riverside, Cal.*—Which is the proper way to place a rivet in a hole punched through light iron? Should the head of a rivet be on the burr side or on the side the hole was stamped from?

Answer.—The usual practice is to place the head of a rivet on the burr side if it is desired to flatten down the rivet so that it will be flush with the iron, as, for instance, on the small end of an elbow or a collar which is to fit into the large end of another elbow or pipe. The head of a rivet when put on the side from which the hole was started in punching can be drawn up tight against the iron, making a smooth, neat finish for the large end of elbows, pipes, collars, &c. Rivets placed in this manner, after being drawn up, are then hammered down and finished with a cup or cone-shaped rivet set on the out or upper side of the material. This leaves a smooth under side, which will not obstruct its ready fitting over another piece, which would be the case if the rivet was not perfectly flush on the under side or had been placed with its head against the burr of the punched hole. If it is desired to join two pieces of light material together, never place the iron or punch the rivet holes so that the rivet heads will come on the burr side, as the action of drawing, upsetting and heading the rivets tends to stretch the iron considerably. This trouble is not encountered if the heads of rivets are on the side from which the rivet holes have been started in punching. Another way is to have the rivet holes large enough, so that after they have been punched the burrs can be flattened down. By this method it makes no difference on which side the rivet is placed with its head. One disadvantage of this treatment is that it requires the utmost care to have the holes all come right and match each other. The operation of flattening down the burrs also tends to stretch the material to some extent, which is by no means a desirable feature in some classes of work.

Sharp Criticism on Boiler Connections.

From S. H. D., *Watkins, N. Y.*—Noticing the cut of the Perfection Water Heater in *The Metal Worker* of April 29 I wish to say that I think the manner of connecting the hot water service to the circulating pipe is wrong. The hot-water pipe should never be taken from the circulating pipe or the water will be drawn from the circulating pipe and not from the top of the boiler, and cold water will soon come from the bottom of the boiler through the pipe to the water back or gas-heater and will not be hot enough, from passage through them, to be satisfactory. Having changed a number of such connections that were unsatisfactory, with good results, I feel that I am right in speaking my experience positively. There is no objection to connecting the circulating pipe to the top of a boiler if all of the other connections are properly placed. Connect the cold water supply at the side opening in the boiler near the bottom, using one of the top openings for hot service, getting rid of the air at top of circulating pipe by an air valve or a vent to the tank, if there is one, and it will be all right.

Note.—Such an outspoken opinion and criticism, if received with a view of testing its correctness and making the result profitable, can only result in good to all interested. Many good plumbers differ on the point at issue, making it worthy of close investigation. Illustrations and comments on the same subject will be found in *The Metal Worker* of February 25, March 11 and March 25, 1893, giving question and answer and other comments.

In a recent article in the Letter Box "J. C. F.," Williamsburgh, Ohio, inquired for a sliding damper. We have received from W. B. Wilkinson, 210 Water street, manager of the New York branch of the Howard Furnace Company, a circular illustrating and describing Read's Patent Regulating Check Damper made by Josiah M. Read, 63 Blackstone street, Boston, Mass., and which the Howard Company carry in stock.

Time Report Cards.

From M. & T., *Clinton, Ia.*—We apply to the Letter Box for a good workman's report card, one that can be printed on a postal card so as to be mailed in every night when a workman is off or on a jobbing tour or engaged on an out-of-town job. To be complete for our use, it should be so that the time and material used and the name of the customer could be easily recorded. A card for each day, so that by providing the workman with a week's supply, the record of each day can be given in each night in person or by mail.

WORKMAN'S TIME REPORT.

For day ending.....189

Men must inform themselves on what portion of work they are engaged, and keep time carefully, under penalty of dismissal.

Time spent.	Description of work and account of materials.

Memoranda.....

Workman's name.....

Customer.....

WORKMAN'S REPORT.

Name, *Thomas Cooper.* .....Day Ending *April* 1, 1893.

Hours spent.	Customer's name.	Kind of work and material used.
1	J. Brown	Mending roof. Half pound solder and two sheets of 20 x 28 tin.
2	K. Smith	Cleaning smoke pipe. Two joints and one elbow, 7-inch, galvanized.
2	W. Jones	New waste pipe in sink. Three feet of $1\frac{1}{2}$-inch lead pipe.
2	Mary Thompson	Changing gas pipe. One pound fittings, one No. 2 double-joint bracket.
2	Saml. Robinson	Repairing copper pump. One bottom valve, new leather one upper.
1	Sara Johnson	One damper in smoke pipe, 6 inch.

Note.—One of the accompanying report cards may answer the requirements, or may suggest something suitable. The particular work done on any day can generally be recorded in full on the space which either card affords.

Metal Siding.

From L. F. S., *Jasper, Ind.*—Will you or some of your readers kindly inform me how rock-faced or galvanized clapboards will do for siding? How long will they last without paint? How long will paint last on them?

Note.—Galvanized iron has been found a first-class covering for the sides as well as the roof of the building. It is easily adapted to the various shapes of the building, and when carefully put up is durable and presents an attractive appearance. Its lasting qualities without paint depend somewhat on the climate and location as to dampness, but that it will last a long time can be readily seen by noting buildings where galvanized work has been exposed to the weather for a number of years. The change in color and unattractive appearance when exposed for a time suggests strongly the use of good paint, when not only the appearance but the durability is increased, so that it compares favorably with the materials in general use for the same purpose. The paint should be in two coats, and if of good quality, well put on, it will last as long as if put on any other material subject to the same exposure. The advantage of an iron siding in case of fire is so apparent that there is no restriction in its use in cities where wood would not be permitted.

Size of Pail for Stamped Cover.

From H. D.—Will the readers of *The Metal Worker* inform me if there is a definite rule for obtaining the length of bodies for pails or buckets when stamped covers are used? Supposing a pail is to be made for a stamped cover $9\frac{1}{4}$ inches in diameter, what should be the diameter or circumference of the body so as to fit the rim, a No. 10 wire being used for body and medium-sized burr on rim and cover?

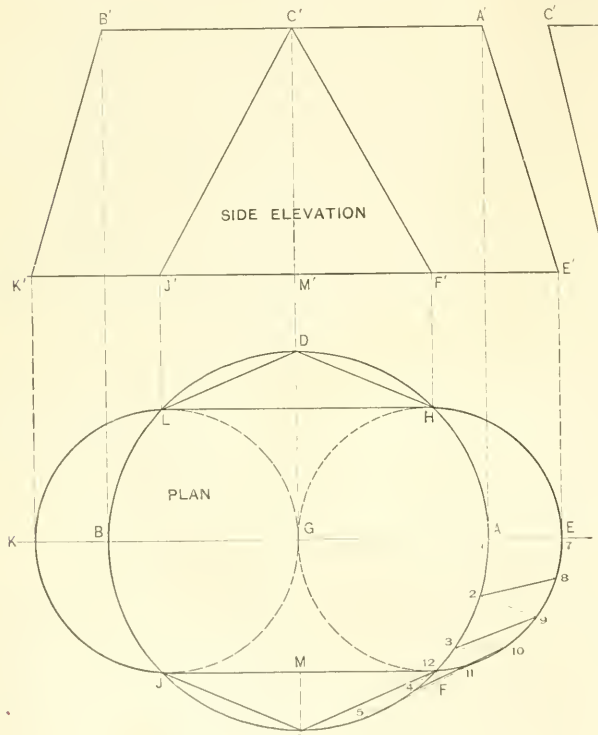
He Can Make Enameled Brick.

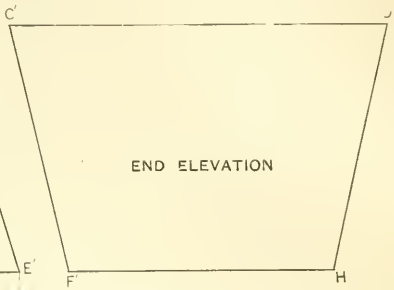
For 32 years, says a Chicago paper, American brick makers have been trying to make a true enamel surface to brick. If they will now visit Chicago they will find an establishment where the work is being successfully done. Heretofore all enameled brick have been imported from England at a cost of $125 a thousand. For years there has been a glazed brick made which cracks and peels off. Two years ago S. Linderoth built a factory at Fifty-second and Wallace streets and began experimenting with the clay and glazing. He now announces the success of his labors and claims to be able to furnish a purer enamel than the imported article. He ascribes his success to his knowledge of chemistry, which enabled him to discover the proper qualities of clay necessary. Capitalists are now being interested in the enterprise. "There are only six such concerns in England," said S. Linderoth. "The secret has been handed from father to son for centuries. Professors have been sent from America to Europe to work in the yards, but could not discover the process. Our clay has been different and the study has been a hard one. I believe the enameled brick can be made here much cheaper than abroad. I have had offers from several firms, but I believe there is a fortune in the discovery and will try to keep it for myself."

THE TIN SHOP.

Pattern for Article Round to Oblong.

From T. E. H., *Green Bay, Wis.*—I would like to see a method published in *The Metal Worker* for obtaining the pattern of a transition from round to oblong. In the plan, Fig. 1, B D A C represents a 36 inch round pipe that is to join the oblong K L H E F J The oblong is to receive K and K G C. Then the pattern for one of these parts will answer for the others. The method to be adopted in describing the pattern will be that of triangulation, and for this purpose divide A C of plan of top into any convenient number of equal parts, as indicated by the small figures 1 to 6. Also divide E F of plan of base into the same number of equal parts as was A measured on the finished article. To obtain a diagram of triangles represented by solid lines in plan, lay off at any convenient place the line N O, Fig. 2, equal to the straight hight of article, as shown by M′ C′ of elevation. From the point N, and at right angles to O N, draw the line N P, extending it indefinitely in the direction of P Measuring from N, set off





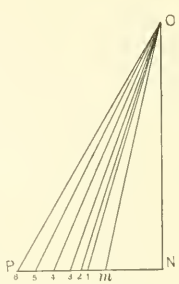


Fig. 2.—Diagram of Triangles Corresponding to Solid Lines in Plan.

Fig. 3.—Diagram of Triangles Corresponding to Dotted Lines in Plan.

Fig. 1.—Plan and Elevations.

PATTERN FOR ARTICLE IN SHAPE ROUND TO OBLONG.

two 25-inch round pipes, as indicated by K L G J and G H E F. In the elevation, B′ A′ represents the 36-inch round pipe, and K E the part of oblong corresponding with K E of plan. J C F is a triangle connecting base with top, as shown in plan by J F C and L D H. In the end elevation D C′ corresponds with the diameter of large pipe, as shown in plan by C D or B A. F H of end elevation also corresponds with F H or J L of plan.

Answer.—An inspection of the plan will show that the part of article contained in C G E, as represented by C M F A E, is similar to parts contained in E G D, D G C, as indicated by the small figures 7 to 12. Connect the points in A C with those in E F, as indicated by the solid lines. Thus connect 2 with 8, 3 with 9, 4 with 10, &c. Also connect the points in A C with those in E F, as indicated by the dotted lines. Thus connect 1 with 8, 2 with 9, 3 with 10, &c.

Our object will be to construct triangles whose bases are equal to the length of lines drawn from points in E F, and whose hypotenuses will give the distances from points in A C to points in E F as if the length of solid lines drawn between A C and E F of plan. Thus make N 1 of diagram equal to 1 7 (A E) of plan; N 2 of diagram equal 2 8 of plan; N 3 of diagram equal to 3 9 of plan, &c. From the points thus established in N P draw lines to O, as shown. Then the hypotenuses O 1, O 2, O 3, &c., correspond to the width of the pattern measured between points in A C and E F of plan, as indicated by the solid lines. In the same general manner we construct the triangles shown in Fig. 3, which correspond to sections on the

dotted lines of plan. Q R corresponds to the hight M C of the elevation, and Q S is drawn at right angles to the perpendicular Q R. On Q S, measuring from Q, set off spaces corresponding to the length of the dotted lines drawn across the plan. Thus Q 1 corresponds to A 3 of the plan, and Q 2 corresponds to 2 9 of the plan.

From the points thus established in S Q draw lines to R, as shown. The hypotenuses of the triangles in Fig. 3 are equal to the width of the pattern measured between points connected by the dotted lines in the plan.

We can commence the pattern at C M or A E of plan, as may be convenient. In the present instance we will commence at C M. Then at any convenient place, as T U in Fig. 3, draw a line equal in length to O *m* of diagram of triangles in Fig. 2. The distance O *m* is the same as F' C' or H' D' of end elevation. With U of pattern as center and M F (M 12) of plan as radius describe a small arc (V), which intersect the hypotenuses of the triangles in Fig. 2, corresponding to the solid lines in plan; and the stretchout of F E for the distance between points in V W of pattern. Trace lines freehand through the points in T X, V W, and draw X W. The T X W V U is the pattern of part of article shown on plan by C M F A E. The part of pattern represented by T U V' W' X' can be obtained by the same process or by duplication.

The Tinware Trade.

In speaking of the many changes which have occurred in the making and marketing of tinware since he first became connected with the business, Wm. Geuder of the Geuder & Paeschke Mfg. Company, Milwaukee, Wis., incidentally referred to the item of wash boilers as an apt illustration of his point. Said he: "It is not so very many years ago that the average tinner and hardwareman made all his pieced tinware by hand and prided himself, with much justice too, it must be admitted, on the quality and workmanship of

fied to and corroborated by many eye witnesses, will bear favorable comparison with those of their earlier fellow craftsmen, but their ranks are becoming thinned out more and more by the steady advance of factory-made goods, and soon it will be as much of an oddity to see a hand made wash boiler as it is now to see small wares produced in that manner.

"Where factories supplied only a comparatively small proportion of the wash boilers sold not longer than five or six years ago, the demand has become so large now that we are all obliged to produce enormous quantities of goods in addition to our other lines, and there are several firms in the country who devote themselves exclusively to the boiler business and doubtless find it profitable to do so."

Furnace Pipes in Chicago.

The following extracts from the building ordinance passed by the City Council of Chicago, March 13, 1893, sent us by a correspondent, may be of interest to many of the readers of *The Metal Worker*. It will be observed that all register boxes

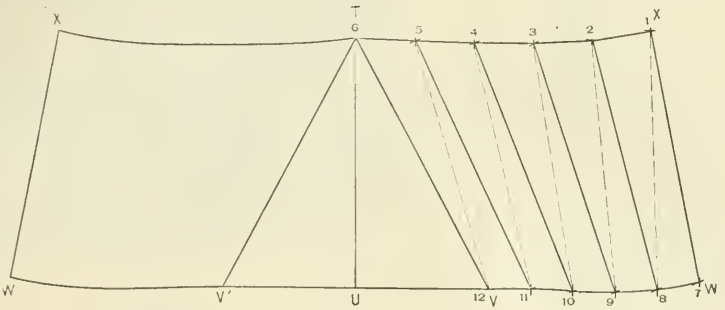

Fig. 4—One-Half of Pattern.

PATTERN FOR AN ARTICLE IN SHAPE ROUND TO OBLONG.

with one struck from T of pattern as center, with the space O P of Fig. 2 as radius, thus establishing the point V of pattern. Draw U V T. Then U V T of pattern is represented on plan by C M F. From T of pattern as center, with the space C 5 of plan as radius, describe a small arc (5), which intersect with one struck from V of pattern as center and radius R S of Fig. 3, corresponding to the dotted line 5 12 of plan, describe another arc intersecting the one just drawn, thus establishing the point 5 of pattern.

With V of pattern as center and 12 11 of plan as radius describe a small arc, which intersect with one struck from point 5 of pattern as center and O 5 of Fig. 2 as radius, thus establishing the point 11 of pattern. With point 5 of pattern as center and 5 4 in C A of plan as radius strike a small arc, which intersect with one struck from point 11 of pattern as center and R 4 of Fig. 3 as radius, thus establishing the point 4 of pattern. Proceed in this manner, using the stretchout of C A for the distance between points in T X of pattern; the hypotenuses of the triangles in Fig. 3 corresponding to the dotted lines in plan;

what he produced. The establishment of factories and the introduction of labor-saving machinery, however, by which the production of these goods in large quantities and at extremely low prices became possible, made it unprofitable for him to continue making his own wares, and now he sorts up his stock of tinware just as he does all his other lines when the representative of his favorite manufacturer or jobber calls on him.

"There is one item especially, that of wash boilers, which was dear to his heart, and to the making of which with his own hands he clung with the utmost tenacity, many even to this day buying all their other ware and making their boilers. There is a certain romantic halo thrown about this one item which appeals very strongly to the sentimental nature of the disciples of our craft. How well do we all remember listening with awe and secret envy to the narrator of the exploits of some venerable tinker, who in the good old days when the shear, stake and hammer were his only helpmates, and when such innovations as stamped bottoms and covers were still slumbering in the innermost recesses of the inventor's brain, had taken the tin out of the box, made up his bodies, made his own pits by hand and had finished up anywhere from 21 to 36 boilers in ten hours, without exerting himself the least little bit.

"And even to this day there are prodigies among us whose achievements, testi-

are to be made double, and the frames bedded in plaster of paris:

SEC. 146. Where pipes are used for the distribution of hot air in buildings, such pipes must be made of metal and double. The space between the two metal pipes shall be at least ½ inch and the two pipes shall be kept apart from each other by the insertion of metallic separators extending all around such pipes at distances of 3 feet apart, while the interior of the main pipe is to be provided with braces, one for every 3 feet in length of the pipe. Such pipes are to be made with air-tight joints and to be securely fastened to the partitions through which they pass.

SEC. 147. The openings in the floors for hot air registers shall be surrounded with borders of incombustible material not less than 2 inches wide, and firmly and securely set in place and bedded in plaster of paris. The register boxes shall be double, the distance between the two thicknesses of tin being at least 1 inch.

Where the air conveyed through pipes is heated in an ordinary hot-air furnace, or in any other apparatus by direct contact of the air with a fire box, the material used for these double ducts, pipes and register boxes shall be bright tin, and the joints shall be double seamed, but not soldered.

Where the air is heated by contact with hot water or steam pipes, any other sheet metal may be used for the pipes, and the use of double pipes is not obligatory.

STEAM AND HOT WATER.

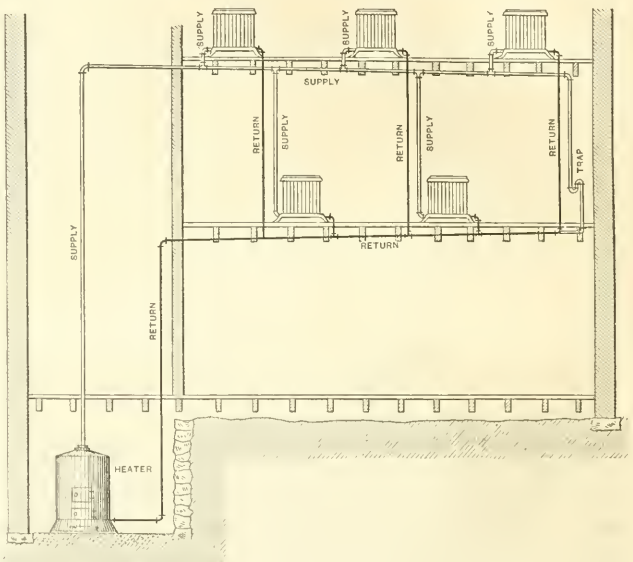
Radiator on Boiler Level.

From L. M. W., *New Haven, Conn.*—In your answer to "M. E. R.," Nashville, Tenn., in *The Metal Worker* of April 1, in my opinion you impress him that it is a difficult undertaking to heat a radiator on the same level as the hot-water heater rather than explain what must be observed to do it successfully. You fail to provide an air cock at the highest point, and you omit to provide an expansion pipe leading from the return somewhere near the heater to a tank located above the highest point in the system, which are very essential. If any one who attempts a similar job will, by test, see that there is an absolute and gradual rise in the pipes all of the way to the point where the return begins, and is equally careful to see that there is a gradual decline in the pipes running back to the heater, he will find no difficulty in driving any air that may be in the pipes to the highest point, and by locating an air cock there to be opened to let the air out, very little trouble will be found in securing a good circulation of water.

Steam-Heating Job.

From A. & B., *Burlington, Vt.*—Some time since we put a low pressure steam job in a building, the back part of which extends a long way over a cold open shed with no cellar under it. We were obliged to do the piping in a peculiar manner and it works very well. We inclose a sketch of the general run of supply pipes, but have not drawn in all the details. We desire the opinion of an expert upon this plan, including the trap, and wherein the arrangement of pipe could be improved without making a one-pipe job of it. There is a hall the whole length of this back extension in each of the two stories, but we could not run the pipes through the hall on account of the doors, and we could not place the supply under the floor with the return and get proper grade without cutting away too much of the joists.

Answer.—We are of the opinion that the trap on the drip pipe from the end of the main steam supply is of no use to the apparatus. It is placed by the fitter to prevent the steam from passing into the return pipe, yet no provision has been made for preventing the steam from passing through the first radiators connected to the steam and return mains and feeding into all the other radiators through the return pipe. There should also be drip pipes from the end of the down feed pipes to the radiators so that the condensation can drip out when the valve on the radiator is closed. As now arranged the valve on the radiator being closed for any length of time the down feed pipe will fill with water, lowering the water line in the boiler and causing a hammering noise when the valve is opened to feed steam to the radiator. In heating up this apparatus the steam will flow up through the main steam-supply pipe and feed into the first radiator, passing through it into the return main and feed from the returns into the radiators, causing the radiators to be air bound in the center, and it will take a long time to cause a complete and perfect circulation with low-steam pressure. The best way to have placed this apparatus would have been to run the main steam and return pipes as they now are, leaving out the trap on the end drip pipe. The returns from the raidiators should be run about 1 foot horizontal before they are connected to the main return. In this pipe place swing check valves, which will prevent any steam passing into the radiator from the return pipe, also drip each down feed pipe into the return. There should also be placed on the drip pipe, from the end of the main steam main and in the main return pipe above the water line at the boiler, automatic air valves to remove the air from the returns. If the radiation is connected up, as explained above, there will be a complete circulation throughout the apparatus without any pressure on the boiler.



Steam-Heating Job.

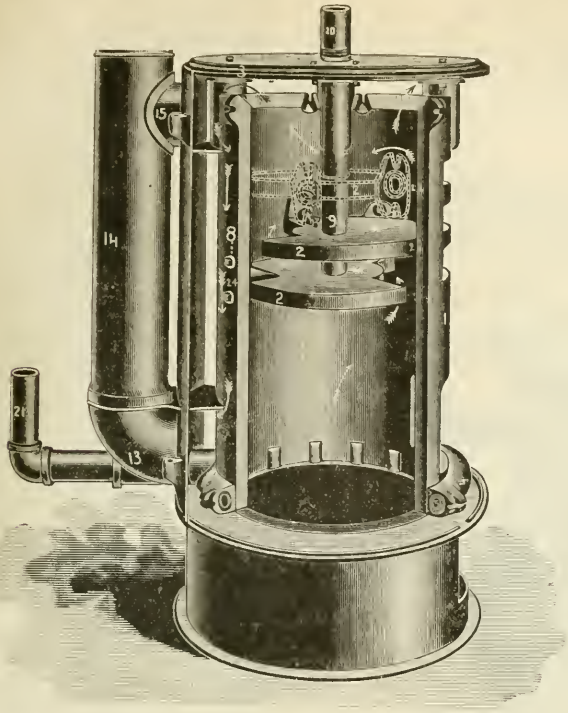
HEATING NOTES.

The erection of greenhouses and conservatories with their specially designed structural iron work adds largely to the demands on Hitchings & Co. of 233 Mercer street, New York, whose hot-water apparatus and system of heating horticultural buildings have been in use since 1844. Their hot-water boilers, however, are not confined to hothouses, many being used for heating residences and public buildings. In addition to their heating apparatus and structural iron work they make a complete line of hot-water fittings suited to their business. They have secured at the World's Fair a space of 60 x 75 feet on the grounds for a conservatory, and 20 x 25 feet in the buildings for exhibition purposes. At present they are completing for Geo. Pullman, at Pullman, Ill., a very large and handsome conservatory. The dome of the central section of the palm house will be 40 feet high, and all the rafters will be curved at the end, resting on the upright section, giving a very handsome effect. The house will form three sides of a square, and in one of the angles will be located the cottage of the florist. The entire conservatory and the cottage will be heated to the different temperatures required by their hot-water apparatus and system. One of their popular productions they call the amateur portable green house, which is 17 feet long and 9 feet 6 inches wide, and they make this so that it can be shipped complete, frame, glass, water heater, pipe and all, to be erected by local mechanics.

Sealed proposals will be received at the office of the custodian of the United States Custom House, Providence, R. I., until May 16, for the heating apparatus in the United States Custom House at Providence.

Lawrence Tivy has just moved to new quarters at 62 John street, New York, where he will continue to make a specialty of steam and hot water heating apparatus. He points with pride to the Germania Building, at William and Cedar streets, New York, which is heated by the indi-

rect system and proved a highly creditable piece of work under the severe weather of last winter. A reheating system in connection with a sugar manufacturing plant has recently been installed by him in Honolulu, Sandwich Islands.



Morgan Hot-Water Boiler.—Fig. 1.—Sectional View.

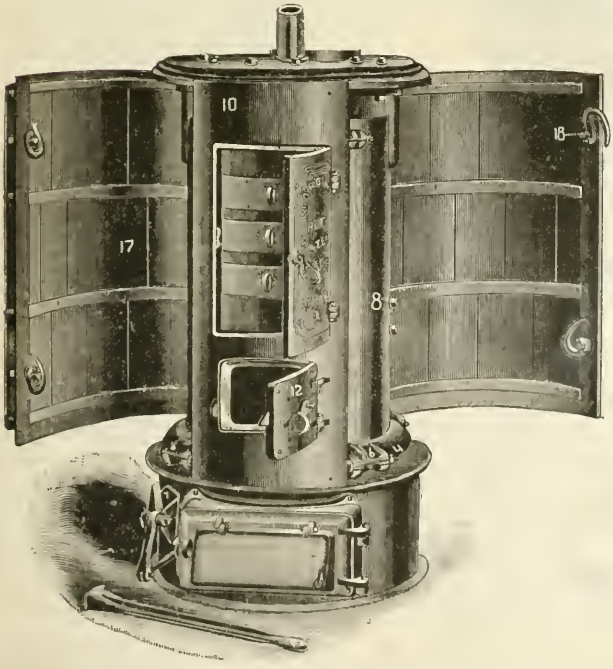


Fig. 2.—Morgan Heater with Swinging Jackets Open.

THE HANLON MFG. COMPANY, Pennington, N. J., distribute to the trade an illustrated and descriptive circular of the Hanlon automatic boiler feeder for low-pressure steam, which is the device that was illustrated some time ago in our columns. The present circular, containing some ten pages, is printed on a fine quality of paper. The illustrations show the boiler feed, also the valves connected with it, while the descriptive text gives a full account of the operation of the device. In the pamphlet there are also directions for placing the feeder, and a list of companies indorsing it is likewise presented.

SEALED PROPOSALS will be received at the office of the custodian of the United States Custom House, Detroit, Mich., until May 12, for labor and material required for repairs in the heating apparatus in the above named building.

THE GURNEY HOT-WATER HEATER COMPANY, 163 Franklin street, Boston, Mass., issue their annual trade catalogue relating to the various apparatus of their manufacture. The volume, with the general appearance of which the trade is familiar, is a square pamphlet, bound in red paper and with handsome gilt effect on the front cover. The printing is done in brown ink on a very fine quality of paper, showing the cuts and type to excellent advantage. In their introductory note addressed to the trade, they speak of the immense range of power secured by the Double Crown heater, and also refer to their Gurney No. 100 Series, as well as to the 300 Series. In the beginning of the catalogue is a careful account of the Gurney Double Crown heater, followed by general and broken views of the apparatus, together with illustrations of the separate parts. Then come lists of sizes and capacities. Cuts are presented showing the Double Crown set in brick for the purpose of indirect heating. Further on similar illustrations and descriptions are given of the 100 and 300 Series Gurney heaters, and the Defiance hot-water heater is noted. At the close of the pamphlet the Gurney hot-water radiators are illustrated, and tables of sizes, dimensions and prices presented. A specification for a hot-water heating apparatus is an interesting feature of the book, the specification, which defines all the work to be done, being accompanied by the floor plans of a house. An index and a number of useful tables complete the publication.

PIPER, DOREMUS & CO., 257 Greenwich street, New York, who import and manufacture bronze powder, metal leaf, brocade, gold paint and bronzing liquid make a specialty of radiator bronze and find a large demand for it in the steam and hot-water heating trade.

Morgan Hot-Water Boiler.

The accompanying illustrations show the new Morgan hot-water heater made by the D. F. Morgan Boiler Company of Akron, Ohio, and 85 Center street, New York. Features of the heater to which special attention is called are the quantity of water which the heater contains and the construction, which it is said effects a rapid heating and starts a circulation in the system at once. A free rapid upward passage is afforded for the water through the heater and a direct draft of but 9 feet, or a long indirect down draft passage of as much as 35 feet in some sizes, is provided for the smoke and gases. The sectional view, Fig. 1, shows the internal construction. The heater consists of a cylindrical water chamber composed of four upright independent sections, to which are connected three heat intercepting disks which do not form a complete circle, and are so arranged that their open spaces make an indirect passage for the gases. At the bottom of the back section the return enters and the water flows into each of the other sections at the bottom through a special waterway. This return waterway and those of the heat intercepting disks, all of which are short, are the only

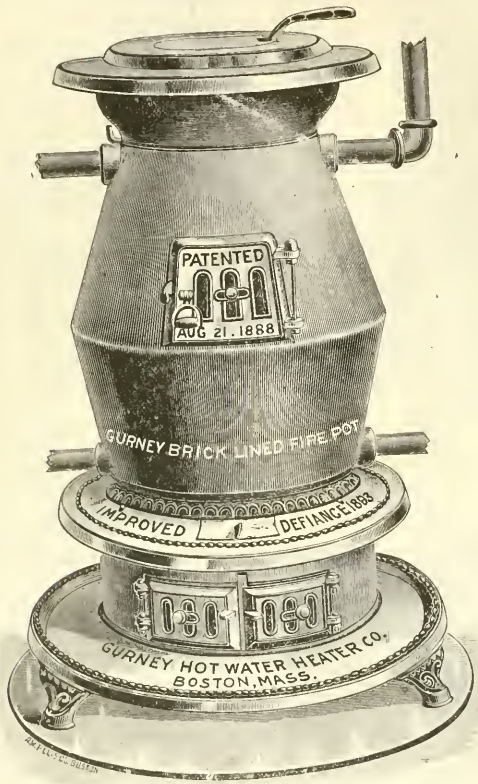
horizontal waterways of the heater, all the others being vertical facilitating circulation. The bottom disk connects with the back section directly over where the return enters, and having a pipe running direct from it to the dome immediately under the flow pipe, hot water is started through the system almost as soon as the fire is lighted. The two upper disks connect with the side sections and are so constructed that the water enters at one opening and passes all around the disk and back to the outer section through the other opening. An opening at the top of each outer section connects with the dome from which the flow pipe is taken. The outer shell or jacket is formed by a front and back section fastening securely to the base at the bottom and the dome at the top, the sides of the shell being formed by swinging jackets hinged to the back section. The front section has an ample feed door and a large door through which any accumulation can be removed. The back section has the smoke connections and to it are hinged two large swinging jackets which cover the greater portion of the circumference and are filled with a solid block of magnesia 1½ inches thick, forming an excellent non-conducting covering. The illustration, Fig. 2, shows the heater with these swinging jackets open exposing the interior. Between this outer non conducting shell and the water chamber the gases pass down when the direct damper is shut, their indirect passage being prolonged by baffle plates properly placed.

In the base which supports the upper parts is suspended a simple, labor-saving grate. The base also forms the ash pit which is provided with a door fitted air tight, which feature the manufacturers particularly emphasize.

The heater is made in five sizes, with grate surfaces from 1.5 to 6 square feet; fire pot 18⅝ to 36 inches in diameter, and a hight of 54 to 68 inches. The capacity of the boilers ranges from 400 to 2500 square feet of direct radiation.

Improved Defiance Hot-Water Heater.

The accompanying illustration shows the improved Defiance Hot-Water Heater, as manufactured this year by the Gurney Hot-Water Heater Company, 163 Franklin street, Boston. This heater is intended to meet the requirements of a first-class



Improved Defiance Hot-Water Heater.

heater; low in price. It is made in two sizes, No. 10 and No. 12. The No. 10 is said to be capable of heating 135 feet of radiation, and the No. 12, 200 square feet. This heater is furnished with the Gurney fire pot, with alternate brick sections. It is fitted with convenient shaking and dumping grate, has a 9-inch kettle hole on the top, and is provided with a combination deflector and check damper. It is specially adapted for use in small dwellings, offices, conservatories, stables, coach house, laundries, barber shops, bathrooms, restaurants and baptisteries, also for heating carving tables.

It is announced that O. Chan. Wells and Charles A. Coutan have retired from the management of the New York house of the Crosby Steam Gage & Valve Company, and have formed the Wells & Coutan Company, with offices at 29 and 31 Gold street, New York. The company will manufacture Standard Steam Vacuum and all other Gages and kindred goods, which department is added to their business. They have also been appointed sales agents of J. E. Lonergan & Co., manufacturers of Pop Safety, Water Relief and Snifter Valves, &c. William A. Locke, formerly salesman with the Ansonia Brass & Copper Company, has associated himself with the new concern.

The J. F. Pease Furnace Company, Syracuse, N. Y., have just issued from the press their 1893 (World's Fair Edition) catalogue of Economy low-pressure combination heaters, hot-water heaters and warm-air furnaces. The pamphlet is 7¼ x 10½ inches in size and is bound in tinted glazed paper covers, the design of the front cover being very tastefully executed. The interior of the pamphlet is in keeping with the decorations on the outside, for the cuts and letterpress are both excellent. Beginning with a general treatise on heating, followed by a short chapter on ventilation, the attention of the reader is directed to the Economy heaters and furnaces. Next comes an account of the Economy combination heater, a broken view of which is presented together with an accurate description, also table of sizes, &c. The Economy combination heater for steam and air, treated in a similar manner, follows, then the Economy combination heater for hot water and air. The Economy hot-water heater, which is next noted, is illustrated by a number of engravings, as is likewise the Economy all-steam heater. One full page illustration shows the Economy hot-water heaters in a triple battery as used in a school at Lowville, N. Y. The pamphlet then takes up the subject of warm-air furnaces, an introduction to the description of the several styles of furnaces being an account of methods of construction with reference to steel plate and its advantages. Small cuts also show the method of riveting the plates, while other illustrations show the form of fire pots. Six different furnaces are illustrated in this portion of the pamphlet, a couple of pages at the end being devoted to grates. A special feature of this publication is the testimonials which are interspersed between the different sections instead of being printed altogether at the end, many of the testimonials being accompanied by very pretty engravings of the residences heated. It is worthy of note that many of these testimonials were written after many years' experience with the heaters.

We are informed by Russell Wheeler & Son, Utica, N. Y., that owing to sickness in his family, which renders his presence at home necessary, C. S. Hopkins, who so satisfactorily represented the company in the West, has resigned his position, and the concern are now desirous of securing a competent man to fill the vacancy.

Ohio's building and loan associations, as shown by the report of the State Inspector, represent the savings of people in moderate circumstances, which exceed $74,000,000. This is over $11,000,000, or more than 17 per cent. greater than the aggregate capital of all the banks in the State, national, savings and private. In Philadelphia there are more than 400 of these institutions, and as good an authority as the *Public Ledger* says that "it is conservative to state that building society people here own at least a $2000 equity in 50,000 of the homes of Philadelphia."

The war vessels in the Naval Review in this port represented 117,720 tons, of which the new navy of the United States comprised 39,793 tons, or a little more than one-third. Great Britain alone had 19,320 tons, represented in four vessels—nearly one-half the tonnage being in the "Blake."

PLUMBING AND GAS FITTING.

How to Make a Wiped Joint.

The number of inquiries that are being continually received from our correspondents for information about joint wiping has prompted us to republish in pamphlet form two articles on the subject that appeared in *The Metal Worker*. The first of the two descriptions was published in *The Metal Worker* as a serial article April 4, 18 and 25, 1891. It was written by a practical plumber and was illustrated with half-tone engravings made direct from photographs of the work. The second article, illustrated by engravings made from photographs, showing the operation, was written by a prominent master plumber and was printed in *The Metal Worker* of June 11, 1892. These two articles give a very comprehensive account of the difficult work of joint wiping, and will, we believe, give as much information as it is practicable to put into print of this work, which requires so great a degree of manual dexterity. The pamphlet, which measures 5½ x 8 inches in size, will be furnished on receipt of 25 cents by addressing David Williams, publisher, 96–102 Reade street, New York City.

Laying House Drains Without Broken Joints.

From W. S., *Astoria, N. Y.*—You would help plumbers who have not much chance to learn the best way to do things if you would give in *The Metal Worker* an illustration of how to run a house drain in a cellar with a rocky bottom without breaking joints and by using Y branches and ⅛ bends. You printed something about it recently but I did not well understand it.

Answer.—In *The Metal Worker* of March 25 a question similar to the above was answered, but no illustrations were given. The main point of information sought for was how to get around an obstruction (such as a rock which could not be removed) when laying a house drain in a cellar without making what are known as "broken" joints. We pointed out that a house drain could be laid without "breaking" a single joint: 1. By the use of ⅛ bends and straight lengths of pipe. 2. By using ⅛ bends and Y branches. 3. By the use of ⅛ bends alone, either of which, according to circumstances, will accomplish the desired purpose. We present herewith, in Figs. 2, 3 and 4, illustrations of each of these methods, which should suffice for "W. S.," as they show how bends and branches may be used and the broken joints avoided. Figs. 5 and 6 show how to connect the soil pipe and house drain by means of a Y and ⅛ bend, and by the use of ⅛ bends alone. The rocky bottom of the cellar does not render the use of these fittings more imperative, but in the illustration an obstacle to the straight running of the drain is presented in the shape of a square slab forming the base of an iron pillar. To get around this it will be seen is very easy when one knows how. It will be easy also to judge, from the line of broken joints laid, Fig. 1, of all the obstacles presented to the free and unrestricted flow of sewage in a drain so laid, and the many chances for obstruction presented. We here repeat for our correspondent's benefit, that while ¼ bends are not allowed in good practice on horizontal draining, it is permissible to use two ⅛ bends instead of ¼ bend.

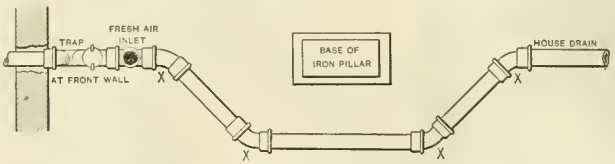

Fig. 2.—Drain Laid with Straight Pipe and One-eighth Bends.

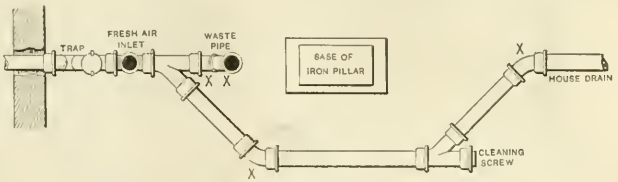

Fig. 3.—Drain Laid with Y Branches and One-eighth Bends.

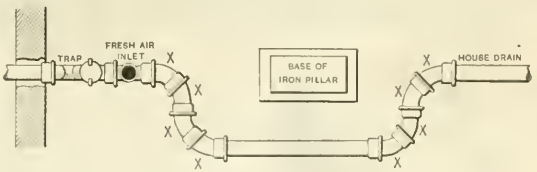

Fig. 4.—Drain Laid with One-eighth Bends.

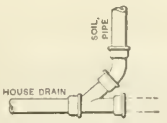

Fig. 5.—Soil Pipe and Drain Connected by Y and One-eighth Bend.

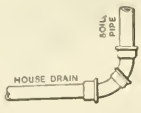

Fig. 6.—Soil Pipe and Drain Connected by One-eighth Bends.

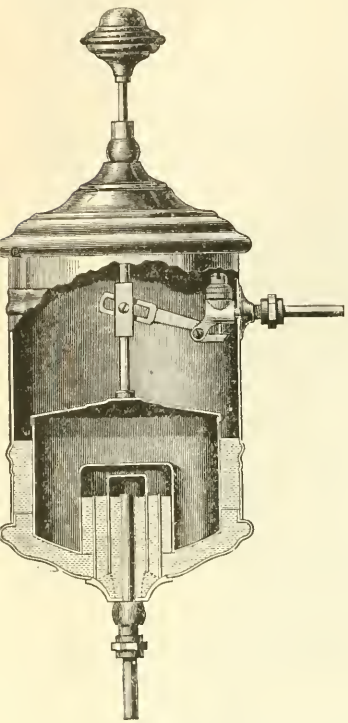
The Hydromaze.

James P. Hyde of 44 West 125th street, New York, is manufacturing an apparatus which he has patented and calls the Hydromaze, for automatically filling with water the traps of a plumbing system that may have become empty from any cause. A sectional view is shown in Fig. 1, and Fig. 2 shows the manner of connecting it with the fixtures already in use. In appearance it is a nickel plated cylinder about 6 inches in diameter and not over 12 inches in extreme hight, and it can be placed in the most convenient location. A ¼ inch lead pipe supplies it with water and a pipe of the same size

LAYING HOUSE DRAINS WITHOUT BROKEN JOINTS.

leads to the various traps connecting with them on their top side at the lowest point. Since branching the pipe does not interfere with its operation, one Hydromaze may be used in connection with several traps regardless of their different hights, as shown. The sectional view,



The Hydromaze.—Fig. 1.—Sectional View.

Fig. 1, shows the device at rest with all of the traps full. It consists of an outer cylinder, a central outlet pipe over which, with a space above and all around the fall of the float. The opening through which the piston passes at the top of the chamber is large and exposes the water in it to atmospheric pressure. In operation, should the trap empty from any cause, the pressure at the trap end of the ¼-inch pipe would be relieved and syphonic action started, which would fill the trap in a few seconds by emptying the Hydromaze, when the float would drop, opening the supply valve to refill the water chamber. The Hydromaze is made in different sizes, the largest being ample to meet the requirements of a large building.

A Noisy Range Boiler.

From W. N. N., *Washington, D. C.*—I notice in *The Metal Worker* of April 1 a description of a noisy range boiler by "F. H. & N.," Dundee, N. Y. If your correspondents will change their boiler connections, as shown in Fig. 1 of the sketches I

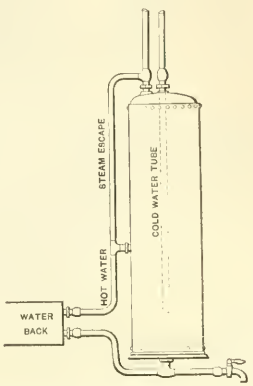


Fig. 1.—Remedy for Noisy Range Boiler.

send, I will guarantee that the boiler will be as gentle as a lamb. This connection was patented by John C. Ryan of Chicago about 1867, for a steam heating apparatus, and it is also a good arrangement for heating and small steam plants, it being steam heating this supplementary coil is not employed, the steam being taken direct from the top of the reservoir boiler. The

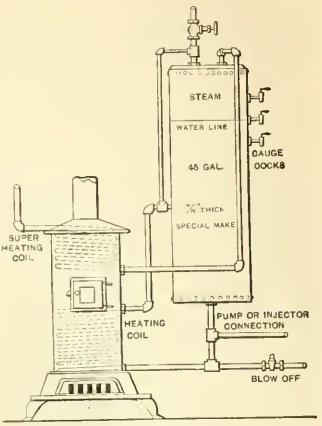

Fig. 2.—Ryan's Steam Apparatus.

lower coil contains 75 feet of 1-inch welded pipe.

TRAPS AND VENTS.

J. Toumey & Son, 132 East Forty-second street, New York, who make a specialty of wrought iron screw-joint pipe system of drainage, have work now in course of completion on a number of prominent buildings. They are placing about 400 plumbers' fixtures in the 11-story building of the Metropolitan Life Insurance Company at Twenty-third street and Madison avenue, and plumbing the office buildings at 10 to 16 East Twenty-third street, of which N. Le Brun & Son are the architects; the Lennox Library, Seventieth street and Fifth avenue, R. M. Hunt, architect; New York Society for the Prevention of Cruelty to Children building, Twenty-third street and Fourth avenue, Renwick, Aspinwall & Renwick, architects; Brokaw Bros.' new building, Eighth street, Astor and Lafayette place, Rose & Stone, architects; residence of E. W. Candee, Sixtieth street and Fifth avenue, John H. Duncan, architect.

As the result of the successful introduction of their goods into the New York market, through the persistent efforts of Manager John Pearce, Jr., the Wm. S. Cooper Brass Works of Philadelphia have set up a handsome line of samples at 43 Beekman street, which the trade is invited to inspect. A handsome enameled

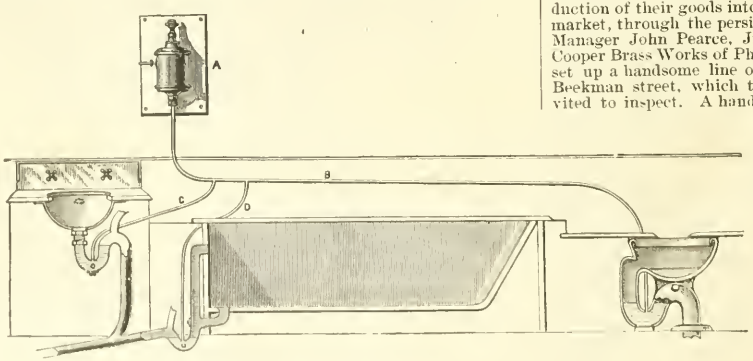

Fig. 2.—The Hydromaze Connected with Bathroom Fixtures.

pipe, is securely supported a cylinder closed at the top and a cylindrical air-tight float surrounding the inner cylinder with an intervening space. To the float is attached a piston, at the top of which is a chamber which may be weighted to balance the water pressure. Connected to the piston is a lever which opens and closes the supply valve with the rise and sufficient to run a six-horse power engine in a brass foundry. I am certain the patent has run out. The connection as originally applied is shown in Fig. 2. Where used for supplying steam to an engine the steam was taken from the top of the supplementary boiler and passed through a coil over the fire before being taken to the engine. If only used for bathtub fitted with their fixtures first greets the eye. Next comes the Nautilus water closet, which, it is claimed, possesses many superior advantages. The wood work being fastened directly to the closet, it sets out from the wall, so that it can be easily cleaned, leaving nothing to become foul. It requires no trap below the floor, and by its construction

permits a very material saving of time and material in setting. These closets are arranged along the wall, varying in finish from the plain to the beautifully decorated, and are ready to be tested by the purchaser. There are three handsome lavatories in pure white and Tennessee marble and onyx, set with handsome fixtures, finely plated. Together they make an exhibit well worth examination. The Hotel Savoy is fitted up with these closets and fixtures, and a recent order is for 26 of them in another fine building.

L. P. CLARK & SONS, Baltimore, Md., are issning a circular directing attention to what they call the original E. P. Clark's patent yard hydrant. Some of the merits claimed are its anti-wasting and anti-freezing features and the fact that it can be repaired without digging it out. It is made of cast iron and is sectional. By taking off the top and removing two brass screws the whole back section of the hydrant can be taken out, when all of the working parts can be removed for repairs or inspection with little trouble. It is pointed out that by a regulating screw the water supply can be increased or reduced and by the construction of the hydrant no water, it is said, wastes into the ground.

A SCARCITY of good journeymen plumbers seems to exist in Newark, N. J., according to the advertisements in the want columns in the daily papers, which is corroborated by the local houses.

IT IS SAID that numbers of high-priced buildings have lately been erected in St. Louis which have been wired for electricity, but no gas pipes have been put into them. Commenting npon this proceeding the *Progressive Age* says, in surprise: "We have known of builders in the West being guilty of erecting houses without gas pipes, believing gas to belong to the stage coach and canal boat age. But we have also seen the same builders or their successors tear down the handsomely frescoed ceilings and tear up the beautiful hard-wood floors of their buildings to place gas pipes, before they could get tenants to occupy their premises. We had thought, however, that that folly was entirely of the past."

SEALED proposals will be received at the office of the Supervising Architect, Washington, D. C., until May 17 for all the labor and materials required for the general excavation and temporary drainage, including sewer connection, of the U. S. Post Office building, Rome, Ga., in accordance with the drawings and specifications, copies of which may be had at the office of the Supervising Architect or at the office of the Superintendent at Rome, Ga.

A VERY PRETTY CIRCULAR issued by the Bailey-Farrell Mfg. Company, Pittsburgh, Pa., relates to the Globe hot-water heater of their manufacture. This device, for gas fuel, is designed for use with range boilers. It is illustrated and described in the circular and other interesting information concerning the heating of water is supplied. The circular is prettily printed in colored inks, and carries on the front page a picture of an angelic herald who is supposed to convey tidings to the trade of the Globe heater.

WILLIAM H. KAY has moved to 34 Dey street, New York, where he has better facilities for carrying and displaying a line of supplies for plumbers and steam and gas fitters.

THE CHICAGO BRANCH of the Smith & Anthony Stove Company, proprietors and manufacturers of the Sanitas Plumbing Specialties, have secured the adjoining store east, and will occupy the same in connection with their present sales room, thus securing a frontage of 40 feet on Lake street. The large basement will afford the necessary facilities for storage, &c.

Roof Area and House Sewer.

From P. J. G., *New Rochelle, N. Y.*—Will you please state if there is any rule among New York architects, or in force under the Building Department, which specifies any particular size of house sewer when taken in connection with roof surface? I have a one-story building for a summer pavilion in course of construction in which the fixtures are four water closets and other appliances. I made, as I considered, a correct estimate, calculating for a 5-inch sewer, but contracting to finish the work in accordance with New York sanitary practice, and when the work is almost finished the architect comes along and tells me I must put in a 6-inch sewer, such as they do in New York under similar circumstances. I have made inquiries and can obtain no information as to the regulation the architect speaks of, and before taking up the 5-inch sewer and replacing it with a 6-inch pipe would wish to know if such a rule is in existence.

Answer.—Under ordinary circumstances our correspondent would have supplied, in a 5-inch pipe, ample means of discharge of roof water, but we suppose the difficulty lay in the contract to finish the work in accordance with the rules prevailing in New York City. While the Health Department formerly, and the Building Department at present contents itself with providing pipes sufficiently large in caliber to discharge house wastes, the Department of Public Works has something to say in the matter of rain water discharge pipes. When the roof area of a building, no matter what may be the hight or the number of sanitary fixtures therein, equals 5000 square feet of surface, this department requires that the diameter of the house sewer must be not less than 6 inches. This rule is, we presume, to prevent the choking up of the sewer and the consequent flooding of cellars. Increased roof area above certain points calls for larger pipe. It is on the existence of this rule, evidently, the architect bases his objection to the use of the 5-inch pipe.

Laying Iron and Earthen Pipe.

From W. J., *Princeton, N. J.*—Can you help me out in devising some plan by which I can lay a line of house drain, say 80 feet long, without having sagged joints by the time I am out to the front wall? Also, how can I know, when the sewer outside the house is earthen or salt-glazed pipe and laid by a man who makes a living by laying sewers, that it is properly put down? My boss is sick, and for the first time the care of a very particular job of house plumbing is in my hands. Please enlighten me on these points in the columns of *The Metal Worker*.

Answer.—The best, or at least a very good plan, for our correspondent to adopt at the beginning is to determine what the grade of the house drain is to be. If the fall is to be ¼ inch to the foot he should provide himself with a straight-edged strip of wood 5 feet in length, and nail to the under side of one end of it a small block 1¼ inch in hight. This block represents the fall of ¼ inch per foot in 5 feet—that is, in each length of iron pipe. When adjusting the respective lengths preparatory to the calking of each joint, the strip should be laid from the hub of the last length of pipe calked to the hub of the length being put in position, the end with the block attached being toward the descent of the drain. Midway between the hubs a spirit level should then be laid on th strip, and if it indicated the necessity for lowering or raising the pipe this should be done until the exact level was obtained. By this means a uniform fall of 1¼ inches to each length of pipe would be secured, care being taken to properly support each joint during the process so as to avoid displacement before the calking takes place. As regards the earthen pipe the same rule holds good, only that a 2-foot strip with a ½-inch block would suffice—earthen pipe being generally in 2-foot lengths. Before connecting the house drain with the earthen sewer it is advisable to run a straight-edged strip of wood into the latter so as to detect any irregularity which might exist in the adjustment of the spigot end of any of the lengths of pipe, and avoid possibility of obstruction to the free outflow of house sewage. Care should also be taken, for the same reason, that when making the joints no cement should be allowed to remain inside the pipe.

Massachusetts Plumbers.

In *The Metal Worker* of April 29 we referred to the meeting called by Daniel G. Finnerty, vice-president of the National Association of Master Plumbers of the United States, to be held at the Builders' Exchange, Worcester, Mass., on May 1, for the organization of the State Association. The meeting was duly held and called to order by Mr. Finnerty, there being about 150 representative master plumbers present. The result of the meeting was the formation of a Massachusetts State Association, with the following officers:

President, William H. Mitchell, Boston; vice-president, John W. Jordan, Worcester; corresponding secretary, Daniel Shannon, Boston; financial secretary, C. P. Lyman, Holyoke; treasurer, F. W. Tower, Springfield; Executive Committee, the above officers and James F. Dadmun of Somerville, William N. McKenna of Boston, O. S. Kendall of Worcester, Mr. Kenally of Springfield and Mr. Kennedy of Holyoke.

The business session was followed by a banquet tendered by the local association to the delegates.

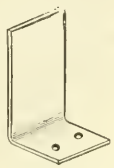
That cotton mills in the South pay when properly managed is again attested by the annual report of the Graniteville Mfg. Company of Augusta, Ga., just submitted to the stockholders. The earnings of the company for the year ended March 1 were $107,020.21. A 10 per cent. dividend, which is $60,000 on the capital stock, was paid and $42,000 were expended for new machinery and $6000 for other improvements. This is regarded as a wonderful showing for the Graniteville and Vancluse mills of the Graniteville Mfg. Company. Vancluse was built at an expense of $361,513.24 out of the profits of the Graniteville mill. The original capital was $600,000. The total surplus, March 1, 1893, is represented by $684,034.17.

West-bound freight rates from New York to San Francisco are reduced from 20 to 75 per cent. and over, embracing almost every commodity. This step is the beginning of the long threatened fight between the Southern Pacific Railroad and the new transcontinental freight line formed by the North American Navigation Company, the Panama Railroad and the Columbian Steamship line. The Southern Pacific people issued a new schedule of freight rates for west-bound business from New York to the California Terminals, which cuts under all figures previously quoted in the carrying traffic for the same distance.

ROOFING AND CORNICE.

Columbia Roofing.

A form of roof covering which has been introduced to the trade by the Columbia Roofing Company of Canton, Ohio, is made of the best quality of steel, thoroughly painted on both sides and put up in rolls 50 feet long by 26¾ inches wide. It is known as the self-capping roll roofing and is offered to the trade as something new in this line. The manufacturers state that every sheet is inspected before painting and the utmost care taken to see that all are free from holes, blisters and other defects. Each roll will lay one square of surface and can be used on any flat or pitched roof. The makers recommend it for flat-roofed buildings, as the edges are easily turned and a simple water-proof standing seam can be made. It is claimed to form its own ridge and hip caps by folding a seam which extends from end to end. The cleats are of simple construction, and, with the clinched eyelet fastening, it makes a substantial water-proof standing-seam roof. In Fig. 1 we show the general appearance of the cleat, while in Fig. 2 the cleat is represented fastened with a clinched eyelet to a 1¾-inch turned edge. The finished standing seam is represented in Fig. 3 of the cuts. The company have issued a little catalogue in which their specialties are described. Among these we notice pressed standing-seam roofing, made of what is described as semi-steel; also pressed steel brick siding, made of sheet steel and painted, while another form of siding is made of rock-faced brick. A square of this material consists of 8⅓ sheets, 60 inches long by 28 inches wide, painted on both sides and weighing 70 pounds. The company state that in ordering plain or rock-faced brick siding an allowance of from 4 to 6 square feet to the 100 should be made for laps.



Columbia Roofing.—Fig. 1.—General Appearance of Cleat.

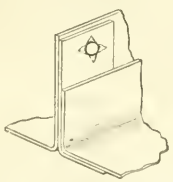


Fig. 2.—Cleat Fastened with Clinched Eyelet to 1¾-Inch Turned Edge.

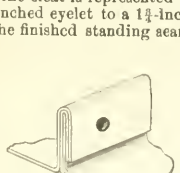

Fig. 3.—Finished Standing Seam.

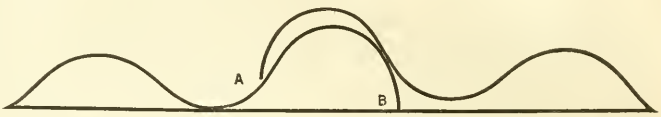
Patent Edge Corrugated Iron.

The Cincinnati Corrugating Company of Piqua, Ohio, are manufacturing what they designate as Patent Edge corrugated iron, illustrations of which are presented herewith. Among the special features to which attention is directed may be noted the economy of the laps and the water-tight joints which are secured by the style of corrugation employed. The company claim that the great defect heretofore in the use of corrugated iron for roofing purposes has been the leakage of the side laps, and they state that with their patent edge iron the whole roof may be flooded and yet the lap joints remain high and dry, thus giving both a wind and water proof roof. The outside corrugation of each sheet represented by A B of Fig. 1 is made with an improved edge which is ¼ inch deeper than those in the interior of the sheet. The manufacturers claim for the improvement that the nails used in fastening, being driven vertically through the tops of the highest corrugations, as shown in Fig. 2, it is impossible for the roof to leak, as the nail heads completely cover the holes and the water rapidly drains away. They also refer to the fact that the flange with this style of corrugation hooks tightly its entire length and that the edge flanges of the sheets being vertical rest on the roof supports, as at B, thus firmly upholding the lapped joint and keeping it water tight without the use of wooden strips. Reference is also made to the great saving in the amount of material required to cover a given space, as only one lap is necessary to form a perfectly tight joint. The illustrations which are presented herewith represent outline sketches of the ends of the sheets before and after nailing.



Patent Edge Corrugated Iron.—Fig. 1.—View of Edge of Sheets Before Nailing.

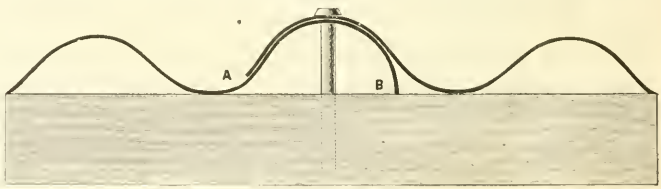


Fig. 2.—Appearance After Nailing.

Felt or Paper Under Tin.

From G. D., *Saugerties, N. Y.*—Is there any advantage in having felt or paper under the tin covering of a roof? I have heard it said that paper is liable to draw dampness which would cause the tin to rust on the under side.

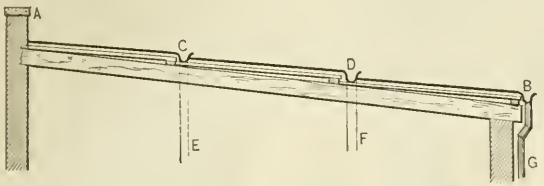
Note.—We would refer our correspondent to the letter from "W. C." of Jacksonville, Fla., in the issue of *The Metal Worker* of March 4, 1893. This communication will, we think, be a satisfactory answer to him on this subject. The use of felt or building paper is to be recommended under the tin on a roof and we may add that instead of drawing moisture it has directly the opposite effect.

The Berger Mfg. Company of Canton, Ohio, have just issued from the press an exceedingly attractive catalogue of 120 pages, which is intended to supersede all others. In size it measures 6 x 9 inches, is printed in a satisfactory manner and is bound in colored paper covers with embossed lettering in green upon a terra cotta ground. The company state that since their sixth annual catalogue was issued they have added to their factory the latest improved machinery, giving exceptional facilities for the production of sheet metal goods. In the publication before us, attention is directed to a wide range of specialties, including Berger's Patent Simplified Steel Roofing, Berger's Pressed Brick Ceiling, window caps, cornices, crestings, eave trough, elbows, finials, hangers, conductor pipes of various kinds, ridging and other goods likely to interest those engaged in the roofing business or having to do with building construction. The illustrations are numerous, showing the general appearance of many of the goods turned out, as well as their application. A number of pages in the book are devoted to illustrations of buildings in connection with which the company have used their goods. The catalogue, considered as a whole, gives evidence of careful arrangement and attention to details and

is likely to prove of interest and value to all those in the trade into whose hands copies may come.

Parallel Troughs on Roofs.

From J. B. M., *Saquache, Col.*—In the case of large buildings that are covered with a standing-seam tin roof, the water course is too long. As enormous quantities of water rush to the lower part of the roof, the standing seams are covered and some of the water is liable to find its way into the building. Would it not be a good plan in such cases to put a number of troughs across the roof, each of the troughs being provided with a down spout at the side of the building? In the accompanying diagram let A B represent the side view of a long roof. The usual trough would be placed at B, and the down spout at G. By having parallel troughs at C and D, and down spouts at E and F, the great rush of water at B would be avoided, troughs C and D each taking their share, which



Parallel Troughs in Roofs.—Plan Suggested by "J. B. M."

would be conveyed away by means of the down spouts E and F. Will the readers of *The Metal Worker* give their ideas regarding the value of the scheme?

Output of Slate in 1892.

The vast quantities of slate which are used every year for roofing purposes, and in connection with building construction generally, renders very interesting statistics bearing upon the subject. Many of our readers are, therefore, likely to find profitable study in the following figures, which are given in a recent issue of the *American Slate Trade Journal*, as showing the production of slate during the year 1892:

Regions.	Number of Quarries.	Production of roofing slate in squares.	Total value of roofing slate.	Total value of other manufactured slate.	Total value of entire product.
Bangor region, including the Pen Argyl and Hard Vein sections	60	360,000	$1,080,000	$200,000	$1,280,000
Lehigh region, including the Walnutport and Danielsville sections	47	155,000	555,000	225,000	775,000
Vermont and New York region, comprising Rutland County, Vt., and Washington County, N. Y.	77	310,000	900,000	300,000	1,200,000
Peach Bottom region	10	28,000	138,000	4,000	142,000
Maine	5	46,000	234,000	6,000	240,000
Virginia	4	24,400	93,600	2,400	9,000
Totals	203	924,000	$2,995,600	$737,400	$3,631,000

The year just closed has been one of satisfaction and profit to the slate operators in general. In the Vermont and New York region the output of sea green slate has been large and trade exceedingly good, much better even than during the previous year, when the quarries were operated to their utmost capacity and the entire product readily marketed. The shipments of this slate are principally to the West, and it is used where its cheaper price atones for its poor color. The shipments by the Vermont Slate Company, which controls the sea green product, were 225,000 squares, and show a material increase over 1891. The company enters the sixth year of its existence under very propitious conditions, all knotty points coming before the annual meeting in December having been thoroughly and amicably discussed and remedied in a business-like manner. No changes were made in the prices, the old schedule remaining in force until April 1, 1893. The unfading green and purple maintained their position and price as fancy slate. The red still command their high price, but even at that figure, on account of the smallness of the beds and difficulty in quarrying, are scarce. The manufactured slate dealers in the Vermont region have been somewhat hampered by competition and lack of organization, and in consequence have not operated their plants to their full capacity. The black Maine slate still ranks among the fancy articles and commands prices accordingly. It is finding some sale in the West, but is principally used in the New England States.

In Pennsylvania all branches of the trade report prosperous times, except school slate manufacturers, among whom business is a little dull and prices rather low. In the Bangor region all quarries turned out an increased product during 1892, yet have fewer slate on the bank than for years past. In Pen Argyl there is a very light stock on hand, and thorough and harmonious organization would command good prices for the spring trade. In the Lehigh region the outlook is good and prices fairly firm. The manufactured slate dealers in the Bangor and Lehigh regions have had a good year, and the prospects for a lively spring trade are exceedingly flattering. In the Peach Bottom and Virginia regions the year just closed has been satisfactory and profitable, and the manufacturers express confidence in the present season. The reports from the West are unusually good for this season of the year, showing a demand on many sizes exceeding the supply. The business is steadily extending to new districts, thus increasing the demand and keeping trade healthy. There is, however, still ample room for new markets, and it is confidently expected that the present season will witness the introduction of slate in many new localities and a corresponding increase in the output and sales.

FLASHINGS.

A RECENT ISSUE of the Decatur, Ohio, *Daily Republican* contains a flattering notice of the Decatur Steel Roofing & Corrugating Company's plant, the manager of which is L. S. Benbrake. In anticipation of a largely increased trade for this year the firm have made changes and improvements all through their plant and are now in a position to avoid all delay in shipment of goods. They have also laid in a large stock of material, so that there will be no trouble from a scarcity of supplies.

THE CORTRIGHT METAL ROOFING COMPANY, Philadelphia, Pa., are now prepared to furnish a new size, 7 x 10 inches, of their Victoria metal shingles. Heretofore they only made one size, 10 x 14 inches, but this proved so popular that the company have added a smaller size, which they particularly recommend for ornamental bands, gable ends, towers, &c. The shingle has the same side lock and top and bottom overlap as the other goods which they make and which have met with such success.

THE NEW ENGLAND STEEL ROOFING COMPANY, with headquarters at Worcester, Mass., are making an improved form of roofing adapted for use in connection with all kinds of buildings and in all climates. The construction is said to be such that it can either be laid on sheeting boards or lath, and without the use of outside cleats which are likely to become loose, hold dirt and dampness and cause corrosion. The roofing is known commercially as the New Improved H. W. Smith Patent Folded-Lock Standing-Seam Steel Roofing. The company are also prepared to furnish all styles of sheet-metal siding, roofing, slip-joint eave trough, conductor pipe, hangers, ventilators, crestings, finials, &c.

THE LUDOWICI ROOFING TILE COMPANY, which is composed of such well-known Chicago men as George Schneider, Henry W. King, Cyrus H. McCormick, and Carl Ludowici, have begun the construction of their plant at Chicago Heights, which will cover 10 acres of ground and give employment to a huge army of men. In selecting a location for the establishment of this large plant in America Carl Ludowici of Germany visited this country, and, in company with his American associates, made a careful investigation respecting the proper point at which to locate an industry of this magnitude.

THE PRENTICE PATENT METALLIC HIP SHINGLE is meeting with no little favor at the hands of the trade, and we understand from the manufacturers, the Metallic Hip Shingle Company of Toledo, Ohio, that it is indorsed and recommended by architects and sold by the hardware trade and builders' supply dealers. It is referred to as being of such construction as to completely protect while ornamenting a hip, making it absolutely water tight and firmly holding the shingles without exposure of nails. The company also refer to the economy of labor, time and materials in the use of this hip shingle, and state that cuttings from valley shingles may be used on the hips, enabling a carpenter to lay three times as many shingles in a day as would otherwise be the case. The hip shingle takes the place of unsightly and cumbersome saddle boards and hip rolls, and leaves a clean-cut line up the hip. The company state that they furnished 10,000 last season for the Grand Victory Hotel, located at Put-in-Bay Island, Ohio.

GEORGE L. FISK, Ellisville, Ill., is the patentee of an eave trough attachment, which consists in providing the opening leading from the trough to the drain pipe with a suitable attachment to prevent leaves and other accumulations from entering the pipe. The first claim covers a pivoted trap located in the trough, so arranged that it is easy to discharge accumulations and reset it.

WORLD'S FAIR NOTES.

The Fine Arts Building.

There are two annexes to the main art galleries. These are called the east and west pavilions, says the Chicago *Herald*, and their connection with the central pavilion is by means of corridors, which are also used as galleries. The east pavilion contains the French Government exhibit, and also the French masterpieces owned by Americans. The west pavilion contains the Italian exhibit and the exhibits of several other foreign countries whose space is limited. The central pavilion has two floors for the exhibit of paintings. The northeast section, or one-fourth of the space for paintings, is devoted to the works of United States artists. The southeast section is given up to Great Britain and Canada. The southwest section contains the works of art sent by Holland, Spain, Russia and Japan. The northwest section contains all the German paintings. In general terms, the oil paintings are all hung on the ground floor in the central pavilion, while water colors are on the second floor. There is an overflow exhibit of oil paintings upstairs in the American section.

Between these four quadrangles are four courts and the central rotunda. The north and south courts will contain the groupings of statuary. The east and west courts will contain the archtectural exhibit. Here will be seen structures and casts illustrating ancient, mediæval and modern architecture. There will be cases of antique and modern carvings, and architectural drawings will be hung on the walls.

The central rotunda will contain a heroic figure of Washington by Thomas Ball. On the sides of the rotunda are 12 spaces for figure groupings furnished by different foreign countries. There are also rotundas in each of the smaller pavilions, where statuary and architectural specimens will be grouped. There are 80 galleries in all, including the east and west pavilions. These range from 30 feet square to 36 x 120 feet for the exhibition of paintings. There are also 108 alcoves, fronting on the court of the central pavilion. Twenty-eight of these are on the first floor and 80 on the second floor, and much additional wall space is gained by their use. Engravings, etchings and black-and-whites are mainly up-stairs with the water colors, and pastels are down-stairs with the oils.

It is almost needless to say that the lighting arrangements are as faultless as can be devised. All the pavilions, including rotundas, courts and galleries, are lighted from above. The modulation of natural light in the daytime is simple and effective. The system of artificial lighting at night will be a work of art. Myriads of incandescent lamps will shed a mellow radiance over courts and galleries. The electric lamps are arranged in clusters above each court, and also in continuous rows around the galleries. The attractiveness of the art galleries at night will be one of the features of the exposition.

So much praise has already been bestowed on the exterior architecture of the Fine Arts Galleries that little need be said on that score. Those who have seen the finished structure are enthusiastic over Mr. Atwood's magnificent design, and even the lay public pronounces it the architectural gem of the exposition. Whether seen for the first time across the lagoon from the south or from the main approach to the north, the splendid proportions of the classic pile lend dignity and charm to the varied surroundings.

The main building is the Grecian-Ionic architecture of the most refined type. The order is taken from the Erechtheum of the Acropolis at Athens. The east and west pavilions are of harmonious proportions. The entire structure is practically fire proof. The main walls are of brick covered with staff, and the roof is of iron, steel and glass. The circular stairways in the central pavilion are of iron. The aggregate length of all the pavilions is 1152 feet and their aggregate depth 504 feet.

The main approaches to the art galleries are imposing in design, and will be arranged in harmony with the general effect of richness and classic simplicity. To the north, and facing the State buildings, there is a Grecian court. A broad flight of steps leads up to the portico and colonnade. In the court are broad grass plats, which will have simple elevations of palms in unique vases. Near the outer extremity of the court there is to be a pedestal statue of Augustus Cæsar. On each side there will be a Roman exedra, or semi-circular stone bench. At each end of the court the classic decorations will be in the form of copies of the choragic monument of Lysicrates from Athenian ruins. Fountains and garden seats will combine estheticism and public comfort.

To the south the main approach to the art galleries faces directly on the north lagoon. A broad flight of steps leads down from the portico to the surrounding driveway. From the latter another still broader flight of steps leads down to the water landing, where the electric launches will take passengers for other parts of the grounds and deposit visitors to the art galleries. This is the most northerly water landing on the grounds.

It has been often said that the World's Fair architecture is destined to create a new era in the design of modern buildings. Scattered around are lessons in the composite, the mediæval, the renaissance and all the schools. Here in the art galleries the classic model is pure and superbly designed in keeping with its purpose. The interior exhibit, moreover, contains the greatest collection of architectural specimens ever brought together. The growth of the art from ancient and mediæval times to the present, and the various applications of sculpture to architechtural forms are here illustrated. Thus the outer and interior exhibits of this department of fine arts will in themselves constitute one of the crowning glories of the exposition.

Permanent Beauty of Jackson Park.

The landscape art of the exposition is one of the best things it has to show, and fortunately the best of it can be kept as the leading features of a splendid pleasure ground that will comfort thousands when the World's Fair is history. Its chief glories are the lagoon and islands and these can and should be preserved intact. The group of islands consists of the Wooded Island, Hunters' Island and a number of attendant isles and islets, some of them only large enough to give foothold to graceful semi-aquatic plants.

The treatment of the entire group is so artistic that one thinks only of nature—a result that should give satisfaction to the most exacting landscape artist alive. Plantations of such trees as make a rapid growth have been added to a grove of indigenous oaks. Outside of these the islands are fringed with shrubbery and great stretches of wild flowers growing in colonies as they do on the prairies and borders of woodlands, and in marshes all through Northern Illinois. Semi-aquatic plants troop down to the brink; tall reeds and other water plants rise from the lagoon itself, and on it its quiet surface lily leaves float dreamily, while the low outlying isles are tinged a living green by the sedgy things that creep to the water's edge.

Few realize the vast amount of work that has been done by the Landscape Department to bring about this and other delightful results. The planting alone, which is merely putting on the trimming after the dress is made, has been an enormous work. A work, too, that had to be done in a limited time and with a sure hand. There was no time to try again. The first trial meant success or failure, luxuriance or barrenness. No one who saw the islands last fall, when they stood painted to the rim with splendid masses of foliage and glowing groups of wild flowers, failed to appreciate the remarkable success of it all, although few knew what it stood for in detail.

There have been planted on the islands and in other parts of the grounds 12,618 trees, 50,644 shrubs, 151,394 hardy perennial, herbaceous and miscellaneous plants, 136,678 aquatic and semi-aquatic plants, 3300 ferns, 9582 vines, climbers and ornamental grasses, 60,000 willow cuttings, 114,920 bulbs and similar plants, and a great collection of native plants, which were used by the carload. Most of the latter are such as grow in the swamps, lanes and woodlands of Michigan, Minnesota, Illinois and Ohio, but several other States are represented. The trees used were principally willows, poplars, water maples, cherries, elms and lindens. The shrubbery consists of various kinds of low-growing willows, cornues, spiræas, loniceras, lilacs, snowballs and berries. These form the basis of the groups, but to give variety and test their adaptability to the climate many rare shrubs were added. The splendid success of this part of the work is modestly attributed by the superintendent of Messrs. Olmstead & Co. to the weather. The dry fall of 1891, followed by a mild winter and wet open spring, certainly was a propitious series of seasons for the work in hand, but that does not dim the fact that efficient head and hand work—all done under pressure—has been accomplished.

The inner, higher part of the wooded island, reserved for the use of the Floricultural Department, was laid out in lawns, flower beds, and a rose garden, while the extreme north end space was set apart for the Japanese Temple and garden, which are to remain as a permanent reminder of the patience, ingenuity, gentleness, good will, and love of beauty of the nation of artists. The flower exhibits on the island will form a long and charming procession. The wooded island is about 16 acres in extent, ten of which are devoted to the plantations of trees, shrubs, and native plants already described. Through the middle is the long sweep of lawns and flower garden, about six acres in all. At the south end of this space will be shown for the first time, it is believed, in the West a combination of plants and style of grouping that is seen on large places in the East, notably on the grounds of the Newport home of the late Miss Catharine Wolf, consisting of well-placed azaleas and rhododendrons; and in the partial shade of these shrubs great clumps of lilies in many varieties will be planted. The bulbs and shrubs bloom at different seasons, and thus the arrangement affords double pleasure.

Over the lawns north from this fine exhibit will be seen a green and flowery wall, the first hint of the rose garden—the glory of the island. This is a plot of 1¼ acres, oblong in shape, and will be inclosed by a wire fence supported by posts 9 feet high set at intervals of 8 feet. Between the posts the wire netting droops in curves, the lowest point of each curve being 6 feet above the ground. The fence will be lined with climbing roses, and draped on the outside with many kinds of light-growing creepers. This gracefully shaped, vine covered, flower-starred wall will be in itself a thing of beauty. Access to the interior will be at four points only, in the middle of each side and at the middle of each end, so the garden will possess the first requisite of a garden—seclusion. It will also possess the second—flowers. The

plot is divided into 36 beds of various sizes and shapes. Between the beds broad graveled walks wind their way to a pretty little pavilion in the center also smothered in vines. Surrounding the entire garden runs an irregular border, bounded on the outside by the green wall and on the inside by a continuous promenade. Fifty thousand roses are to be grown in the garden. Thirty thousand of them belong to the taller-growing, hardy class, and will be found in the beds. Twenty thousand tea and other tender roses of the low-growing kinds will fill the border, where they can be seen to the best advantage and have the grateful shelter from the wind of the growing wall.

The rose garden will be a revelation. On moonlit nights people will wait there to hear the nightingales that sung around the rose bower that blossomed by Bendemeer's stream. North of the garden will be found a great nursery exhibit, where the foremost growers of nursery stock will show ornamental trees and shrubs, such as home makers should know and use. Here will be specimens of everything of that class desirable for the decorative planting of either large or small places. West of the nursery exhibit a number of florists will have a great show of hardy herbaceous plants, one firm alone sending 10,000 plants. Still west of these England will justify herself for clinging to fine old herbaceous perennials, such as peonies, phloxes, &c., a class of plants grown to perfection by the English. Just south of the approaches to the Japanese garden Germany will display her formal favorites, such as stocks, asters, zinnias and dahlias. Thus the whole sweep of the lawns from end to end is utilized by the best-known plantsmen of Europe and America for their large and attractive exhibits.

The islands will be a great object lesson in beautiful landscape effects, while the interior of the largest one will show a series of object lessons as to what and how to plant, although not just where to plant it, as the space is too limited to admit of the best grouping.

The Midway Plaisance.

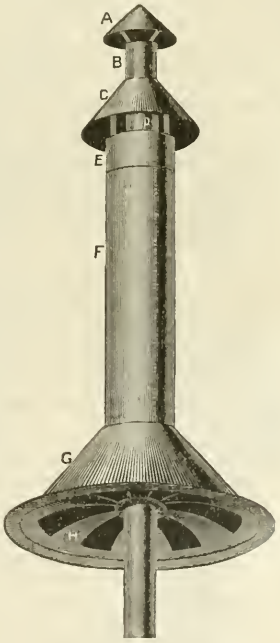
Those who visit the exposition to be entertained and amused as well as instructed will be greatly interested in the peculiar features of the Plaisance. This is a long strip of ground running at a right angle from the west boundary of Jackson Park. It is entered by a broad passageway near the Woman's Building. A macadamized street, formerly the Boulevard, from Jackson to Washington Park, extends through the center of this strip of ground, fronting on which are all sorts of structures built by persons who secured concessions for that purpose. An admission fee is charged for entrance to each of these attractions. The Plaisance is cosmopolitan. There is a "Street in Cairo," on which are quaint Egyptian buildings, peopled by shrewd merchants with their families. An Irish village is to be seen, as well as a reproduction of German home life. A Javanese settlement is shown, with its quaint huts and their thatched roofs and broad porches. The Turks have their mosque, Moors and Algerians have erected special pavilions and even the natives of Samoa are represented in this motley gathering. A famous German wild beast tamer has erected a large arena in which he exhibits his skill and prowess. Towering above everything is the huge Ferris wheel, about half completed, but covered with a swarm of busy workmen.

Tardy Exhibitors Will Suffer.

There are exhibitors who will not be ready on May 1, the same kind of men as a rule as those who are forever trying to take a 7.32 train at 7.34. They will find that it will be more expensive and difficult to get exhibits in place after the opening than it has been. The rule in regard to bringing exhibits on the grounds after the fair has been opened is that the goods must be delivered to one of the two warehouses belonging to the exposition, one of which is located at Sixty-seventh street and the other at Midway Plaisance. From there they will be taken into the grounds by the exposition teams during the night. This force of trucks will do its work in the night after the fair opens and the visitors will not see any belated exhibits arriving and will not see any of them put in place, for this work must be done during the hours that the gates are closed.

Jackson's Flue and Ventilator.

A combination flue and register designed for use in connection with buildings of all kinds, and more especially for ventilating the kitchens of dwellings, has been brought out by M. H. Jackson of 411 West Sycamore street, Kokomo, Ind. The construction of the device is claimed to be such that the flue takes from the kitchen all smoke, dust, steam and noxious vapors arising from the cook stove while in use. It keeps the house free from condensed steam and the effects of damp weather, while in summer it tends to maintain a circulation of air, rendering the kitchen more cool and comfortable than would



Jackson's Combined Flue and Ventilator.

otherwise be the case. The manufacturer states that the device is both a chimney and a ventilator, and that no chimney or flue is needed where it is employed. A general view of the device is shown in the accompanying illustration. Referring to the cut, H represents the cast register and G the flaring end of the ventilating stack F. At E is a sleeve which is designed to cover the stack. D is the central or smoke pipe. The cast register is fastened to the under side of the device by means of screws. The smoke pipe and ventilating pipe rest in castings as indicated in the cut. The device is made in three sizes, the No. 1 having a 32-inch cast register, 14-inch stack and either 6 or 7 inch smoke pipe, according to requirements. No. 2 ventilator has a 16-inch cast register with 12-inch stack, while No. 3 has a 10-inch register and a 10-inch stack, the central pipe in the latter cases being 6 inches in diameter.

Athol Spraying Force Pump.

The Athol Pump Company, Athol, Mass., have brought out an improved form of force spraying pump, an illustration of which is shown herewith. The pump is

Athol Spraying Force Pump.

made of brass, and is described as simple in construction, strong and durable and adapted to many uses. Besides spraying fruit trees it is used for washing windows, wetting lawns, testing pipes, pumping hot water for thawing out pipes, filling steam boilers, &c. It can be run by wind, steam or water power. We understand that they have been put in use where they had to pump against a pressure of 90 pounds of steam.

Robert T. Frazier has been appointed manager of the Washington office of Howson & Howson of New York, which has now been moved to the National Union Building, 918 F street. Mr. Frazier is a graduate of the Naval Academy at Annapolis, and has had an experience of five years as examiner in the Patent Office, having, at the time he resigned from the bureau to take charge of the Washington office, earned his promotion to the position of a principal examiner.

The onerous nature of the assessments to which strikers in labor organizations are compelled to submit is illustrated in a case cited by Eugene Debs, president of the new Western American Railway Union, who states that the Burlington strike cost the firemen $500,000 and a loss of 7000 in membership.

It is said in San Francisco that the Pacific Mail Steamship Company will soon make an Eastern connection via the Isthmus of Tehuantepec.

THE RETAIL STORE.

How to Keep the Store Neat and Clean.

SECOND ARTICLE.

By F. F. Gilmore.

The chief requisite is that the proprietor should be a man of judgment, clear ideas, and withal of a kindly nature. This latter characteristic will impart a feeling of ambition to the clerks to keep things in shape out of respect to the head of the house. A clerk is necessarily somewhat of a machine, but if he feels that consideration is shown him, he will unconsciously grow to the idea that his employer's interests are his own, and in this way be willing and anxious to use all means of preventing confusion in the stock and accumulations of litter about the floor. The stocks will be put back carefully, each piece of display goods will be kept arranged properly and the shelves show a neat appearance.

Of course, as first set forth, the merchant or his manager will have to embody the principles of neatness. Some men are born so, others achieve it by hard lessons, other storekeepers buy it, and have to pay dearly for the luxury.

MANY ORDERS ARE LOST.

The impression made upon a purchaser when entering a store by a trashy floor, unkept and mislaid stock, is anything but prepossessing, and many orders are lost by permitting the front part of the house, in both jobbing and retail business, to be used for packing and unpacking goods. It is very well to show in this way what a busy set of clerks one has, or what a big volume of business is being done, but many buyers hesitate to enter such a pandemonium. It is well to show the busyness of the clerks, but let them carry to a rear room the goods to be packed, and bring from there the new goods, bright and clean, to be neatly placed on the shelf or stowed in bins and cellar.

Every store should have a large, rough mat at the door to prevent bringing into the house mud, dust, &c. The doors to the different stock or display rooms should be kept shut. Change of temperature, or rather, the varying of wet and dry atmosphere, badly affects fine goods, and then, when one department is swept and dusted, the settlement should not accumulate on the other stock. And in the matter of sweeping and dusting, great art can be displayed, and no wise clerk or good porter should object to being thought effeminate in the discharge of this part of the work. Clerks should take pride in keeping their stocks clean and attractive, and notice of credit as well as fault-finding, should be shown by the proprietor.

THE MOST CONVENIENT PLACE.

Wherever sprinkling can be done on the floors it is probably the quickest means of allaying and preventing dust in cleaning up, but wet sawdust is nearly as handy and much better adapted to a Hardware house, as the floor is not wet much and not so much evaporation is given off. Out on the street or pavement is the most convenient place to deposit the sweepings of dirt, litter, scraps of paper, &c., but the fire place or ash barrel is a far more decent place to get rid of them.

Where it is possible it will be found very serviceable to have curtains of light material to hang in front of shelving from the ceiling while the sweeping is going on, and to hang these from Saturday evening until Monday morning. And as the force of clerks should be in reality a trained body of men or boys, they could easily put away the curtains in short time and dust their stock over, and at night, cover them up again; and as each stock should be looked after by a certain clerk, it will not be a hard matter for him to put away and collect his goods that were scattered by other salesmen showing customers around.

THE MOST ATTRACTIVE FEATURE.

It should be a rule, too, for the clerks or salesmen who go around with the buyers, and necessarily take down and handle many sensitive goods, to go back and put away those articles; and the proprietors and their "bossy" sons, should be willing to show this amount of consideration themselves.

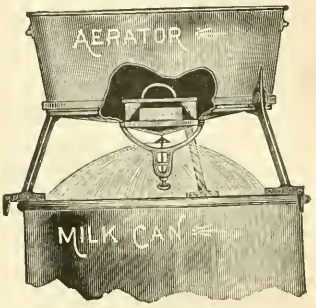
The show windows of a large house should be the most attractive feature of the building, and under the constant care of a man who thoroughly understands art in exhibiting goods. The displays should be constantly changed to represent the needs of the various seasons and changes of weather. The windows should be kept scrupulously clean, and have glass between the display goods and interior of store. It will pay to burn a gas jet day and night in these, turned down and out of sight, to prevent the condensing of moisture on the glass and goods.

Although it may be a good idea to receive and ship many goods through the front part of the house, to keep before the public and visitors the thrift and volume of business done, yet in most cases it is best to let the goods go out of a side or rear door.

Let the proprietors be polite and considerate to the clerks, appreciating neatness and original ideas, giving some leaway to the developments of the future merchants and yet demanding or rather requiring promptess and dispatch, and there will be found very few young men who would not consider it an honor to be connected with such a firm.

Baird's Cooler and Aerator.

A. M. Coon, Leonardsville, N. Y., is introducing the above article, as illustrated herewith. In operation the pressure of milk falling on a small wheel with reaction buckets causes the wheel to revolve, while a set screw under the wheel allows the pressure to be increased or diminished, causing the wheel to run fast or slow, according to the number of milkers. The point is made that this arrangement dispenses with the necessity of perforations in the bottom, and that all the parts being detachable and thoroughly tinned renders it easily cleaned. The manufacturer claims that the device thoroughly removes all animal heat and gases from the milk and reduces to a minimum the labor of properly caring for it, as it is considered by experts that thorough aeration of the milk is necessary to obtain the best product of butter and cheese.



Baird's Cooler and Aerator.

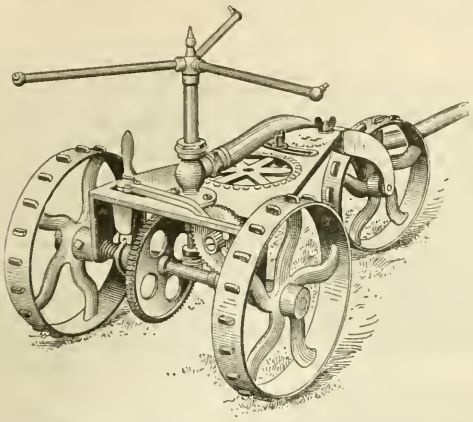
Thompson's Sample Holder.

The illustration herewith given represents a Sample Holder put on the market by Massey & Thompson, Monroe City, Mo. The holder consists of a steel plate to which an oil-tempered spring is fastened, the plate being held on the shelf by means of two round-headed screws. They are made in three sizes to hold any article to be displayed. It is remarked that among the conveniences resulting from this device is that the sample can be sold each time and a fresh one put in its place without loss of time or trouble; also that it will prevent the accumulation of shopworn samples, and will save much time and annoyance in avoiding the necessity of wiring on samples. Samples will be sent by the manufacturers upon the receipt of 5 cents in stamps.

Thompson's Sample Holder.

Little Giant Traveling Lawn Sprinkler.

The accompanying cut represents a sprinkler put on the market by the Portland Lawn Sprinkler Company, 98 Exchange street, Portland, Maine, and 32 Oliver street, Boston, Mass. Its construction is such that it has the capacity of moving itself over the lawn, or may be used stationary at any point desired. The manufacturers state that under an ordinary pressure of water it will roll itself slowly and steadily in any direction, either in a straight line or in a circle of any diameter desired; that it can be set to travel anywhere from 15 to 500 feet an hour, as preferred, and can be changed from the lowest to the highest speed in a moment; that it can be gauged to throw the water over a swath anywhere from 5 to 50 feet in width, or can be used as a stationary sprinkler by throwing it out of gear; that it has a figured dial by which it can be adjusted to travel any number of feet, and that it will stop automatically after covering the desired distance. It is claimed that with a pressure of water as low as 20 pounds it will drag 75 feet of hose, while with a pressure of 60 or 70 pounds it will carry 200 pounds extra weight and drag as many feet of hose. In an illustrated circular, testimonials are given from persons who used the machine last year.



Little Giant Traveling Lawn Sprinkler.

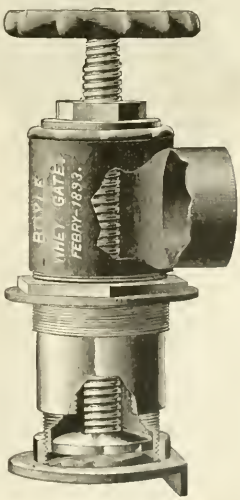
The New Safety Ash Barrel.

The Dover Stamping Company, Boston, Mass., are offering to the trade the new Safety Ash Barrel of their manufacture. This barrel, illustrated in the accompanying cut, is described as having a heavy concave iron bottom, so interlocked with the body that it will remain there as long as the body lasts. At the top and bottom are heavy wrought-iron bands strongly riveted to the body, and wrought-iron outstanding handles of a strength suitable for heavy work. V-shape lateral strips of iron, firmly secured to the body, afford the protection so greatly needed in ash cans, and furthermore remove all danger from fire. The cans are dipped and galvanized after making, to fill all the seams and joints of metal and make it rust proof.

The New Safety Ash Barrel.

The Boyle Whey Gate.

The accompanying illustration shows a broken view of the Boyle Whey Gate, which has been brought out for the Canadian market by Boyle & Son, Napanee, Ont., and which was patented by William H. Boyle. The whey gate closes up to end of pan, and it is pointed out that no curd is wasted, and there is no chance of the white curd getting mixed with the colored. It has an opening of 2½ inches, which will take the whey away very quickly when necessary. It is made short, so as not to protrude beyond the vat, and is therefore not in the way of anything. It is entirely made of brass, with ground valve and valve seat, and no leather or washers are needed. The McClary Mfg. Company, London, Ont., are the agents for the Boyle whey gate for Western Ontario.



The Boyle Whey Gate.

The Abell Coffee Pot.

The Leach Roaster and Baker Company, Paxton, Ill., are introducing the coffee pot as shown in the illustration herewith given. The object sought in the construction of this pot is to have the coffee made in a closed chamber, and all steam condensed before it has an opportunity to escape, the condensed steam being conveyed back to the coffee in form of water. The pot is provided with a fine aluminum strainer to prevent any grounds from being poured into the cup. The strainer is removable for cleaning, and being of aluminum does not rust or corrode. The manufacturers state that the pot effects a saving in the amount of coffee used, that the strength of the berry is saved and used, and that there can be no waste, as the steam is condensed and returned to the coffee. The pot is made in two sizes, medium and large.

The Abell Coffee Pot.

GEO. FRIES' SONS of 909 Filbert street, Philadelphia, makers of Tinware Specialties, are offering a useful line of seasonable goods, including Nursery Refrigerator Kettles, fitted with a movable zinc reservoir for holding ice and a zinc lining so arranged as to allow of ½ inch of air space between it and the outside body; Tin Butter Chests with ice reservoirs, Cream or Egg Whips, Nursery Refrigerators, Tin Lady Lock Sticks for making pastry, Croquet Molds and Window Mirrors. They state that the season finds them well stocked with the different goods and prepared to execute all orders promptly. As their specialties are favorably known, they will no doubt get a good share of the season's trade.

EX-SHERIFF HENRY FREDERICKS, Camden, N. J., who has largely turned the management of his large hardware business over to his sons, has secured apartments at the Boscobel, Atlantic City, where he and his family will spend the summer.

AT THE FIFTH ANNUAL CONVENTION of the Tin, Sheet Iron and Cornice Workers, which was held in St. Louis during the past week, the following officers were elected: President, F. A. Ponchart, Chicago; first vice-president, J. Y. Cross, Denver; second vice-president, C. H. Burton, Richmond, Va.; secretary, Thomas McMaster, Allegheny City, Pa.; treasurer, James H. Horn, Louisville, Ky.

STOVE TRADE NOTES.

Cyrus Carpenter.

At a meeting of the Stove Trade held at the office of the Walker & Pratt Mfg. Company to take action upon the death of the late Cyrus Carpenter, who died April 28, 1893, it was voted that J. M. Read, Wm. E. Smith and George W. Walker be a committee to prepare memorial resolutions, a copy of which should be sent to the widow and to the daily papers for publication. It was also voted to attend the funeral, and close their places of business from 2 o'clock to 3 30 o'clock p.m. on Wednesday, May 3.

IN MEMORIAM.

Mr. Carpenter was born October 9, 1818; died April 28, 1893. He commenced business as a stove dealer in 1841, and was actively engaged in the same line to the day of his death. He was genial, quiet, unassuming, and attended strictly to his own business.

Through all of these years of an unusually long business life, he had become one of the most familiar business men of the city. We shall, while passing here and there upon the streets of the city, miss his courteous and cordial greetings.

To the members of the family we extend our sympathy.

J. M. READ,
WM. E. SMITH, } Committee.
GEO. W. WALKER,

BOSTON, May 1, 1893.

Abram Cox Stove Co.

of Philadelphia are making an exhibit at the Builders' Exchange in that city of their new ranges, hot-air furnaces, combination heaters and hot water circulators. They show a handsome line of their steel kitchen ranges, which they claim will, with fair use and wear, last a lifetime. The line includes a double-oven ten-hole range in a tiled background or setting, having a large hood in connection with a flue ventilator designed to carry off the steam and odors incident to cooking. Considerable floor space is taken up for diaplaying their Ideal Novelty hot-air furnace, designed for the use of hard or soft coal or coke. The grate in this furnace can be instantly removed for repairs or change as easily, it is claimed, as a drawer from a bureau and without disturbing any other parts or the removal of pins or bolts; while when repairs are needed only such parts as may be worn out need be replaced. The company claim for this heater the advantages of freedom from dust, ease of management and great heating power. Prominence is also given to the Ideal Novelty combination hot-air and hot-water heater. This heater, it is stated, will heat by hot-water radiators apartments remote or inconveniently situated for the introduction of hot air. The hot-water section in the heater is cast in one piece, and is, therefore, seamless and proof against leak. All the parts constituting the hot-water arrangement are interchangeable with the plain hot air furnace, so that the combination, when desired, may be effected where the hot-air furnace has alone been used. An excellent working model of their Novelty Circulator for hot water heating attracts a good deal of attention.

The Fireside is the title of an open-front fire-place stove forming part of the exhibit. This stove is intended to heat an upstairs room, as well as the room in which it is located. It can be furnished for a tile setting, or in any style of finish desired. The Novelty Kitchener is also exhibited, and the statement made regarding it is that it is the biggest range for the space it occupies yet put on the market. It is a six-hole range, and is intended to heat an upper or adjoining room without extra cost for fuel. It is made with right or left hand ovens, and has an ornamental case covering the horizontal boiler, to prevent undue radiation of heat, and has a hot closet underneath the boiler. The grate can be removed, when required, without disturbing the lining of the fire box or removing any bolts or nuts.

New Trade-Mark.

Among the stove concerns which have recently adopted new trade-marks may be mentioned the Bain Mfg. Company of

New Trade-Mark of Bain Mfg. Company.

Charleston, Ill., makers of the Monarch stoves and ranges. The design of the trade-mark by which their goods will be designated in the future is presented in the accompanying illustration. It will be seen that the design is suggestive in character, the circular panel in the center carrying a warrior's head, above which is the word "Monarch" and below "Stoves and Ranges." Bordering the design is also the name and address of the company. The features of the design are such as to be readily employed in connection with stoves and ranges, and the device, while being bold and striking, is at the same time unique and distinctive.

A CABLE DISPATCH from Vienna dated April 22 says :

The Chamber of Commerce of Vienna has adopted a vote of thanks to Julius Goldschmidt, Consul-General at Vienna for the United States, in recognition of the Consul-General having used his influence for the promotion of Austrian trade with the United States.

This is a graceful compliment to a well-known member of the stove trade, Mr. Goldschmidt being vice-president of the Brand Stove Company of Milwaukee. We may remark, in view of the early expiration of his term of service, that some of our Democratic friends have been disappointed at the seclection by the President of a successor to Mr. Goldschmidt who is not a stove man. It had been hoped that the precedent thus established in the Vienna Consul-General's office would be followed by the new administration. As there is some chance that the gentleman nominated cannot serve, it may not be too late for the question to be pressed. Now, who wants to go to Vienna for the coming four years? Are there many in the trade who prefer the hardships and vexations of official position to the luxurious surroundings and ceaseless pleasures of American stove manufacturers ?

John Plane and the Acorn.

Rathbone, Sard & Co. have placed in their sample room at Wabash avenue and Randolph street, Chicago, a large oil painting of their first customer in the West—John Plane of Belvidere, Ill. Mr. Plane has been depicted by the artist in the act of expatiating to a customer on the merits of a Royal Acorn heater, which stands near him. It is a life-sized portrait, and represents him as he looks at this time. The size of the painting is 9½ x 7½ feet. It is incased in a heavy oak frame, decorated with oak leaves and acorns beautifully carved. At the bottom is a plate bearing the inscription, "John Plane, the pioneer hardware dealer, who has sold stoves from 1836 to 1893." On the margin of the painting is a view of the Aurora plant of Rathbone, Sard & Co. The artist is a Belvidere lady, Mrs. S. Rhodes Loomis, who was commissioned by Mr. Plane to perform this work, in which she has shown rare artistic talent. Mr. Plane is an enthusiast on the subject of Acorn stoves, and the painting is his own idea, of which he has borne the entire expense. The frame alone cost him $100. It was originally intended to exhibit the painting at the World's Fair, but the arrangement of Rathbone, Sard & Co.'s space was not found well adapted to it, and it was, therefore, given a conspicuous place in the sample room, where it will attract much attention this summer. The Belvidere *Northwestern* of recent date contains some poetry written by a friend of Mr. Plane, and doubtless suggested by this painting, of which we reproduce a few stanzas :

Behold ! the Royal Acorn stove,
The latest and the best
That John Plane ever introduced
To the people of the West.

Which for artistic elegance
And beauty of design,
Perfection and magnificence
All rivals does outshine.

This Royal Acorn parlor stove
All other bids defiance,
For none like it is built upon
A system based on science.

* * * * *

John has for seven and fifty years,
While in the hardware trade,
Sold Rathbone's stoves and testifies
No better can be made.

There are 26 stanzas of this poem, and those of our readers who desire to follow

further the thoughts of the poet should call on Vice President Sard who takes great pleasure in reading it to an appreciative listener. Mr. Plane is remarkably well preserved, and is by no means the venerable patriarch that one would expect to see. He has just retired from active business and has been succeeded by R. F. Tousley.

A Large Lump of Coal.

The following item from an English exchange may interest the stove man who often has to blame the failure of the magazine in a stove to feed to the use of coal of too large size: "An enormous cob of cannel coal intended for the Chicago exhibition, and sent from the Abram Collieries, Wigan, has been shipped at Liverpool. It is said to be the largest block of coal ever raised and weighs over 12 tons. In getting this cob to the surface many men were employed, and it took nine months to hew it out of the seam. It is said that the cost of obtaining it was £1000, or about £83 per ton. When raised the cob was inclosed in a case of planks, the weight of the cob and case being 13 tons 11 hundred weight. It arrived safely at the Alexandra dock and was placed on board the "Philadelphia" by means of ropes and chains attached to four pulley purchase blocks with a 6-inch wire rope span. As a precaution against the masts giving way under the great strain of the lifting gear attached to them, preventive guys were placed fore and aft. The power was supplied by a steam winch on board the vessel. The time occupied in shipping the cob was only 30 minutes.

It is, however, claimed in other quarters that a still larger cob was dug from a Derbyshire pit and exhibited at the first International Exhibition in London in 1861. This piece weighed, it is said, no less than 18 tons. Several large blocks of salt have also been recently shipped from Liverpool from the Cheshire salt district which are destined for World's Fair exhibits. Some of them are skillfully carved with figures representing a cow and dairymaid milking, "Lot's Wife," "Liberty," &c.

ODD PLATES.

The Spicer Stove Company of Providence, R. I., are shipping large quantities of stoves to the West, some going to the Pacific Coast by way of Cape Horn and others overland. We are advised that the Model Grand ranges made by this concern received the highest award at the Mechanics' Fair held in Boston in October last, and that they are in use at the Providence Cooking School. Several important changes have been made in Model Grand for this season, which will be shown to the trade during the month of May. An attractive exhibit of these goods is already set up at the World's Fair.

A. B. Kingsland & Co., Burlington, Vt., have arranged their portable baking ovens for the use of gasoline, as well as wood and coal fuel, and have recently perfected an attachment which enables confectioners to utilize surplus heat from the smoke pipe of an ordinary confectioner's furnace in connection with their ovens.

S. H. Pierce, who has been the mainstay on the road of Warren Foundry Company, Warren, R. I., since their beginning, has given up the management of that concern and joined the forces of the Richmond Stove Company, Norwich, Conn. Mr. Pierce entered upon his new duties May 1.

A. F. Glaessner of the Union Stove Works, New York, has just returned from a trip in Maine, where he not only succeeded in bagging a satisfactory number of orders, but is credited with catching a 15-pound salmon. It is probable that the fish will be stuffed and added to Mr. Glaessner's collection of dead gamecocks in the Museum at Meriden, Conn.

S. H. Plumb of the Stamford Foundry Company, and E. L. Marston of Manning, Bowman & Co., formed the center of a bouquet of traveling men at Boston one evening last week. A number of well-known stove concerns were represented in the bunch, and the flowers, to continue the simile, were daisies.

The Excelsior Steel Furnace Company, 110 South Jefferson street, Chicago, have issued a large folder giving numerous illustrations of samples from the Excelsior line of heating specialties. These illustrate a number of different types of furnaces, showing their interior construction, the arrangement of their grates, &c.; also hot-water boilers and combination heaters. In addition there are shown smoke radiators of several patterns, adapted to ordinary or very strong flues, registers of all kinds in artistic patterns, radiators for steam and hot water, quick-opening valves, gauges, &c. The sheet is a very creditable showing for this enterprising company, although it represents only a portion of their specialties.

Some old stoves that have given long service have recently been removed by E. H. McCann, 61 Lafayette avenue, Brooklyn, N. Y. One, an old pattern St. Nicholas range that had been used 32 years consecutively, was replaced by one of their new Champion ranges. The top of the old range was cast in one piece and showed a crack near the front which had been neatly mended, but otherwise was in good condition. The oven door was of the drop character and the lugs and catches, while giving evidence of much wear and tear were still intact. The other servant of 28 years was a fire-place heater, and from comparison of heating qualities these of the present day have not greatly advanced.

Friends of A. J. Doty, the gas expert, will find him the manager of the Harlem Gas Appliance Exchange, recently opened at 155 West 125th street, New York. The store is well lighted and stocked with a varied line of high-grade goods, displayed with excellent taste.

One of the features of the new gas range just brought out by A. Weiskittel & Son of Baltimore, Md., is an open fretwork top made perfectly flush, so cooking utensils can be readily moved about. The top cooking burners are made in two parts, the upper part lifting off so that it can be easily cleaned.

The March-Brownback Stove Company of Pottstown, Pa., announce in a bright, terse circular of four pages, printed in black and red on enameled paper, one of their newest productions—the Crown hot-air furnace,—"the kind that heats." Before pointing out the strong features of the Crown, they make some very suggestive remarks on "the matter of price" and "the matter of size." These are to the point, as many expenses arise, the company say, "all from one kind of economy," and the safest principle to follow in deciding the size of furnace to use is to select one with capacity to heat the whole house, getting one "with plenty of radiating surface, and with a large fire pot underneath to give capacity," then zero weather will create no discomfort. "The Crown furnaces are built on this principle." The base is of the kind which receives the galvanized casing on a heavy rim at the floor and contains a large, strong ash pit, provided with an efficient dust flue and the Smythe patent triplex grate. A two-part fire pot insures strength and a sand joint insures a tight connection. On the fire pot rests a dome, containing a large fire door, and supporting the top return flue steel radiator, which contibutes a large hot surface and utilizes the heat of the gases. Another strong point alluded to is that it stands low, affording a sharp rise in the heating pipes and a rapid flow of the air. All of the dampers are on the outside where they can be seen and attended to and are so constructed that they can be operated from upstairs by a chain. A cut shows the construction and under it are given the sizes, being Nos. 30, 34, 38 and 42, the diameter of the casing in inches, and the different hights, 56, 58, 60 and 63 inches, with fire pot diameters of 18, 20, 22 and 24 inches, respectively. The last page of the circular shows a cut of the base and the grate.

The increasing use of American gas and oil stoves abroad is apparent from the reports of British consuls in various countries, remarks the *Gas World* of London. Already these stoves are in use in Australia, France, England, Belgium, Canada, Mexico, and, to a lesser extent, in Central and South America, where a growing demand for them is noticed. The United States Consul at Cape Town, South Africa, reports that gas stoves are in use there to only a limited extent, which is matter for surprise, seeing that coal is worth from $15 to $20 a ton, and fire is only needed for cooking purposes. The adoption of gas or oil stoves would, under these circumstances, save quite 50 per cent. in outlay, besides doing away with the heat and worry incident to coal fires. There would appear to be a most promising field for the further extension of American trade in this line of goods in other places similarly conditioned.

The Ridgway Furnace Company of Boston, Mass., favor up with a copy of a neatly printed catalogue of 32 pages, which has just been issued from the press. It relates to the Ridgway revolving open fire pot heater or furnace, and gives a full description of the device, numerous illustrations being presented showing the general arrangement of parts. By far the major portion of the catalogue is taken up with testimonials from those who have used the company's furnaces. These letters come from various sections of the country, and show in a very forcible manner the light in which the Ridgway furnace is regarded by those who have practically demonstrated its merits.

We understand that E. L. Tallmadge, Jr., has severed his connection with the Perry Stove Company and will now devote his attention to the interests of Sam S. Utter. Mr. Tallmadge will visit the trade in New York and vicinity where he has many friends, and who, by reason of his ability to secure orders wherever he goes, have dubbed him "Old Reliable."

The establishment of Joseph Huse & Son, 95–97 Blackstone street, Boston, Mass., is a model of compact arrangement, and it is probable that more business to the square inch is done there than in any other store in the same line in Boston. Upon entering may be found a narrow passage, bounded on one side by shelves filled with stove repairs, and on the other by a bank-like partition, behind which diminutive desks are packed like sardines. Here and there is an irregular opening, which, if followed by chart, leads to the private office of G. H. Huse, who directs, from a seat in the show window, his force of small but mighty clerks. Large men are barred unless they happen to be customers, and for these special accommodations are provided in the rear of the store. In this part of the building the large orders are handled also, and for these ample accommodation has been provided. Mr. Huse's private sanctum is plenty large enough for two, and the visitor, whether he comes to buy or bore, is made to feel

that he fills it completely. This concern make a specialty of repairs, hollow ware, mica, &c., and their quarters resemble a veritable hive of industry.

J. H. HOFFMAN, manager of the Excelsior Hardware Company, 58 Warren street, New York, is just home from Europe, where he has been looking after the gas stove interests of the house who represent in the United States the John Wright Company of England. New vigor will now be infused into the sale of the Beaver and other gas goods which the house manufacture.

ON OPENING a substantial envelope, bearing the inscription "The Novelty Kitchener, made by Abram Cox Stove Company, Philadelphia," a handsome enameled four-page card with gilt edges appears, bearing the inscription in gilt, "What's Inside?" On the first inside page, printed in a silver tint, is a brief description of the Novelty Kitchener. A handsome half-tone engraving of the range occupies the opposite page, and is so printed as to give the full impression of a rich original photograph highly finished. It is one of the now popular horizontal boiler ranges with a low closet, a top hot closet with the boiler lying above it, a drop boiler or feed door, an ash door with ample air opening, and an oven door betokening a capacious oven. The pipe collar gives evidence that its operation will be sure to please if full-size pipe is carried to the chimney, and a hot-air pipe in the oven side shows that a current of air to warm another room will be supplied. On the last page in gilt is the Novelty trade-mark and the words "Compliments of," with a line below bearing the autograph of John P. Ley, the manager of the Second street sales room and the designer of the announcement described.

ACCORDING to one of the St. Louis papers an exhibition was recently given in that city at the rooms of the Electrical Club, designed to demonstrate the practical merits of electricity for cooking purposes. The rooms of the club were ablaze with incandescent lights, while the arrangement of the tables, kitchen utensils, &c., was such as to present a cheerful and homelike appearance.

IN COMMEMORATION of the World's Fair year, the Peninsular Stove Company of Detroit, Mich., are preparing a steel engraving of the grounds and buildings of the World's Columbian Exposition. This engraving is to be distributed as a souvenir to all dealers handling Peninsular stoves, ranges and furnaces; and in order that every one of the company's customers may receive a copy of the picture, they ask all who desire a copy to make application for it. For the purpose of systematizing the delivery of the engravings, the company will send a card to each of their customers applying, and these cards will be duly registered in the company's office. Upon the return of the card to the company, either in person or otherwise, a copy of the engraving will be delivered or forwarded, as may be directed. It is expected that the souvenir will be ready for delivery about June 1.

CONSPICUOUS above everything in its vicinity is the pavilion of the Michigan Stove Company in the Manufactures Building at the World's Fair. This pavilion is in the form of a huge cooking stove, being a reproduction on a mammoth scale of the Family Garland. Its top is 25 feet from the floor, its length is 30 feet, its width is 20 feet, and it stands with each of its great feet on a pedestal 2 feet square and 3 feet high. The under part of the stove forms a gold-lined dome, 20 feet high, giving ample room for the reception and entertainment of visitors. The base and feet of this great stove are finished in aluminum, the body in black, the trimmings in nickel, and the trademark on the oven door in colored glass. The word "Garland" appears on front and rear in large letters, and "The Michigan Stove Company" is on the side below the oven door. These letters are in glass, as well as the trade-mark, and at night electric lights in the interior of the stove will make them visible a long distance. The weight of this great stove is 20 tons, and three freight cars were required to transport its various parts from Detroit to Chicago. It is a most unique and striking advertisement and will certainly attract much attention.

CHARLES E. COLEMAN, with Eugene Munsell & Co., 218 Water street, New York City, is at present traveling through Pennsylvania, Ohio and Indiana, in the interests of the Mica Insulating Company of the address given. Mr. Coleman, we understand, is visiting electric street railways, motor and dynamo manufacturers in the larger cities. He expects to be absent for a month or more, and during his sojourn in the West will spend a few days at Chicago, where he will attend the World's Fair. Mr. Coleman will return in time to visit his many friends in the stove trade in New York State, Western Connecticut and Massachusetts.

F. H. WILLIAMS & Co., general agents at 174 Monroe avenue, Rochester, N. Y., for the superior steel furnaces, combination steam and hot water heaters, stoves, ranges, &c., have issued an announcement under date of May 1 to the effect that they have severed their connection with the firm of Bamber & Williams, and have started business on their own account at the address given. The new concern state that as they have been identified with the commercial interests of Rochester for nearly a score of years, during which time they gave personal supervision to the execution of all work connected with the mechanical or heating department, they are in a position to promptly and satisfactorily attend to the wants of their friends in the trade. The new concern refer to their equipment and facilities as first-class and state that they hold themselves in readiness "to prepare plans and specifications, submit estimates, close contracts and execute all work intrusted to us in a first-class and workmanlike manner."

THE WARREN HARDWARE COMPANY of Warren, Ohio, have issued a circular illustrating the Warren steel range which they claim is constructed upon scientific principles and is economical, durable and convenient. The flues are lined with asbestos, thus economizing the heat generated. The bottom flues are lined with cement, making the case double and adding, it is claimed, to the baking qualities of the oven, while the doors to the oven are double, having between them an air space. The top warming closet has sliding doors, which admit of quick opening, with a passage just wide enough for use, to be used as quickly as may be. The range is referred to as being first-class in every particular and as calculated to meet the wants of a discriminating trade.

F. & L. KAHN & BROTHERS of Hamilton, Ohio, send us an attractive catalogue of 24 pages relating to their Bijou and Peerless gas ranges, for which many strong claims are made. The construction of these goods is said to be such that the burners may be regulated to produce satisfactory combustion under all conditions of pressure and with all qualities of gas; that the burners may be easily kept clean inside and outside by the most ignorant user; that the ranges are made in every size and form called for by any class of buyers, and that the consumption of gas is economical, while the operation of the stove is rapid and efficient. The goods are shown in various styles, together wit the Hotel Peerless and Bijou Estate. Several pages are given over to junior stoves with and without oven, aad-iron heaters, cake griddles, hot-water reservoir, waffle irons and other goods intended for use in connection with gas-cooking apparatus.

SHERMAN S. JEWETT & Co., Buffalo, N. Y., have issued an attractive catalogue showing their line of wrought steel gas ranges, together with other heating and cooking appliances The major portion of the pamphlet is given up to the Jewett range, patented on April 12 of the present year. This range is made with hot-water generator, and is intended for using artificial, natural or fuel water gas. There are eight round improved sheet flame or sawed cap boiling burners on the top, with 8-inch openings for either closed or open griddles. Beneath each bake oven are two oblong baking and roasting burners. A warming oven is placed below the broiling chamber and above the generator chamber, which is heated by the surplus heat from the generating chamber burner. The range has cast-iron top, front, bottom and corner pieces, and steel back, sides and ovens. The sides are lined with heavy asbestos, in order to concentrate the heat in the ovens and prevent radiation into the kitchen. Other features include patent balanced oven doors, draw-out bake ovens, nickel supply gas pipe, valves, pilot lighters for oven and generator burners, mixers, door handles, panels, turn buckles and hinges. The range is shown in various styles and sizes. Other goods include the Jewett gas range and broiler, Jewett gas heater with asbestos flame plate and the Jewett gas range, which was awarded the gold medal by the Pittsburgh Exposition in October of last year.

A FIRST RATE PUBLICATION is the *Garland Magazine*, issued now and again by the Michigan Stove Company. The World's Fair number has just appeared. It is a 16-page pamphlet, with a terra-cotta cover, and the contents are so interesting that if a man doesn't wish to spare the time to read it through he had better not dip into it. There are a few references to Garland stoves and ranges, but they are brought in so happily that they add to the attractiveness of the contents. A pretty song, "School Bells," covers two of the pages. We observe that the circulation of the magazine is put at an even million.

A PHOTOGRAPH just received from the Mount Penn Stove Works, Reading, Pa., shows the Penn Diamond, one of their latest productions. It is a handsome square parlor stove and double heater, which we are informed is of the most modern style and of the highest grade and quality in every particular. In appearance it pleases the eye, the design blending with the elaborate nickel decoration. A handsome name plate reposes above the ash door, with massive foot rest on the side and a deep cabinet base, all of which glisten like silver. The fire pot section is surrounded and surmounted by beautiful open work and a dome with large mica spaces, through which may gleam the rays from the fire. Up on the dome rests an elegant top section, full nickeled and so arranged as to highten by reflection the illuminating effects of the fire. The magazine has a handsome movable cover supporting an ornament of appropriate splendor. As beauty is as beauty does, the internal construction and the essential conveniences are of that character which increases the satisfaction of the owner as the demands made upon the stove become greater.

California's wheat prospects are unusually bright since the recent rains.

New Excelsior Furnace Bonnets.

The Excelsior Steel Furnace Company, 110 South Jefferson street, Chicago, have brought out some special furnace bonnets possessing marked advantages over the usual style of bonnet. They are made with two heads, and the space between is filled with mineral wool. Illustrations are given herewith to show the several styles manufactured by the company, a portion of each being broken away to present the interior construction.

Fig. 1 is a bonnet with straight sides, Fig. 2 with sides pitched at an angle of 60° and Fig. 3 of 75°. These are the stock patterns and they are made of any hight wanted, as indicated by the scale of inches on the side of each cut.

The special advantages of these bonnets, as pointed out by the manufacturers, are the prevention of radiation of heat from the top of the furnace into the cellar, the better distribution or radiation of heat into the pipes, and the avoidance of danger from overheating cellar joists in a low cellar. The top of such a bonnet, it is said, is so cold that it could be put in direct contact with the joists, if that was necessary. The mineral wool used for filling is well known to be a most excellent non-conductor.

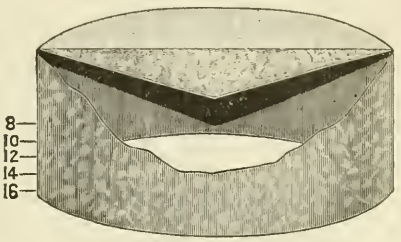


Fig. 1.—Bonnet with Straight Sides.

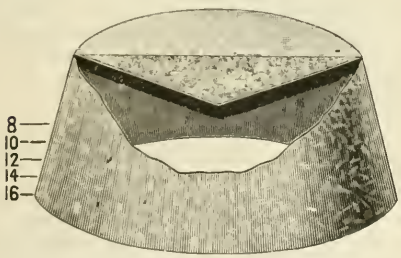

Fig. 2.—Bonnet Having Sides Pitched at an Angle of 60°.

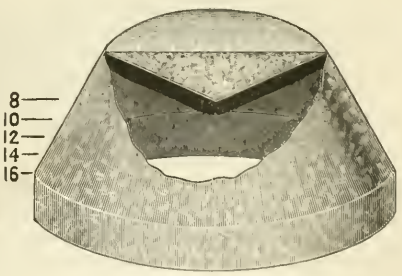

Fig. 3.—Sides Inclined at an Angle of 75°.

NEW EXCELSIOR FURNACE BONNETS.

The J. L. Mott Iron Works.

At Mott Haven, just across the Harlem River, at 133d street and Third avenue, New York, the plant of the J. L. Mott Iron Works is located. Fronting on both streets and running back to a large river front an abundance of light and air is secured, while for receiving iron, coal and foundry supplies and shipping goods the advantages of a water front in a large city are of great value. With the steady growth of a large and varied business many changes became necessary, and under the superintendency of H. Van Atta rapid advances have been made in economy of space and efficiency of plant. During the past year a large building, a portion of the plant erected in 1852, has been torn down to make room for a larger five-story building to be erected this summer, a portion of which will be used as a mounting shop and the balance for storage. A large building was recently built to facilitate the manufacture of their Sunray hot-water apparatus, and on the first floor has been installed specially designed and constructed machinery for that purpose. As these boilers are subjected to a high-pressure cold-water test, it is absolutely necessary that each part and connection shall be perfect to prevent loss in manufacture, as well as the great commercial disadvantage of imperfect goods.

The general machine shop of the works formerly had an independent engine, but by an ingenious use of a rope drive this is no longer necessary, though the engine is ready for use when the main power is idle from any cause. To the hot-air man the heating of the different floors of this part of the plant will be of interest. In the basement is a series of pipe coils, heated by either live or exhaust steam, through which air is drawn by a blower and forced up through the center of the building through a large cylindrical sheet-iron shaft. From this central shaft near the ceiling on each floor a pipe is taken off leading out into the room to be heated, where it divides into three pipes, each shooting a current of warm air in a different direction to warm the room evenly. With the varied character of goods sold by the house in great quantities, the floor space of the foundry is necessarily very large and requires three large cupolas, each charged with a different mixture of irons, and so distributed that the peculiar character of metal required for the different kinds of work is convenient for the molder. The stove department is busily occupied with some additions to their line of ranges which merit the approval of those who have seen them. That portion of the foundry where the heavier work is done is provided with a jib crane and several overhead trolleys.

A great number of plumbing and sanitary goods are turned out every day, in none of which is more pride taken or finer workmanship displayed than in Mott's celebrated cast-iron bathtubs. By a careful selection of irons and a perfect system of patterns and core making the loss in the pipe department has been kept down to a point that is a credit to the management. In the core-making department, where the heavy cores for the large Sunray hot-water apparatus are made, there are trolley carriers running on a system of overhead railways in which there are switches, and which is so arranged that a core can be picked up at any point in the shop and brought to the oven or to the foundry door.

In addition to the iron foundry, a brass foundry for which great claims are made and which shows an admirable management and system throughout is run to make the brass work for the plumbers' goods. In the foundry, which is at the top of the buildings with the necessary core ovens securely protected against fire in a manner worthy of commendation, a fine grade of castings is produced. The castings run down a shute to the cleaning and gate cutting room and on to the finishing shop, where the superintendent has installed many labor-saving machines. Having a nickel plant in every way modern, the plating is kept up to the standard of their goods. As the goods advance toward completion they pass down from floor to floor till they reach the storeroom in a finished state for packing and shipment.

In addition to this plant is a large plant at 137th street and Third avenue under the charge of the Messrs. Lefferts—father and sons—which is entirely devoted to enameling work. After being enameled the tubs pass to the finishers and decorators, where they are finished in keeping with a handsome tiled bathroom, after which they are passed on to the packers, who carefully wrap them in paper and crate them ready for shipment. Under the present management each department charges every other with the goods it furnishes, and yet the system so indispensable in a large business is carried out with no unnecessary red tape.

Work on the Harlem River ship canal, designed to connect the East River with the Hudson, has so far advanced that a steam launch sailed through from Kingsbridge to Spuyten Duyvil during the recent flood. The stone bridge just commenced will cost $348,000.

TRADE REPORT.

The Iron Market.

The past week has seen no improvement in the Iron or Steel trades. This is unsatisfactory, as the fifth month of the year has been reached. A moderate tonnage of Structural Material is being called for, and with favorable building weather during the next few months it is expected that a heavy tonnage will develop. Prices are no worse than they were a month ago, but they are no better, and, for the time being, give but scant promise of being better in the near future. In other respects there is no room for complaint; stocks are light, prices are so low that they cannot be subject to further shrinkage, while the demand is all that ought to be expected under the circumstances. The trade of itself is all right; what is needed is more confidence and easier money.

Pig Iron.—The New York market is dull and the outlook is not regarded hopefully. The general feeling is that the condition of financial affairs will tend to make buyers even more conservative in closing contracts, and may force some furnaces to market occasional blocks at a sacrifice, in order to secure ready money. Southern No. 2 Soft has sold as low as $8.50, Birmingham. We quote Northern brands at $14.50 @ $15.25 for No. 1; $13.75 @ $14.50 for No. 2, tidewater. Southern Iron, same delivery, $14.25 @ $14.50 for No. 1; $13 @ $13.50 for No. 2 and $13.25 @ $14 for No. 1 Soft.

In Philadelphia Pig Iron has got to a price where there is no room for further concessions. A bad break in Iron is regarded as simply impossible, and all that the trade requires is a fair chance to assert itself. Meanwhile sales are chiefly at figures as quoted herewith for Philadelphia and equivalent deliveries, with 25¢ @ 50¢ less on Southern brands at Harrisburg and intermediately to Baltimore:

American Scotch, No. 1X.....	$16.00	@ $16.50
American Scotch, No. 2X... ..	15.00	@ 15.50

The molders' strike in Chicago continues, but there are indications of its early termination. Quite a number of the molders employed in some of the principal foundries have resumed work at the old terms, and it is expected that in a few days the remainder will follow suit. The Pig-Iron dealers have found their trade interrupted to some extent by the strike, but not so much as would have been supposed, as the strike is purely local. High grades of Lake Superior Charcoal Iron, say Nos. 4 to 6, are quite scarce. Inquiries for these grades are coming in from Car-Wheel concerns, and efforts are being made to weaken the market, but makers are firm. Quotations are as follows, cash, f.o.b., Chicago:

Lake Superior Charcoal.....	$16.50 @	$17.00
Local Coke Foundry, No. 1.....	13.75 @	14.25
Local Coke Foundry, No. 2.....	13.00 @	13.25
Local Coke Foundry, No. 3.....	12.75 @	13.00

There is no increase in the volume of business in Pig Iron in Southern markets, and the transactions are mainly in small lots. A few sales have been made of 1000 tons in each instance, but many are from one to ten carloads, and yet in the aggregate they foot up quite a good amount. Some factories say that the volume of business in April was larger than any previous like period. Prices remain steady at $9 for No. 2 Foundry, f.o.b. Birmingham, and although there have doubtless been sales for less it was exceptional, and at points where the difference in freight made up for the concession in price. Quotations are as follows:

Foundry.

Southern Coke, No. 1	$13.25 @	$13.50
Southern Coke, No. 2..... .	11.75 @	12.00
Southern Coke, No. 3.....	11.00 @	11.25
Ohio Soft Stone Coal, No. 1.....	16.00 @	16.25
Ohio Soft Stone Coal, No. 2	15.00 @	15.25
Mahoning and Shenango Valley....	14.75 @	15.00
Hanging Rock Charcoal, No. 1.....	19.00 @	19.25
Hanging Rock Charcoal, No. 2....	18.00 @	18.50
Tennessee and Alabama Charcoal, No. 1.....	15.50 @	15.75
Tennessee and Alabama Charcoal, No. 2.....	14.50 @	14.75

Metal Market.

Copper.—The rumor referred to in last week's report to the effect that a large quantity of Lake Superior Ingot was sold to American consumers at 11¢ ℔ lb has been confirmed. Particulars as to quantity of Copper involved and the prices paid were not divulged, but there is quite good evidence that the contracts represented at least 15,000,000 lb, and that the deliveries run three to six months ahead from May 1. There was a firmer feeling at the close, with bids of 11¢ for Lake Ingot turned down by some producers.

Pig Tin.—Arrivals from London continue heavy and have added still further to the stock in first hands here, without preventing accumulation at that point. According to the data given there was an increase last month of 1213 tons in New York and 156 tons in New York stocks, which, despite a reported decrease of 730 tons in Holland, leaves an unprecedented stock. July delivery was raised to 21¢ on Saturday, but not permitted to drop below 20.80¢ afterwards, cash stock, in the meantime, being held steadily at 20.60¢ @ 20.65¢. Fair average consumption assists in sustaining the market, but careful manipulation is evidently the greater force in preventing prices from weakening under the weight of present heavy stocks.

Pig Lead.—The market has remained in a dull and somewhat feverish condition, with underlying symptoms of weakness. During the period under review some sales were made at as low as 4¢ regular, while official bullion price dropped to 3.95¢. Subsequently single carloads were sold at 4.05¢ @ 4.07½¢, but later on there were free sellers at 4.05¢ and no buyers of round lots at above 4¢.

Spelter.—Western brands delivered here and at common point are now quoted at 4.50¢ @ 4.60¢, with comparatively light offering for either prompt or future shipment.

Antimony.—No change reported. Business moderate and chiefly at former prices, say 10¢ @ 10½¢ for Hallett's, 10⅝¢ @ 10½¢ for L.X., and 10⅝¢ @ 10¾¢ for Cookson's.

Tin Plate.—No improvement reported in the demand for spot stock or future shipments. Supplies here are liberal, with quite good assortment. Prices seem to be a little soft, but show no radical change. Consumers' prices remain unchanged and demand continues about the same.

Coal.

The Coal market is dull in both departments—Anthracite and Bituminous, and no change has taken place within the week. The Anthracite market is construed as being in a waiting condition, pending the Reading reorganization and the part to be acted by Mr. Harris, McLeod's successor. The scarcity of the small steam sizes is almost a famine, caused by restrictions and active consumption, Pea selling at $3 alongside in New York and Buckwheat $2.35, alongside. The trade newspapers last week were widely at fault in stating that the sales agents had made another reduction of 50¢ ℔ ton. What they really did at their last meeting was to make prices at various points West conform to the reductions made in Eastern prices last March. Though varying with the locality the reductions average about 50¢. The Reading issued orders to close 12 to 15 collieries, leaving 35 in operation.

Bituminous Coal is quoted $3.10 alongside in New York for Clearfield and $3.35 for St. George's Creek Cumberland. The advance in railroad tolls in April makes the rate $2 to New York tidewater and $1.40 to tidewater in Philadelphia and Baltimore. At the latter point shipping expenses of 8¢ @ 10¢ ℔ ton are added, according to the quantity of Coal.

A convention representing the railroad Coal miners in Western Pennsylvania met in Pittsburgh and decided not to ask for any advance in wages.

Chicago Report.

Scrap.—Consumers have forced the market lower on Old Material. Dealers' buying prices are as follows :

	Per net ton.	Per lb
No. 1 Wrought Scrap	$12.50	....
Machinery Cast	10.00	....
Malleable Cast	7.00	....
Stove Plate (free of burnt)	7.50	....
Burnt Iron and Grate Bars	5.00	....

Heavy Brass	....	8½¢
Light Brass	....	4 ¢
Pipe Lead	....	3 ¢
Tea Lead	....	2¾¢
Zinc	....	3 ¢
Rubber	....	3 ¢

Anthracite.—We continue to quote carload lots of 12 net tons as follows:

	Egg, Grate.	Sto. and Ch.
Chicago, Ill	$5.35	$5.60
Milwaukee, Wis	5.35	5 60
Kansas City, Mo	8 55	8.80
Council Bluffs, Iowa	8.55	8.80
St. Joseph, Mo	8.55	8.80
Leavenworth, Kan	8.55	8.80
Omaha, Neb	8.55	8 80
Burlington, Iowa	6.85	7.10
Des Moines, Iowa	8.30	8 55
Davenport, Iowa	6.65	6.90
Dubuque, Iowa	6.65	6.90
Madison, Wis	6.85	7.10
St. Paul, Minn	7.85	8.10
Lincoln, Neb	8.70	8 95
Sioux City, Iowa	8.55	8.80
Aberdeen, S. Dak	8.60	8.85

Colorado Anthracite.

COLORADO FUEL & IRON COMPANY.

Denver	$8.00
Pueblo	8.00
Colorado Springs	8.00
Leadville	8.00
Cheyenne, Wyo	10.00
All points between Denver and Missouri River	9.35

BRUCE & COOK, 86-90 Water street, New York, have put in a stock of the leading numbers and sizes of Genuine Charcoal Bloom Galvanized Iron, branded in black and made by the McDaniel & Harvey Company, Philadelphia, Pa., whose advertisement in this issue calls special attention to the leading features of these goods. Bruce & Cook emphasize the fact that buyers ordering this Iron should be careful to specify that they want Iron branded in black, as the price is a little higher than the ordinary Galvanized Sheets branded in red.

THE IRON-CLAD CLOTHES DRYER COMPANY has been formed at Saratoga, N. Y., with a capital of $6000 and the following officers: Deyoe Lohnas, president; A. S. Hays, vice-president; T. S. Estabrook, secretary; C. F. Rich, treasurer; Deyoe Lohnas, A. S. Hays, T. S. Estabrook, C. F. Rich, G. B. Eddy, W. H. Harris and J. C. Hulbert, directors.

FOR THE GREATER CONVENIENCE of their patrons Merchant & Co. of Philadelphia, in addition to their New York house, have opened a salesroom at 584 and 586 Flushing avenue, Brooklyn, where a line of Tin-Plate and Tinners' goods is carried, that is calculated to meet all ordinary requirements.

THE HABERMAN MFG. COMPANY, Berlin Village, L. I., make a prominent announcement elsewhere in this issue relating to their steel enameled ware, in which they call attention to the circular recently issued by the Lalance & Grosjean Mfg. Company in retereuce to a decision of the Circuit Court of Appeals.

CONDITION OF THE

Hardware Trade.

THE CONDITION OF BUSINESS on the whole is fairly satisfactory, though there has not been as yet that increase in volume which was expected with the advance of the season. This is doubtless in part owing to the continued cold and inclement weather which has prevailed in many parts of the country, curtailing a demand which would have otherwise set in. Many manufacturers, jobbers and commission houses report, however, an excellent business, and in some lines there is certainly a scarcity of goods and manufacturers find difficulty in filling orders as promptly as the goods are required by the trade. In view of the condition of the money market some of the large houses are pursuing a conservative policy in regard to credits, limiting their sales to cash transactions to a greater extent than is usual. It is generally admitted that goods are being sold on narrow margins of profit and that it requires special efforts to keep up the volume of business so as to make it compare favorably with other years.

Advices from Chicago.—The Shelf Hardware trade has been affected unfavorably by the stormy weather of the past week. Snow again fell in some portions of the Northwest, and salesmen have been very much discouraged by the continuance of practically winter weather. The volume of business shows considerable falling off since our last report. The change to winter weather has checked the demand for Refrigerators, Ice Cream Freezers, Screen Doors and other summer goods, but manufacturers are only now catching up with the heavy orders which were booked some time since. Wire Cloth is scarcer than ever. Jobbers quote $1.75, but are turning away a great many orders which they find it absolutely impossible to fill. They are endeavoring to take care of their regular trade but find the stock hardly large enough to meet even this demand. Heavy Hardware keeps up remarkably well, considering the unfavorable circumstances; in fact, presenting somewhat of a contrast to the quietness now prevailing in the Shelf Hardware trade.

Notes on Prices.

Cut Nails.—The Cut Nail market is not in a very satisfactory condition. There has been some falling off in the demand, so that the volume of business is at present only fair. A weakness in prices has also been developed, and $1.10 is now named for carload lots at mill, with intimations that in some special cases this figure has even been slightly shaded. The state of the money market has, probably, some effect in producing this condition of things. Small lots from store are quoted at $1.35 to $1.40.

Advices from Chicago.—Specifications on Steel Cut Nails have been coming in more freely the past week, indicating a growing consumption. The enlarged business, however, came from outside localities, the trade in this immediate vicinity having been badly checked by the unfavorable weather. Prices are now down to a point below which they can hardly be expected to go, and manufacturers look forward to a very steady business as soon as the weather is in good condition for outside work. Quotations on factory lots are $1.30 to $1.35, according to the character of the order. Small lots from stock are selling at $1.40 to $1.45.

Wire Nails.—The market continues without open change, the quotation for carload lots at mill being still $1.55, f.o.b., with Cleveland as the point of equalization for the West and Pittsburgh for the East. It is, however, understood that some sales have been made at $1.50, this price being apparently confined to the Pittsburgh district. The demand continues good. Quotations on small lots from store in New York are $1.80 to $1.85.

Advices from Chicago.—New business in Wire Nails is slow on account of the unsatisfactory weather. In the larger part of last week rain feel almost incessantly, absolutely preventing outdoor work. Jobbers are well fixed with contracts and their stocks will have to be worked off before new orders are given out. The most encouraging feature of the situation is the sale and withdrawal from the market of quite a large stock of Nails in warehouse here, which for a time had threatened to demoralize prices. The rates on factory lots are unchanged at $1.62½, Chicago. Small lots are selling at $1.70 to $1.75 from stock.

Barb Wire.—The Barb-Wire market continues without important change and with a fair though not especially heavy demand. We quote $2.45 to $2.50 for Four-Point Galvanized in carload lots at mill. Small lots delivered in New York are quoted at $2 70 for Galvanized and $2.30 for Plain.

Advices from Chicago.—The Barb-Wire trade shows no improvement, conditions remaining precisely the same as last week. Orders are light, but shipments are still fair on old contracts. Factory prices are $2.20 for Painted and $2.60 for Galvanized, while small lots from stock are selling at $2.30 and $2.70 respectively.

Wire Cloth.—There is a continued scarcity of Wire Cloth, and prices are being advanced by jobbers who have stock on hand and also by manufacturers who are in a position to fill orders promptly. In many cases $2 is demanded and jobbers' quotations are fairly represented by a range of $1.75 to $2.

Wringers.—In the Wringer market there has lately been a good deal of competition and some cutting of prices, so that it has been characterized by some irregularity. As a result of this prices on some leading Wringers are slightly lower. The condition of things is reflected in the fact that the American Wringer Company, 99 Chambers street, New York, have recently reduced the list prices of their No. 2½ Universal, No. 10 Keystone and Nos. 2, 2½ and 10 Novelty Wringers to $20 per dozen, instead of $21, as heretofore. It is understood that the

Lovell Mfg. Company, Erie, Pa., and the Peerless Wringer Company, Cleveland, Ohio, have lately been adding considerably to their line of Wringers, and the competition between them and the American Wringer Company has been of late more active than heretofore.

Leather Horse Tie.—This is put on the market by Covert's Saddlery Works, Farmer, N. Y. The list prices for these Ties are $8.40 per dozen for 1-inch, and $10.80 per dozen for 1¼-inch, these prices being subject to a discount of 33⅓ per cent. to the trade.

Lebanon Cake Cutter.—This is made by the Seltzer Specialty Company, Lebanon, Pa. The Cutters liat at 15 cents each, or $1.80 per dozen, and are quoted to the trade at 40 per cent. discount from list, 100 pounds delivered. The Cutters weigh 60 pounds to the gross and are packed four dozen in a case. A sample set will be sent to any address on receipt of the list price.

Lebanon Beater.—The Lebanon Beater, put on the market by the Seltzer Specialty Company, Lebanon, Pa., is listed at 50 cents each, or $6 per dozen. The discount to the trade is 40 per cent., 100 pounds delivered. The Beaters weigh 200 pounds to the gross and are packed two dozen in case, and also half gross if desired.

Baird's Cooler and Aerator.—A. M. Coon, Leonardsville, N. Y., is the manufacturer of this article. It is sold to the trade at $3, subject to a discount of 25 per cent.

Old Rubber.—The following are the current prices paid for Old Rubber delivered in New York:

Car Springs, in ton lots, ℔ lb.	....	@	$0.03½
Rubber Shoes, in ton lots ℔ lb.	....	@	.04
Large Hose, ℔ ton	....	@	9.00
Wringer Rolls, ℔ lb	....	@	.04½
Wringer Wire Rolls, ℔ lb	.01	@	.02
Syringes, ℔ lb	....	@	.05

Old Metals.—The following are the current prices paid for Old Metals in New York:

Heavy Copper	℔ lb	9½¢
Light and Tinned Copper	℔ lb	8½¢

Jute Rope	℔ lb	1⅞ @ 2 ¢
Mixed Rope	℔ lb	¾ @ ⅞¢

Trade Notes.

WE ARE INDEBTED to J. H. & D. Lake Company, Massillon, Ohio, for a serviceable glass paper weight that will prove particularly useful in the summer, when open windows make drafts about a desk and scatter the papers. Incidentally the paper weight directs attention to Friction Clutch Pulleys, Cut off Couplings, Hangers, Shafting, &c., made by the J. H. & D. Lake Company.

A NOTICE WAS ISSUED to the trade by Cordley & Hayes that after May 1 their location will be at 172 Duane St., New York City. The firm, who are sole agents for the Indurated Fiber Ware, recently issued a circular to the trade calling attention to a decision in a litigation against the New York Wood Fiber Company for Infringing the patents protecting the indurated Fiber Ware. Accompanying the circular was a copy of the decree.

THE RIEHLE BROTHERS TESTING MACHINE COMPANY, Philadelphia, Pa., are installing an extensive and interesting exhibit at the World's Fair Columbian Exposition. Among the articles that will be exhibited are a 300,000-lb Vertical Screw Power Testing Machine, with patent electric automatic screw beam; 200,000-lb Horizontal Car-Coupler Testing Machine; 200,000-lb Vertical Screw Power Testing Machine; 100,000-lb Vertical Screw Power Testing Machine with electric automatic beam, besides a very large number of other similar machines. The exhibit will be in charge of J. R. Matlack, Jr., while the exhibit in the Government Building will be in charge of Capt. A. H. Russell.

GEORGE FRIES' SONS, 909 Filbert street, Philadelphia, Pa., make an interesting announcement this week in our advertising columns concerning various articles of Tinware that they manufacture. The illustrations show a variety of goods and descriptive particulars are given.

THE KEYSTONE TINNING WORKS, operated by Cavanagh & Ferrell, are now located at 312 and 314 Oxford street, Philadelphia, where they are fitted for a capacity of about 1 ton per day. They have recently undertaken the tinning of gray-iron castings which has considerably increased their business and insures them plenty of work in lines not before open to them.

RUMSEY & CO., LIMITED, Seneca Falls, N. Y., and 36 Dey street, New York, have prepared a pamphlet treating specially of Pumps of various character for apraying trees and plants. From the fact that it treats comprehensively and gives engravings of many moths and insects that destroy fruit and vegetables, the name "bug circular" is used to distinguish it from their other Pump literature. This house has been developing in Cuba, Mexico and South America, a trade in Pumps especially designed to meet Southern requirements.

A PAGE ANNOUNCEMENT of William Connors, 676 River street, Troy, N. Y., directs prominent attention to various manufactures of his, which include Stove Cement, Asbestos Furnace Cement, Builders' and Roofers' Elastic Oil Cement, besides American Seal Roofing Paint.

THE UNITED STATES IMPROVED STOVE BOARD COMPANY is the name of a concern recently incorporated at Chicago, Ill., with a capital stock of $30,000. The incorporators include Richard J. Hawes, David Goldberg and Jesse Lowenhaupt.

BORSUM BROS., 202 Fulton street, New York, make a specialty of Polishes for Metal and Glass. They are the American agents for the well-known red Putz-Pulver. At their factory in Jersey City they make a variety of polishes, claiming that they can be used on the finest surfaces of gold or silver.

W. R. OSTRANDER & CO. will now be found at 204 Fulton street, New York, having moved across the street to more convenient quarters, where their stock and samples of Electrical, Mechanical and Pneumatic Bells and Speaking Tubes and Whistles are attractively arranged.

R. B. WHITTEMORE, secretary of the American Roofing Company, St. Louis and Cincinnati, is at present on the Pacific Coast in the interest of his company. He reports the outlook as particularly encouraging, and has sent in a number of substantial orders.

I. BREMER, 44-46 Duane street, New York, claims the distinction of being the only manufacturer whose production is confined to articles of Metal, Leather, &c., intended exclusively for the dog. The manufactured articles might be termed dog furnishings, consisting as they do of Collars in a multitude of styles, shapes and sizes, enabling a selection by purchasers of Harness, Locks for Collars, &c., Leads, Bells, Couplings, Boots, Blankets, Combs, Brushes, Dog Baskets, Dog Bracelets, Whips, &c. Collars are now being trimmed with polished Steel, in addition to the customary silver, brass and nickel. A line is also manufactured of attractive Collars of sterling silver for such as can indulge expensive tastes. A recent novelty is a top lock patent Dog Collar so arranged that there is no movement of the lock or swinging motion, thus avoiding noise and the wearing of the hasp. The lock is flat and placed rigidly on a metal loop, which slides over the end of collar, keeping it in place. This lock is made in a number of sizes for small or large collars.

THE LUDLOW-SAYLOR WIRE COMPANY St. Louis, Mo., have secured a contract for an ornamental Iron arch for the Kelley Building, Portland, Oregon, and a large number of brass foot rails for the Tacoma Chamber of Commerce. In addition to this work they are busily engaged on a number of large local contracts.

CHAMPION BLOWER & FORGE COMPANY of Lancaster, Pa., find the recent additions to their plant inadequate to the requirements of their rapidly increasing trade, and have, therefore, decided on plans for an extension of premises to double what they now are. Work will be commenced at an early date, so that toward fall they hope to be pretty well on to completion.

THE PROFUSELY ILLUSTRATED page advertisement of the Deming Company Salem, Ohio, will be of interest to the trade, calling attention as it does to the complete line of Spray Pumps, Nozzles, Appliances, &c., which they are putting on the market. The New York office of the company is at 72 John street, Henion & Hubbell being their general Western agents, at 55 and 57 North Clinton street, Chicago.

BOAS BROTHERS, manufacturers and importers of Adamant Enameled Ware, Hamburg, Germany, announce that owing to the constantly increasing demand for their gray-mottled ware they are removing to larger quarters at 235 Greenwich street, New York, where greater facilities will enable them to fill orders with the utmost care and promptness.

AMONG recently authorized corporations in Illinois are the following: The Kiabel Palace Car Company, Chicago; capital stock, $10,000,000; for the manufacture of railroad coaches and cars and all kinds of railroad specialties and supplies; incorporators, William E. Schrader, Howard A. Baldwin and Frank B. Redington. Brown

Nut Lock Company, Chicago; capital stock, $600,000; for the manufacture of railway appliances; incorporators, Julius C. Brown, J. C. Le Masters and James W. Wilson. The Weber Brothers' Metal Works, at Chicago; capital stock, $30,000; for the manufacture of sheet-metal articles; incorporators, Charles F. Weber, William J. Weber and William Rochlitz. The Chicago Sanitary Vertical Trap Company, Chicago; capital stock, $150,000; incorporators, Joseph Obyne, John F. Mahon and Joseph Mahon. The Safe and Timelock Company, Chicago; capital stock, $200,000; incorporators, N. B. Rees, J. W. Kenevel Calvin C. March and George F. Probst. The Stiles Tin Company of Chicago; capital stock, $200,000; for the manufacture of tinware; incorporators, William Patte. Stephen Stiles and Henry Stiles. The Automatic Time Stamp Company, Chicago; capital stock, $150,000; for manufacturing; incorporators, Warren B. Martindale, John M. Stebbins, Walter B. Pelton and Charles H. Tallmadge. The United States Improved Stove Board Company, at Chicago; capital stock, 30,000; for the manufacture of stove boards; incorporators, Richard J. Hawes, David Goldberg and Jesse Lowenhaupt. Griffin Wheel Company, at Chicago; capital stock, $1,250,000; for the manufacture of car wheels; incorporators, Thomas A. Griffin, Gardner G. Willard and William W. Evans. Metropolitan Electric Engineering Company, at Chicago; capital stock, $50,000; for the manufacture of machinery and electric motors; incorporators, Francis J. Dommergue, Charles H. Fleischer and Joseph Staab. Turnbull & Cullerton Metal Lath Company, at Chicago; capital stock, $50,000; for manufacturing and contracting; incorporators, George A. Turnbull, E. F. Cullerton and N. H. Hanchett. John F. Alles Plumbing Company, at Chicago; capital stock, $60,000; for manufacturing and repairing plumbing; incorporators, John F. Alles, Joseph W. Alles and Warwick A. Shaw. Killmer Mfg. Company, at Chicago; capital stock, $50,000; for the manufacture of water filters and novelties; incorporators, Louis J. Pierson, Edward M. Burst and W. N. Woodson. Tilton Sewing Machine Company, at Chicago; capital stock, $50,000; for the manufacture of sewing machines, equipments and supplies; incorporators, Joseph H. Tilton, Victor T. Eltiug and J. E. Fay. The Goltra Steel Company, at East St. Louis; capital stock, $1,500,000; for a general foundry business; incorporators, G. J. Root, R. J. Whitney and Edward F. Goltra.

The Capital Sheet Metal Company of Columbus, Ohio, capitalized at $100,000, have been incorporated. The object is to manufacture Sheet-Metal products and carry on a general manufacturing business at Columbus. Operations will begin at once.

The Sykes Iron Steel & Roofing Company of Niles, Ohio, have space at the World's Fair, which is located in the north end of the Manufactures and Liberal Arts Building. The space is in Section E, on the gallery floor, and the display is in charge of R. G. Sykes, who, we understand, is a pioneer in the manufacture of iron and steel roofing. The company invite their friends in the trade to make use of their pagoda as headquarters while visiting the exposition. They also extend an invitation to customers to visit their office and works at 611 South Morgan street and inspect their lines of roofing, siding, steel lath, &c. In reaching their exhibit in the Manufactures and Liberal Arts Building the company request visitors to take the first stairway east of the central entrance on the north, and their space will be found the second east after landing in the gallery.

At Cambridge, Ohio, J D. Taylor and others will at once begin the building of the Guernsey Rolling Mill, and the Cambridge Iron & Steel Company are beginning to build an extensive galvanized Sheet-Iron plant.

Morgan & Cornell, New York, issue a circular relating to Plain, Japanned, Stamped and Decorated Tin Cans, Grocers' Fine Canisters, Chinese Scenery Paper and Views and Store Fittings of every description. Illustrations are given of Canisters, Spice Cabinets, Tea Bins, Tin Scoops, Fancy Tin Tea Signs, Molasses, Syrup and Oil Cans, Sample Boxes, &c.

Gummey, Spering & Co., Philadelphia, issue a circular to the trade referring to their tin-plate works, where they are making bright and roofing plates in large quantities. The circular also gives a list of the plates they make, together with prices of different sizes and gauges. They say that they will send a box of their brands to any point east of the Mississippi, and if not satisfactory they will take it back at thei rexpense of freight.

In the United States Circuit Court at Pittsburgh last week the National Wringer Company filed an answer in the suit brought by the Erie Wringer Mfg. Company, through its receiver, A. Y. Smith. The original bill states that the defendants infringed upon the claimants' patent. In their answer the National Wringer Company claim that the Erie concern were sold on January 29, 1892, and the respondents bought the patents after they had passed through several hands, and they claim they had permission to manufacture the Wringers.

On the 19th inst. the residence of La Rue Brothers of the La Rue Hardware Company, at Kansas City, Mo., was destroyed by fire. John H. La Rue and his wife were in the Western part of the State and the inmates of the house, who narrowly escaped, were George A. La Rue, Charles O. La Rue, W. J. Wilder and his son and Annie Nordling, a servant girl, who was overcome and carried from the third floor where she slept. They were not able to save even their clothes. Mr. Wilder the inventor of the aluminum alloy lost all of his valuable papers. The La Rue Hardware Company are general agents of the Aluminum Alloy Metal Company of Hampton, Iowa.

The Cleveland Stamping and Tool Company of Cleveland, Ohio, have increased their capital stock from $25,000 to $100,000.

The demand for the Colliau cupola furnace has encouraged Byram & Co. of Detroit, Mich., to add eight new sizes, making 16 different sizes in all They have recently made shipment to the Ohio Falls Car Mfg. Company, Jeffersonsville, Ind.; the Marion Steam Shovel Company, Marion, Ohio; the Bignall Mfg. Company, Medina, N. Y.; R. S. Newbold & Son, Norristown, Pa.

The Niles Spouting & Roofing Company of Niles, Ohio, have been granted a charter of incorporation, with a capital stock of $10,000.

Friedly & Voshardt, manufacturers of sheet-metal architectural ornaments, are erecting a four-story and basement factory for the manufacture of their goods at 196-198 Mather street, Chicago. The buiding will have a frontage of 50 feet on Mather street and a depth of 115 feet. In the basement will be placed a new tubular boiler and engine, which will furnish the necessary power for elevator, presses and other machinery. They are designing a number of new styles of sheet-metal work for ceilings, which they will not be ready to put on the market until their new factory is completed and some special machinery has been installed.

The Annual Fire Bill.

It is somewhat startling to be told that the average yearly destruction of property by fire in the United States reaches the immense figure of $100,000,000. Still more so, when we stop to consider that this great sum is an absolute yearly loss incurred by the wealth of the nation, that it is so much property completely blotted out of existence. For although some $70,000,000 out of the total is paid through the insurance companies, every dollar of this amount comes, not out of the coffers of the companies or the pockets of the stockholders, but from the policy holders. Now, it is asserted by recognized authorities that the majority of these conflagrations, which are annually taking such a large slice out of the country's means, arise from *preventable causes*. Therefore, it seems a clear case where the proverbial "ounce of prevention" should be brought into active play. Americans are apt to plume themselves upon the excellence and efficiency of their city fire departments, which may here represent the "pound of cure," but little has been done toward the *prevention* of fires, which, after all, should be the first solicitude.

Fire Prevention.

This subject is treated with considerable ability by C. John Hexamer in a paper on "Causes of Fires," printed recently in the *Journal* of the Franklin Institute. Mr. Hexamer is strongly of opinion that the modern lavish use of glass and iron, which is so noticeable in the new store and business buildings of cities, has increased and will still further increase the terrible annual fire waste. The want of care in regard to the paraphernalia of heating, lighting, &c., and its relation to the accumulation of rubbish and the inflammable material stored in these tinder boxes, furnish food for reflection. Looking at the immense hazards run daily in nearly all such establishments it is only wonderful, says our authority, that we have not more fire losses. This, however, is but meager cause for congratulation. Something must be done to remove the main causes of fire. The remedies for the present state of things suggested in the paper above quoted as the only efficacious ones, and which should be adopted without delay, are: 1. A national bureau for ascertaining fire hazards. 2. Better building laws. 3. Inspection and reinspection by faithful, competent and well-paid men. 4. The co-operation of the press in instructing the public in the vital importance of this matter. 5. The supervision and inspection of mechanics erecting heating and lighting paraphernalia. 6. The appointment of a "fire coroner" in all cities, who must be an expert. It is time the public awoke to the importance of this question of fire prevention, of which it is even more ignorant than of matters of hygiene.

One Effect of the World's Fair.

That one effect of the great show at Chicago will be to stimulate trade in American manufactures is a foregone conclusion. This fact is recognized at its true value by at least one of our English trade contemporaries. The *Ironmonger*, in a late issue, contains an able editorial on the subject, in which it warns British hardware men and manufacturers in general that they will have to gird up their loins and strive mightily in order to neutralize the effect of the World's Fair on the minds—and orders—of their former customers abroad. The article roundly asserts that the outcome of the exhibition will be a very marked impetus to the sale of American goods in Great Britain and the European countries, as well as in the British colonies, South America, the West Indies, Japan, and other markets where English manufactures have hitherto held sway. Our contemporary strikes the right note when it says: "The World's Fair will attract an enormous number of visitors from all parts of the earth. These visitors will go with very open minds, for the most part, and it is not unreasonable to assume that they will go somewhat predisposed in favor of that American inventiveness and 'push' of which they have all heard so much. They will be readily impressed, therefore, by all they see, and, as the Americans are doing their 'level best' to make the show the very biggest thing of its kind, all the odds favor the inference that the visitors will return home with many 'Yankee' notions in their minds and a general disposition to be much more receptive than heretofore in relation to American products of all kinds. This frame of mind will naturally highly favor the export efforts of our American cousins, and we may rely upon them to make the utmost of their opportunities both at the exhibition and subsequently."

An Education for Foreign Competitors.

The manufacturers of the United Kingdom are accordingly counseled in the article above quoted to make the most of the opportunities of instruction and the "wrinkles" which can be gained there, by visiting the fair themselves and making good use of the knowledge which, with open eyes and receptive minds, they cannot fail to pick up. They can turn this to good account in the improvement of their own productions, bringing them up to the standard of American goods where through conservatism or lethargy they have fallen in the rear. If this timely advice is acted upon the fair may be made to serve a double end. While primarily, doubtless, benefiting the home manufacturers, it should impel our British cousins to shake off the trammels of old traditions in business and imbibe new notions—"Yankee" or otherwise—which they will doubtless turn to good account. The world's trade should offer a field wide enough for both nations to work in for many years to come without any necessity for skinflint competition or embittered rivalry. We learn that numbers of English hardwaremen and manufacturers are likely to take a run over to Chicago, and the journal above quoted remarks: "No man, unless he is an absolute fool, can visit the United States and return without being wiser in some respect for what he has seen, and the really smart man ought to be able to pick up a sufficient number of wrinkles to much more than compensate him for his outlay and loss of time." We believe that a visit to the fair will be an education to a British—or any other—manufacturer, of which he should have no hesitation in availing himself, if he has any desire to keep or extend his business.

No Time to Advance Wages.

The agitation for higher wages and shorter hours of labor is a curious feature of the existing situation. Labor leaders seem to have no comprehension of the crisis through which the country is passing, but press their schemes as though every industry was enjoying the hight of prosperity. The disturbances in the financial world are wholly ignored, and a deaf ear is turned to all statements of a decreasing volume of business and bad collections on standing accounts. Merchants have been complaining for several months of the slowness with which their customers have met bills, but they looked forward to the opening of spring, when relief was expected from the enlarged movement of farm products. That relief has not come, but on the contrary further discouragement intervenes in the backwardness of the season. Failure after failure has shaken confidence among capitalists, and purse strings are being tightened, which must result in more failures unless a change speedily takes place. Prices of all kinds of manufactured goods feel the effect of the financial pressure, and it looks as though the few articles now steadily held at a good price must come down with the rest. Yet, despite these untoward events, labor demands increased compensation, heedless of the fact that costs would thus be enhanced and reckless of ensuing consequences.

Resources of Employers.

Every workingman knows, if he has the least glimmering of common sense, that the establishment which employs him has a much better chance for continuing in steady operation if its cost of production is lower than that of competing concerns. The concession of higher wages under pressure is often a sign of weakness, and the workmen employed in such an establishment should not congratulate one another too heartily. When the pressure for business is sharp and lower prices on goods must be made to secure trade it is only a question of time until the concerns struggling with highest costs will drop out of the contest. Employers of labor have no mysterious source from which they can obtain an illimitable supply of money to carry on their business. When a man becomes an employer of other men he does not change his condition and cease to be a man, but he borrows in the same way as other men who are not employers, and must pay his debts in the same way or he will speedily wind up his career as an employer. Labor leaders, however, act as if employers were a different order of human beings, with unlimited financial resources, making huge profits in some inexplicable fashion, but always reluctant to divide fairly with those who work for them.

Labor at Chicago.

The very high wages obtaining at Chicago are being used as a lever in other localities. That city, however, is at present in an abnormal condition, owing to the magnitude of the preparations made for the World's Fair, not only inside the exposition grounds, but outside of them. Building materials and labor in the building trades have been at a premium for some time. The high wages thus paid, under the force of circumstances, have made workingmen restive in other lines. Even the waiters in hotels and restaurants have caught the infection, and demand compensation equal to that usually paid to the most skilled mechanics. This is only a temporary matter, however, and in another month the rush will be over. There will then be a surplus of labor, and the hard and fast rules of the unions, to which the members are inclined to give the credit of their high earnings, will have to be ignored in the search for employment. Chicago will surely take an early tumble from its present proud position as the workingman's paradise. The dispersion of the crowds of skilled workmen, by the completion of the fair, may then affect other localities in precisely the opposite manner. It is unfortunate for the workingman, but perhaps inevitable. In view of the troublesome times ahead, labor leaders should act conservatively and restrain their hot-headed followers rather than seek to further inflame them.

Small Power for Small Shops.

The need of power in small shops on special occasions has been too keenly felt to require comment, but the ordinary power plant presents many objections and entails expenses that are unwarranted by the work to be done. With the advent of electric lighting in so many cities and larger towns, the electric motor may prove to many an acceptable solution of the problem. It requires no licensed engineer or fuel, makes no dirt and is always ready, while its management or control is simple and confined to the lever which completes the electric circuit and the switch lever which graduates the current to the work. The cost of the electric plant compares favorably, power for power, with that of plants previously available for small work. When installed for intermittent use, a contract, varying in price with the locality, can, we are told, be made with the local electric company to supply a small power for one-tenth to one-fifth of the cost of steam. Some of the plumbing, metal spinning and machine shops of New York have already adopted the electric motor, and as much of the machinery of the tin shop can be advantageously run by power, it is more than likely that electricity will find increasing favor in that field.

Cleanliness in Shops.

We believe that, all other things being equal, more work is done and larger profits are made in clean shops than where uncleanliness and confusion are allowed to prevail. In a well-ordered shop there is no overhauling of materials to find a particular kind or quality; the hand can be immediately placed upon the thing needed. This saves much more time than is required to put everything in its proper place when it is done with. It also saves loss of the articles themselves. In a well-ordered shop there are no heaps of refuse into which small tools and other small but useful articles, as screws, nuts, nails, pins, rivets, &c., are liable to be dropped and carried out with scrap. In a well-ordered shop everything has its particular place, either on the bench when in use or in some appropriate rack, room or closet, and when wanted for use it will be found in that particular place and nowhere else. In a well-ordered shop the influence of the place itself exerts a beneficial effect upon the men. An example of this is given in the *American Engineer and Railroad Journal*. A visitor to some railway shops found attached to each of them a conservatory, in which were quantities of flowers in bloom, and he observed that some of the men had stuck blossoms in the oil holes of their lathes. The master mechanics of both these shops maintained that an actual saving resulted to the company from the maintenance of these greenhouses, through the cultivation of a spirit of neatness in the men. While perhaps we should be inclined to regard the cultivation of flowers in a shop as rather going to an extreme length, the result of systematic order and tidiness never yet failed to appeal to the best part of human nature, and there is a vast deal of human nature in those who work in shops.

Paris is now supplied with pure water from six springs eighty miles distant, through three large reservoirs, one of which serves as a filter, so that the city is no longer dependent on the foul water of the Seine.

Blessed Be Common Sense.

The simple and effective way in which a mechanical problem, which has proved too tough a nut for ingenious theorists and inventors to crack, is sometimes "accidentally" solved by some one possessed of far less scientific and technical knowledge, but blessed with what, after all, is the greatest of endowments—common sense—is illustrated by an incident related in connection with the discovery of rolling tin foil for tobacconists' use. Some years ago a tobacco manufacturer discovered the superiority of tin foil over paper for wrapping chewing tobacco. There were drawbacks to its adoption, however, in its cost and the fact that it could only be rolled to a certain thinness, beyond which it seemed impossible to go. No rollers could be made to sustain the pressure necessary to render the leaf sufficiently thin to suit the manufacturer. Inventors innumerable struggled with the problem for months and finally gave it up as unsolvable. An ordinary workman about the shop, one day after rolling a couple of sheets to the accustomed thinness, bethought him of putting the two sheets through the rollers again together, and lo! they came out as thin as one; and so the question was solved. It was as simple as is Columbus' egg puzzle and many similar conundrums, after one has seen how it is done. One is inclined to say, "Any fool ought to have known that!" But the fact remains that a large number of thoughtful men had spent brains, time and money over the attempted solution of so simple a problem, and in the end the gordian knot was cut by the "happy thought" of a man who merely exercised his common sense. Instances might be multiplied in which great and epoch-making discoveries were the result of a mere logical following up of an incident, observed accidentally by some one who was happy enough to possess common sense. James Watt and the tea kettle: Isaac Newton and the falling apple; Galileo and the swinging lamp at Pisa, are cases in point which will recur to every one. Through these "accidents" the observers were started on the paths which led to the great discoveries of the law of gravitation and the use of steam and the pendulum, with which their names are inseparably connected. Had either one of them been but a dreamy theorist, we venture to say that the discovery would not have been made by him. But each possessed the inestimable gift of common sense, which, allied with great intellectual power, led to his scientific triumphs. So we say, "blessed be common sense," so called, for the true common sense which is always available and which gives a man correct judgment and ready resource, is by no means a very "common" attribute.

Japan's American trade is increasing, but she buys the larger part of her cotton goods in Europe, where the coarser grades are cheaper.

The Canadian canals this season will have a uniform rate of 10 cents per ton, thus removing all complaints of discrimination against American shippers who transfer cargoes at Ogdensburg, N. Y.

WORLD'S FAIR NOTES.

The claim steadily made by its promoters, that the Chicago Exposition would surpass its predecessors in every respect, has been strengthened by the enormous attendance on the opening day. There were nearly 400,000 visitors present, not counting employees, exhibitors and their attendants and others connected with concessions, &c., whose numbers ran well up into the thousands. It was the greatest day thus far in the history of international expositions. Encouragement has thus been given to the somewhat extravagant expectations which have been indulged in by the people of Chicago who are most directly interested in the success of the fair. The attendance on the following day fell to 14,000 paid admissions, and perhaps doubled this number for the remainder of the week, but that was expected in view of the incomplete condition of the exhibits and the disagreeable weather. Chilly blasts have swept down from the north, and heavy rains have fallen, making a visit to the grounds extremely unpleasant. In some respects such weather has been more welcome than days of balmy sunshine. Attention has thus been diverted from the tardiness of exhibitors, who have meanwhile busily pushed the work of installation. From a general survey this work has made slow progress, and is still far from being complete. Going more closely into details, however, one finds a vast multitude of exhibits in perfect order and ready for the most critical inspection. But their unkempt neighbors detract from their appearance, and until all booths are finished, all exhibits installed and all rubbish is cleared away the visitor will overlook that which is pretty and think of that which is unsightly. The exhibitors are not alone to blame for this tardiness in completing installations. The transportation department on the grounds must take a large part of the censure. A great deal of material has been in the grounds on cars for days, and the utmost exertions of exhibitors have been unavailing to secure the delivery of such cars at the points where they are to be unloaded. The writer has met a number of these, whose experience has been most exasperating. They have lost days of valuable time, merely waiting for the shifting of a car for the space of three or four blocks, and meanwhile hear themselves denounced as a class for hindering the completion of exhibits. In due time these matters will all be straightened out, but it does take time and more of it than had been anticipated. The Director General has ordered that no more exhibits will be received after the 12th, so that at least the end of shipment to the fair is in sight, and the work of installing cannot extend much beyond that.

The W. Dewees Wood Company.

Among the completed exhibits in the Mines and Mining Building is that of the W. Dewees Wood Company of Pittsburgh, manufacturers of patent planished sheet iron. Their exhibit is very striking and most appropriate. It is composed wholly of patent planished sheet iron. In the first place, the inclosure is surrounded by a tubular railing with square posts, very ingeniously constructed of sheet iron. The posts have ornamental caps, surmounted by a nickeled knob. The bars of the railing are made with a lock seam, placed on the under side so as to be invisible. The chief feature of the exhibit is a large column with a square base, on which stand four pillars, one on each corner, with a heavy fluted pillar in the center, supporting a roof, which recedes by gradual rises to a pedestal. Here is placed a large gilt representation of the company's trade-mark—an eagle with outstretched wings triumphant over a prostrate bear. In another part of the inclosure is a rack filled with sheet iron oven doors, stamped in pretty patterns. Stove pipe, stove cylinders, elbows and specimens of plain sheet iron are tastefully arranged near by. A sheet-iron table, of the parlor center table type, is a very interesting specimen of the ingenuity and skill of those who designed this most interesting display.

The Mines Building in General.

While great progress has been made in the installation of exhibits in the Mines Building during the week, much still remains to be done. The official catalogue has been issued, but it is by no means complete or accurate. Reassignments of space have been made within a few days in consequence of some exhibitors having failed to make their appearance. Several foreign countries have just begun the erection of their pavilions. This is very disheartening to Chief Skiff, but he has been unable to control everything. The visitor to the building finds on all sides exhibits covered with muslin, behind which workmen are busily engaged putting affairs in order. Enough is visible, however, to confirm the opinion heretofore expressed that the display in this department when complete will be superb.

The Charge for Power.

The assertion has been made in some of the daily papers that exhibitors in Machinery Hall are complaining because they are obliged to pay for power when they run their machinery continuously. It is rather singular that such complaints should be made now. This whole matter was settled a long time since, and intending exhibitors were advised of the fact that a charge would be made of $60 per horse-power for the whole term. In an interview on the subject last week, Chief Robinson said:

"The question of charging for motive power has been thoroughly canvassed and the basis of rates was established three or four months ago. There was no special committee appointed, but the matter was discussed by the Director-General, Mr. Burnham, Mr. Sargent and myself, and the amount to be charged was then referred to the commission several times for ratification. The result was that the limitation of power was embodied in rule 1 in the classification and rules of the department of machinery, which is as follows:

Exhibitors will not be charged for space; a limited amount of power will be supplied gratuitously. This amount will be settled definitely at the time space is alloted. Power in excess of that alloted gratuitously will be furnished by the exposition at a fixed price. Demands for excess must be made before the allotment of space

"Now this is plain as can be and there is no possibility for a kick. The interpretation of 'a limited amount of power' is the amount of power necessary to turn a machine over to show its workings. The maximum amount under this construction is the amount necessary to turn the heaviest machine. The power is to be furnished at the discretion of the chief to prevent overstraining the shafting. If the exhibitors wish to run their machines continuously they must pay for the extra power used pro rata. If they only need a half horse-power it will cost them $30 for the season. There is no other alternative. This department is not run on a philanthropic basis, but is business, and we expect to make $40,000 or $50,000 out of power furnished. We furnish light and power free to the grounds and big buildings, but the State buildings, individual exhibits and concessionaires must pay for light and power or they will not get it. The exhibits will stay in their places and they will not be covered up, either."

The Question of Sunday Closing.

Although Congress imposed upon the fair authorities the condition that the exposition should be closed on Sunday, the matter is not regarded as absolutely settled, but seems even yet a debatable question. Local influences are being exerted very strongly in favor of ignoring the action of Congress and braving the consequences. At a meeting of the National Commission last week this topic was discussed, and Commissioner Massey said:

"The whole matter, in my opinion, has passed beyond the power of this commission to deal with. The commission had a duty to perform which it has discharged according to the mandates of the statute. I deny that the commission can hereafter lawfully make an order modifying the rule of Sunday closing. When Congress specified the conditions of the $2,500,000 gift and declared that the exposition should be closed on Sunday, it commanded us to pass a rule; and when it made it mandatory on this commission to make a rule closing the gates on Sunday, it limited the powers of the commission in this matter and we are powerless. We can't touch the matter until Congress says so, or until a court of proper jurisdiction shall declare the act of Congress inoperative. The commission is bound hide, hand and foot, and its powers in this regard are absolutely ended. No matter where or how or when the question originates, the commission is powerless to make a rule permitting the opening of the exposition gates on Sunday."

Commissioner St. Clair, who is a pronounced advocate of Sunday opening, and believes that a way will be found at an early day by which an open fair can be secured, made the following declaration:

"When the act of Congress appropriating $2,500,000 to the fair was passed, it had in it the condition that a rule should be made providing that the gates be closed on Sunday, and that if the money were accepted the commission should make this rule. Subsequent to the passage of that act there was in the sundry civil bill the provision that more than $500,000 of the $2,500,000 should be withdrawn and turned over for the payment of awards. Congress therefore broke the Sunday-closing condition, as it took from the directory more than $500,000.

"When the time comes—if it ever does come—for the question to be passed upon, I shall undertake to show that the exposition company stand to-day as they stood under the original exposition act, and that the commission has the power to pass on the question regardless of the act of Congress, as the conditions upon which the mandate was issued has been removed and the mandate is therefore inoperative.

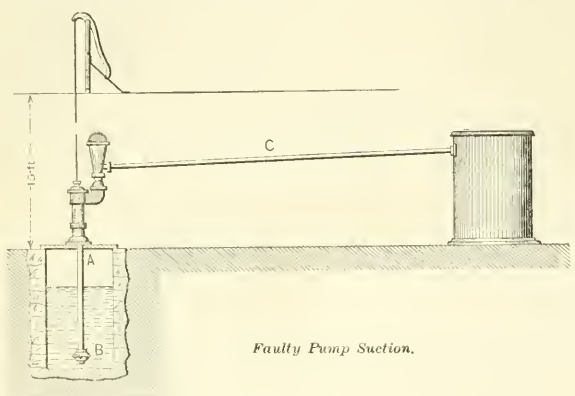
"Under the existing rule of Sunday closing, I am frank to say, the directory hasn't any power to open the gates unless a majority of this commission assent to it, and there is no danger of any attempt being made. If it is made I will exert my efforts, in the courts if necessary, to enforce the present rule."

The commission sustained the position taken by these gentlemen, but it remains to be seen what will be done by the local directory, on whose shoulders the actual burden rests of practically conducting the affairs of the exposition. The impression prevails that in June, if not earlier, the gates will be thrown open, not to be closed on any day until the term of the exposition is ended. It is somewhat significant that the term passes which have been issued contain a coupon for every day in the week, including Sundays, for the entire period.

THE LETTER BOX.

Faulty Pump Suction.

From J. T., *Brooklyn, N. Y.*—In my judgment if "L. R.," Warren, Pa., whose letter about faulty pump suction appeared in *The Metal Worker* of April 1, would place a foot valve on suction, as shown at B in the accompanying sketch, I think his difficulty will disappear, for this reason: The valve will keep in the pipe all the water used by each stroke, and when not in use the suction will always remain full and obviate the necessity of drawing the air out of the long run of pipe each time it is used, and it will also keep the leather valve moist and expanded. That is the difficulty with leather valves; if they are not kept submerged all the time they will soon contract and will be useless for handling air. If "L. R." finds that the foot valve will not give satisfaction he will have to locate his pump as I show in the sketch.



Faulty Pump Suction.

A Variety of Legal Questions.

From E. K. W., *Cleveland, Ohio.*—Please give me information on the following questions through *The Metal Worker*:

If A and wife give a mortgage to C, and A and his wife have a son who is not of age, can C hold this son for it when he becomes of age?

Is there a law to prevent one from marking an article patented if it is not patented, and what is the penalty for so doing?

I see articles marked "patent applied for." Does this mean that application was made for a patent, which was not granted, or has the owner a caveat on it?

What can be done with a person who makes and sells a patented article, the patent of which belongs to another?

Answer.—1. "If A and wife give a mortgage to C, and A and his wife have a son who is not of age, can C hold his son for it when he becomes of age?"

A mortgage is not an instrument of debt in itself. It is given to secure the debt, which is usually evidenced by a bond under seal or by a note. The bond is the most usual obligation given. The mortgage is simply collateral. It is a pledge of the real estate or other property mortgaged and binds all the property covered by its terms. It holds the property, but by itself does not hold any person liable. That object is effected by the bond or note. And the only person liable for the debt personally is the person who signs the bond. No one else is liable. Thus it frequently happens that while both husband and wife always sign the mortgage, the wife to convey her dower right, she does not sign the bond. She cannot in that case be sued for the debt. In this instance the son is not responsible for this debt and it is immaterial whether he was of age or under age when the bond or note and mortgage were executed as long as he does not sign the bond or note. Of course the mortgage remains valid, and if the debt is not paid it can be foreclosed and the property sold. If A and his wife should die and the son become the heir, he only takes the property subject to the mortgage, and it might be taken away from him by foreclosure. In short, the answer to the question is that while the property can be held under the mortgage the son individually cannot.

2. "Is there a law to prevent one from marking an article patented if it is not petented, and what is the penalty for so doing?"

There is such a law. Section 4901 of the Revised Statutes of the United States provides that any person who marks the words "patent," "patentee" or "letters patent," or any words of like import, on articles made or sold by him where no patent has been obtained, is guilty of a crime, and is liable for every offense to a fine of $100 and costs. This may be collected in a suit brought by any person whomsoever, and such person suing is entitled to half the fine. The other half goes to the United States. The action must be brought in the United States District Court. The act also provides that where the name or device used by a person who has obtained a patent is used by a person not having obtained a patent, without the consent of the person entitled to the use of the name or device, the person so infringing is guilty of the same offense and liable to the same penalty. Section 4919 provides that in case of such infringement the court may award damages to the owner of the patent who brings the suit to the extent of three times the amount of the verdict found by the jury. It should be understood that each article thus wrongfully marked constitutes a separate offense and entails a separate full penalty.

3. "I see articles marked 'patent applied for.' Does this mean that application was made for a patent which was not granted or has the owner a caveat on it?"

As soon as an application is made by an inventor for letters patent he is entitled to mark his article "patent applied for." If he continued the use of these words after his application was finally rejected he would certainly be guilty of a moral offense, as it would be a clear case of attempted deception, but there seems to be no criminal penalty for such an act provided by the statute. Where these words are seen it usually means that the proprietor or inventor has made application for a patent, and that the application is still pending in the Patent Office and has not been finally acted upon. The filing of the application gives priority to the person filing it, and the words are used so as to warn others of the claim the inventor makes to the exclusive use of the article, which claim may be good even though the application has not yet been granted, and although the formal letters patent have not been issued. A "caveat" is a secret document filed in the Patent Office, not entered on the public records and not accessible to the public, by an inventor who has not perfected his invention and is not ready to make the formal application, but who desires to obtain priority and to protect himself against competitors or against those who might discover or attempt to steal his invention. The words "patent applied for" are not likely to be used in cases where a caveat has been filed, for the reason that the inventor has not completed his invention so far as to put manufactured articles on the market.

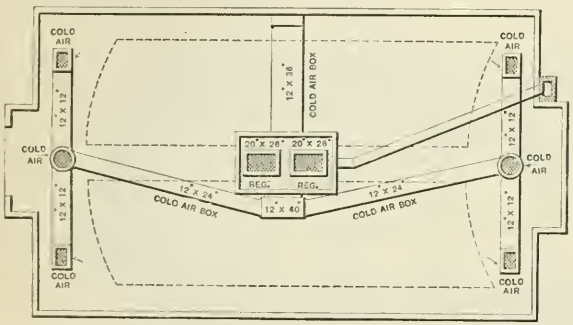
4. "What can be done with a person who makes and sells a patented article the patent of which belongs to another?"

The remedy is an action for an injunction to restrain the offender from continuing to manufacture or sell any of the articles and for damages already incurred. Both these forms of relief can be obtained in one action, which must be brought in the United States Circuit Court in the district where the defendant resides. The

Court usually grants a preliminary injunction if the patent is good on its face, but the owner of the patent must give bonds that in case he is defeated he will pay all damages caused by the injunction. The damages awarded must be proved, and it is very difficult usually to ascertain what the real damage is. The measure of damages is the amount of profits which the owner of the patent would have been enabled to make if his patent had not been infringed. There is no penal or criminal remedy against an infringer.

Warming a Church.

From E. E. DUNNING, *Milwaukee, Wis.*—I was somewhat interested in the letter and plan from "W. D." of Oxford, N. S., on page 40 of *The Metal Worker* of April 15, in relation to a furnace that had been set up in a church, which did not work satisfactorily, and how to remedy the difficulty, also the answer, and as I am sure that there is a much better way to



Warming a Church.—Registers Directly Over Furnace.

arrange this furnace for heating the building, I will give you my ideas of the matter. In the first place, it is necessary that the furnace should have a good draft, as no furnace can work without a good chimney. If the chimney is large enough and not too large (about 8 x 16 is best for this size of wood furnace), and of the same size from top to bottom, without any openings, and up as high as the highest point of the building, there will be no trouble with the draft, although a chimney on the inside of the building is better than one on the outside, for if it is on the outside it is subject to more cold and will take longer to warm up. Taking it for granted that the chimney is all right, I should remove the tin hot-air pipes from the building and place in the center aisle directly over the furnace, as shown in plan, two 20 x 26 warm-air registers and borders, with an opening of the same size, made of brick, from the hot-air chamber up to the registers. I would then use the two warm-air registers in each end of the building for cold air, in connection with the present cold-air registers, by running a 12 x 12 box from each of these two registers into one box directly under the present cold air registers and a 12 x 24 box along the ceiling from this point to the side of the furnace, making such a box from both ends of the building, and connect it in one 12 x 40 box, and run down to the cold-air chamber under the furnace.

In building a box of this kind it is necessary, in order to work successfully, that it be as near air tight as possible, and should be built of dry matched fencing, double, with building paper between. There should be a damper in that portion of the box near the furnace, which damper should be as near air tight as possible when closed. Then build a cold-air box from the out ide, 12 x 36, constructed double, the same as circulating box, and with a tight fitting damper near the outside opening, so that no air can come in from the outside when the air is being drawn from the church and *vice versa*, as it is necessary that one of these dampers shall be closed when the other is open.

This method is not only much more effectual than the one recommended by your answer, but has another qualification of being cheaper. As far as heating the church is concerned, this method I consider equal to any other, although, as far as perfect ventilation is concerned, better results would be obtained by building a new chimney about 4 feet square area inside, for the cold air, with a tile flue in the center for smoke, discharging the impure air into this ventilating flue. But as I am recommending a cure for a furnace instead of setting one in new, I have simply explained what best to do under the circumstances.

Galvanizing Corrugated Iron.

From W. J., *Bay City, Mich.*—I wish to galvanize pieces of common black sheet iron, corrugated, about 15 inches by 30 inches in size and of about No. 26 gauge, which are made up in the shape of shelves. How much tin must I use with the zinc for the coating? What kind of acid is best to remove the scale and what kind of material is best to make tanks of to hold the acid for pickling? I also would like to get some idea of the crucibles or furnace used for melting the spelter.

Crack in Water Back.

From E. E., *Portland, Conn.*—I am at a loss to understand why a water back in a range cracked under the following circumstances. About a month ago the water was shut off the main in street to allow of some repairs being made. After they turned the water on again I went to the house to see if the pipes were all right. I am certain the stops were all open and every pipe and the range boiler were all full of water. We have about 100 pounds water pressure. About an hour later we were notified that water was pouring out of stove and flooding the house. Upon examination I found that the water back had a bad crack and had to be replaced by a new one. What could have caused this? I am sure that it was fully an hour after the water was turned on that the water back showed a leak and it was not caused by the sudden force of water when it was turned on from the main. I would like your opinion on this matter.

Answer.—It is rather a difficult matter from the information furnished us to correctly state why the water back cracked. Numerous causes could be suggested which would tend to such a result under the circumstances, but which is the correct one we could not positively aver. It is possible that the damage to the water back was caused by a too sudden turning on of the water before our correspondent arrived at the house, although the full extent of the damage done did not become apparent until some time afterward, when the fire in the range was started. Or if the fire had not been out at all during the time that the water was shut off, then when turned on again a sudden influx of water would be sufficient to cause the water back to crack under.

Dismissing the foregoing as the real cause and assuming that the water back was sound until after our correspondent left the house, after his first call, it is possible that there may have been some obstructions in the circulation pipes between the boiler and water back, or this may have been present in the water back itself; conditions of which our correspondent may not have been aware of at the time. Assuming that this defect in the circulation allowed the water back to become too hot, then when the colder water was finally forced into it again, by the heavy pressure from the main, the back may have contracted so suddenly as to cause it to crack. We have given the foregoing causes among which possibly is the one to which the cracking of the water back was due.

Cleaning Solder.

From C. W. B., *Fresno, Cal.*—In answer to the question of "A. J. T.," in *The Metal Worker* of April 22, on how to clean wiping solder which has become foul, would say that I have used common salt, in the same manner as described in the sulphur treatment, and think it gives as good or better results. At the same time it does not remind one so forcibly of the place prepared for refractory plumbers. Why use galvanized iron? Why not use brass or black iron nipples, supposing the work to be the connecting of lead and iron pipes?

Sliding Damper.

From L. H. S., *Albion, Pa.*—In reply to "J. C. F." Williamsburgh, Ohio, who wishes to obtain a sliding damper, I would suggest that he take a hack saw and slot about one-third the diameter of the pipe, and slide in the slot a piece of sheet iron. This will serve as a good sliding damper.

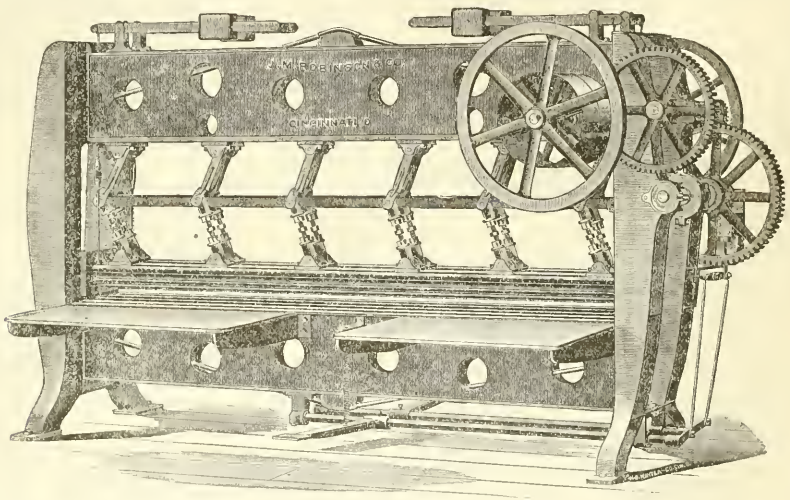
The late Kansas Legislature may be accepted as a fair representative of the Western opponents of alleged "gold bugs." During the closing days of the session that body passed two bills, which received executive approval. The first of them, both being now the law of Kansas, prohibits any lender of money to a person in that State to contract or exact a condition that his loan shall be paid in gold; the second of them provides that any person whose property may be sold under foreclosure of mortgage shall have 18 months in which to redeem it; he during that time to remain in undisputed possession.

The emigrants landing in New York, Boston and Philadelphia excite the envy of Brazil and Argentine, which entice them by offers of liberal premiums. The Southern States, too, hold out strong inducements, especially in sections where the negroes are going to Mexico.

Mexican railroad companies report heavy losses from the depreciation of silver. The Government treasury suffers in like manner.

Sheet-Metal Forming Machine.

The illustration represents a machine manufactured by J. M. Robinson & Co., Cincinnati, Ohio, to meet the demands for forming heavy sheet metal into various shapes required by the trade. It will be observed that the machine is supplied with two sets of gearing, or compound gearing. This is only the case when it is required to form extra heavy sheet metal, such as No. 12 and 14 gauge, into plain figures. With single gear the machine is capable of forming No. 16 gauge and lighter of 12-foot lengths and less. The manufacturers say that under severe test in formiog heavy sheet metal there is no observable spring or giving away. As a single-geared machine, it will work 12-foot sheets of No. 16 gauge, mild steel or iron, and will with suitable dies form V-crimps, corrugations of all sizes in general use, beaded sheets for ceilings, escalloped steel sheets, sheet steel window casing and window sills, clapboards, metal combing caps, fancy or plain, O. G. hanging gutter or eaves trough, half round gutters, metal lathing, inches. Weights are secured to bars with set screws, and are adjustable. The weight bars are fulcrumed to standards secured to the cross beam. To the short end of weight bars rods are secured, the lower ends of which are fastened to the movable slides, thus forming a ballast for the steady moving of the slides. All dies suitable for forming the various figures or forms mentioned are interchangeable and can be worked in the machine. Grooves are provided in the bed and slides for the dies to slip into, and when secured are in line for work.



Sheet-Metal Forming Machine.

Double-Acting Safety Valve.

A. B. Fisher, 385 and 387 Kent avenue, Brooklyn, N. Y., is offering a double acting safety valve, as shown in Figs. 1 and 2. In Fig. 1 is seen the valve as sent out by the maker ready to be attached. Fig. 2 is a sectional view, showing the interior mechanism. The valve is designed as a preventive of explosion or collapse and intended for use in connection with coffee boilers, tea urns or any vessel in which

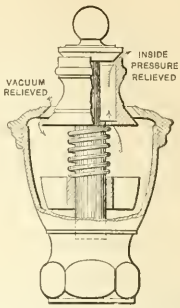


Fig. 2.—Section of Safety Valve, Showing Method of Relieving Inside or Outside Pressure.

sight yields and allows sufficient air to enter to maintain an equilibrium. In the event of abnormal steam pressure, the concealed spring permits of the escape of superfluous steam. This valve may be fitted with an alarm whistle if so ordered.

Double-Acting Safety Valve.—Fig. 1.—Valve Ready for Use.

Fig. 2, the other being inside the tube around which the spring shown is coiled. In case of a vacuum the large spring in

cattle troughs, skylight bars, and other forms for which dies can be used. The weight of the machine is about 22,000 pounds, and of cross beams, 2800 pounds each. These are supported with a cast-iron arch, cast to and as a part of the interior and braced with a heavy hog chain running from one end of the beam to the other, thus securing solidity, which is the main feature in producing good work. The slides to which the traveling portion of the dies are attached are of extra depth and width and are supported by arches and moldings, thus preventing any spring while pressing the sheet metal into the molds. Power is transmitted through gearing on to a shaft, to which are secured cams by which motion is communicated to the horizontal bar. Each toggle is linked to this bar at the knee, the lower end to the movable slides and the upper or stationary end to the top cross beam; thus a movement of the horizontal bar causes the toggles to straighten to a perpendicular and bring a downward pressure on the slides. When the motion of the slides comes to a stop by the action of a clutch movement, it can be continued by the operator with foot pressure on treadle. The stroke of the slides is from 3 to 4

water is confined and heated to a high temperature. There are two sets of springs, only one of which is shown in

---

High prices for pork at the present time, such as have been rarely equaled in the last 20 years, do not result from any scarcity of corn fodder, but rather from the relative increase of pork consumers. It is shown by an array of figures that during the last eight years the number of pork eaters has increased fully 11,000,000, without any increase whatever in the number of those engaged in raising the commercial supply of swine. The result is seen in diminished relative supplies, enhanced prices and a shrinking in the volume of exports

---

Respecting monetary troubles in Australia, the London *Economist* remarks that the telegrams received are so obviously designed to disguise the gravity of the situation that they have only tended to excite distrust. A change in Australian bank practice in several respects is anticipated. The bulk of their deposits being for long terms, only a small proportion of their assets are immediately realizable.

FOUNDRY FACINGS.*

BY HOWARD EVANS.

The time that foundry facing was first invented and the foundry that used it first may be an important fact if we were discussing history. But, as the Foundrymen's Association is looking for information more particularly as to the using of it, we will start under the head of "The reason for its use, what is expected of it, and how it is made." That which is used most is known as bituminous or sea coal, which is mixed with sand, and makes what is known as facing sand.

The object gained by this procedure is to keep the mold from bursting. The hot metal burns out the facing and turns it into a gas, which allows the heated air to penetrate the sand and pass off, leaving the mold in its original shape. This gives form to the casting.

It will be noticed that the escaping gas, after being fired by a torch, burns with a blue flame in the atmosphere, because of the oxygen of the air coming in contact with it and forming a gas somewhat similar to our illuminating gas, which is known as C_2H_4, or four parts of hydrogen and four parts of carbon.

This bituminous or sea coal facing is made from soft coal, such as is used for making gas in our cities and towns. The larger the percentage of bitumen and the smaller the amount of dirt which it contains being important factors, therefore the purer it is the less it takes to perform the object to be gained. In large castings weighing 1 ton or over, made in green sand, it can be used to advantage if ground a little finer than mustard seed, as the escaping air must pass off quickly. In lighter work, such as small pulleys, bench work, &c., this facing should be ground very fine, so the air will escape very gradually and evenly.

As far as the quality of this kind of facing is concerned, there is not so much difference in it, as made in the various mills, as there is in what is known as fine facings. Therefore, bituminous or sea coal facing is only used to mix with the sand. The purer and the larger percentage of bitumen it contains the less amount of it is required, and the better castings it will make.

Fine Facings.

This is where the miller's art excels—in making the proper fine facing. It is made from various refractory materials that will stand the extreme heat in the mold, keeping it from burning into the sand. My idea as to the working of this facing may be illustrated by the following: If one drops a little water on a red-hot stove, he will notice that a bubble is formed which slides off the heated surface. There is an atmosphere of steam between the bubble and the stove. There are various theories expressed regarding the matter, but I think it is a well-known fact that when fine facing is used on the inside of the mold and the heated iron or metal comes in contact with it, there exists immediately an atmosphere between the facing on the mold and the metal which keeps the iron separate from the mold. When the sand is taken from it, it will be found that it has peeled off, leaving a clean surface.

All the best grades of these fine facings are made from plumbago, that which is known as East India plumbago being the best. There is, probably, more of it sold where fine castings of clean surface are required than of any other brand. Other qualities of facings are made from various mixtures, some using soapstone, anthracite coal, carbon, coke, charcoal, fire clay, asbestos, minerals, &c., every mill grinding facing having its own mixture, which is supposed to be a secret. Under ordinary circumstances the finer and more regularly it is pulverized the better, the best grades being bolted through a very fine silk cloth, running about 200 meshes to the inch. In fact, the intention is to make it as nearly an impalpable powder as possible. These facings are placed upon the mold with a bag, slicked with a tool, a camel's hair brush or the hand, and the mold blown off with a bellows, so that there will be none left loose for the iron in passing over the mold to pick up and deposit in some part of the cope, where it might make an imperfect casting. Where it is necessary to return the pattern to make what is known as print work, like stove castings, &c., it is found of advantage to dust on the mold, which has been previously covered with a heavy dust, charcoal or return facings, which prevents the heavy dust of a plumbagenous nature from sticking to the pattern, as the natural dampness of the sand has a tendency to make the heavy dust of a pasty, sticky nature. The charcoal absorbs the moisture and allows the pattern to be taken out of the sand, leaving it clean, and when the metal is poured and taken out of the sand it should have a beautiful, even dark gray or bluish color, making the stove an ornament to the house which it occupies. The making of stove-plate facing is considered an art, as the different shops vie with each other and try to make cleaner castings, of a better color, than their neighbors. The castings must be thin and of a large surface, some of them being only $\frac{1}{4}$ inch in thickness. From this fact it is not necessary to use bituminous or sea coal facing, as the amount of metal used can find vent without its aid.

Another facing, which is used for cast iron water and gas pipe, known as pipe blacking, is used probably more than any other of the fine facings; the large surface to be covered and the immense number of pipes made occasion the great demand. This facing is used as a wash, being mixed with clay water to the consistency of a cream and placed upon the mold. The better grades of this facing, or blacking, are made from superior qualities of coal from the anthracite district, which are selected on account of the large amount of fixed carbon which they contain. Unless it will analyze as high as 85 per cent. of fixed carbon, and less than 10 per cent. of ash, it is not supposed to work with economy or to make clean castings. Most of the large pipe foundries employ chemists to analyze samples from each carload, that they may be sure it is up to the standard before it is allowed to be placed in the foundry. This keeps the facing man continually at work making his selection of coal of a quality that will stand the test, and while coal coming from the same mine is supposed to stand the same analysis, there is nevertheless a considerable amount of difference in the different shipments that are made. The difficulty to contend with in making black wash for making pipe is the liability of it foaming, having an appearance as though it contained a percentage of oil, as it refuses to mix with the clay water. Sometimes a barrel or bag that might be taken from a carload will be found to work in this way, although the facing man has used his best endeavors to make it regular. It is a peculiar thing that the same facing will work differently in the various shops, although they may be using the same grades of molding sand. There are certain secrets in the foundry, and while two foundries may use different secrets in the foundry, and may use different material, they make good work, each having its favorite facing.

The greatest variety of fine facings are found in the foundries making machine castings and general work. Here we find facing with all kinds of names, which leads to confusion. If one will look over the facing catalogues sent out by the different mills, he will find no less than 100 different brands, each of which is to accomplish the same results. It is this that makes it confusing to the foundrymen, and the old saying, that "there is nothing in a name," holds true in fact. It is in these foundries that the greatest variety of work is made. Sometimes very hot iron is required, while at others a slow iron can be used. For that reason a facing that might work excellently well in the shop using slow iron might be inferior in the other using hot, as the hot iron is more searching, and burns through the facing and sand. This is a very important matter and must be taken into consideration. It is necessary, as a rule, to use hot iron, as it makes a clean, sharp corner, but foundrymen must bear in mind that a superior quality of both sand and facing should be selected to stand it.

Some years ago solid facings—that is those made from one material, such as lead, charcoal, anthracite, mineral, &c.—were used, but of late years, in order to keep pace with the times, it has been found necessary to make mixtures of different materials of a refractory nature, which are adapted to the various kinds of castings made, according to the size and shape. In other words, foundrymen cannot expect to use one facing to suit all classes of work. It is not an unusual thing to find a half-dozen different brands in shops making machine and jobbing work.

I visited a foundry a short time since where East India lead of a pure quality was being used. The foreman reported that he was obliged to turn it down, for the reason that it washed and made scalds on the castings. Upon investigation we found the molder worked upon the principle "if a little was good, more was better," and he actually had at least $\frac{1}{4}$-inch thickness of the facing on the cope side of the mold. When I called the foreman's attention to it he directed the molder to make another mold, using the same facing in smaller quantity, being sure to have it well slicked and blown off with a bellows. After the two castings were poured, the one having too much facing on was ruined, while the other was perfect. In this case, therefore, it was not the fault of the facing, but of the molder.

As an ending to this subject, it will be well to remember that it is not always the facing that is at fault. It is sometimes the iron, sometimes the sand, sometimes the atmosphere, that causes the trouble, but I believe that, after all, the molder who uses it has more to do with the successful working of the facing, in making clean castings, than any other element.

* An address before the Foundrymen's Association, May 3, by Howard Evans of J. W. Paxson & Co., Philadelphia, Pa.

How are our cherished delusions shattered by hard historical facts! It appears that the "John Bull" engine, which recently made the trip from Jersey City to the World's Fair, was neither the first locomotive run in the United States nor the first one imported from England. The *Railroad Gazette* tells us that another engine, the "Stourbridge Lion," arrived in New York from England in May, 1829, two years before "John Bull" touched these shores; while in 1830 no less than three American-built locomotives were turned out—the "Best Friend," the "West Point" and the "Tom Thumb." Probably, however, "John Bull" is the oldest engine now in existence in this country.

The tremendous floods of the last five weeks have delayed seeding and other agricultural preparations to such an extent that a "late season" will be a common complaint in many lines of business for some time to come.

ROOFING AND CORNICE.

The Country Cornice Shop.

VII.

By Cornice Worker.

MOLDED GUTTERS ON BRICK WALLS.

Fig. 53 is another form of molded gutter for brick wall, showing the method of fastening it to the wooden wall plate B. A represents the brick wall, B the wall plate, and C the rafter upon which the roof boards are fastened. It will be noticed that part of the molding, from P to E, drops down over the wall, and that the top bend of the molding has an angle iron inserted at H

After the detail of the molding is made, draw a section of the angle iron in the top edge, as at H, also marking the position of the bolts through angle iron, shown at 1 and 8. Now draw the top flange and lock of the molding, making the top flange as wide as shown at F, so that the bolt 8 passing through the angle iron will have plenty of play room to pass the lock J; or, in other words, the lock J should be placed at such a distance from the bolt 8 that the gutter lining can be locked into the lock J, without interfering with the bolt. When making the detail of the inside brace, care should be taken that it meets the angle iron at 1, and the length of the brace at X X should be such that when the plank L is laid upon the portion of the brace from X to U it will come directly under the lock J; in this way, when the gutter lining is locked into the molding the seam can be pounded down tight. The other portion of the brace should meet the molding as shown at 2 and 3, then back to the wall plate with an angle bent upward and nailed to the wooden plate at 6 and 7. The small angle at 4 and 5 is intended to keep the drip molding tight against the wall, without nailing or defacing the molding. The angle should be fastened to the main brace by means of a bolt, 4, and then bolted through the flange of galvanized iron at 5. The hole 5 should be countersunk, so that a smooth surface is obtained. Care should be taken in bolting the angle 4 5 to the main brace that one is exactly like the other, otherwise the drip molding will not lay even against the wall. The length of the stove bolt which is inserted into the hole 5 should not be greater than the inside width of the member Y of the drip molding.

CONSTRUCTING AND PUTTING UP THE GUTTER.

After the molding is formed and set together to the required length the angle iron is held in position with hand vises, as explained in a previous chapter, until the top bolts are all inserted from the bottom up, as shown at 2, Fig. 55. After the top bolts are all in place and the nuts fastened the front bolt 1 is placed through the molding, angle iron and brace and fastened on the inside; the bolts are also inserted at 2 and 3, Fig. 53, and the angle bolted to the main brace at 4, being careful to have the distance from the angle 4 5 to the angle 6 7 the same as the distance from the front of the wall to the wall plate B. The angle irons and braces can all be put in the molding in the shop. Let us suppose the molding is 28 feet in length, in which there are ten braces. In hoisting up on the wall two ropes would be required, looping and fastening each rope on each side to the third brace from the end and tying around the the highest point, it being blocked up with wood, as explained in a previous chapter. The gutter is then lined with either tin, copper or galvanized iron and locked into the lock of the molding at J,

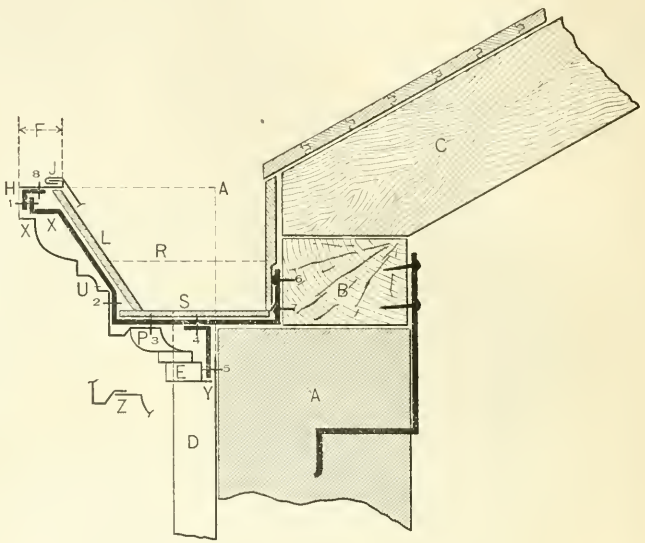

Fig. 53.—Fastening Sheet-Metal Molding Against Wooden Plate.

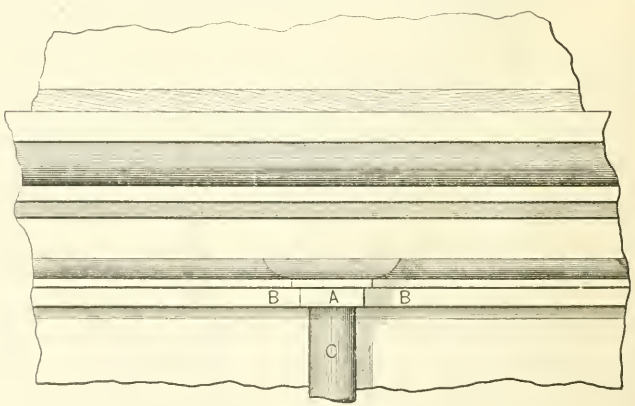

Fig. 54.—Front Elevation of Molding, Leader and Head.

THE COUNTRY CORNICE SHOP.

brace X, Fig. 53. When the molding is up set it on the wall, and drive two anchor nails into the wall plate B at 6 and 7, thus drawing the drip Y tight against the wall. The gutter is now lined with wood by the carpenter, S being the lowest point and R Fig. 53. In Fig. 55 is shown a part of Fig. 53 reversed, with the top brace bolted to the angle iron and screwed to the roof board. At 1 is shown the bolt, passing from the outside through the molding, angle iron and brace and fastened on the

inside. In putting on the top brace, shown in Fig. 55, care must be taken when loosening the nut of the bolt 2 that the bolt does not fall inside of the molding. To prevent this lay a strip of wood on to the part of brace X X, Fig. 53, before the gutter is planked, to uphold the bolt 8 when the nut is loosened. After the top brace is bolted at 2, Fig. 55, screw to the roof planks, as shown by 3 and 4. This top brace will keep the gutter from bending down from the weight of the snow and ice. In milder climates, where the snow is not considered, the top braces could be omitted.

Let D, Fig. 53, represent a square leader, meeting the lowest point of the gutter S as shown by the dotted lines. To make a turn miters are required in the molding, two flat heads, shown at A and B, Fig. 56, are placed on each end of the molding. As the water is to run to the center of the building, the leader will be placed at O, Fig. 56, with a projecting leader head to the hight of the drip molding, the face of which is shown in Fig. 54 at A, and the projection in Fig. 53 at P and E.

OBTAINING THE PATTERNS.

To obtain the patterns for the flat heads for the moldings, proceed as follows: In line with the wall shown in Fig. 53, draw a dotted line as shown from 5 to A', and at right angles to it draw a dotted line, H A', meeting the top bend of the molding H.

At right angles to D A, Fig. 57, draw the line A J. Take the distance of the top flange D F in Fig. 57 in the dividers, and placing one leg on the point J, strike an arc intersecting the line F G at G. Draw a line from A to G, which will be the miter for the top flange of the head, mitering with the top flange of the molding at right angles in plan, shown by 1 A B or A B 2 in Fig. 56. At right angles to F G, Fig. 57, draw G I, which completes the patterns. Allow lugs as shown.

For the pattern of the leader head proceed as follows: Draw a duplicate of the profile of the drip molding, shown in Fig. 53, at A, Fig. 58. Divide A into a number of parts, as shown. Now draw any perpendicular line, as B C, upon which place

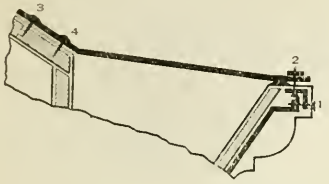

Fig. 55.—Part of Gutter with Top Brace.

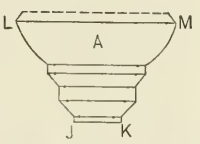

Fig. 60.—Pattern for Face of Leader Head.

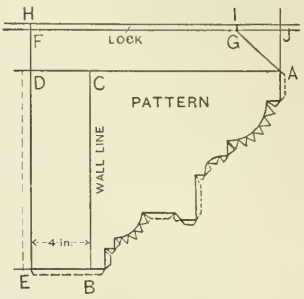

Fig. 57.—Pattern for Flat Head.

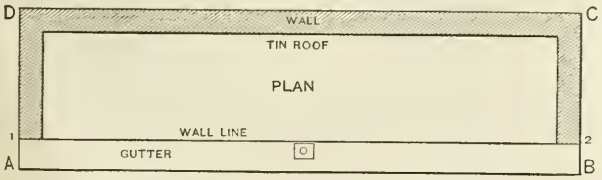

Fig. 56.—Roof Plan, Showing Leader and Gutter.

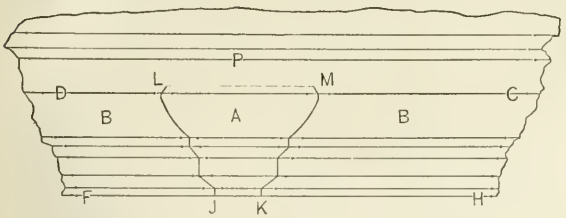

Fig. 59.—Laying off the Miter on the Sheet.

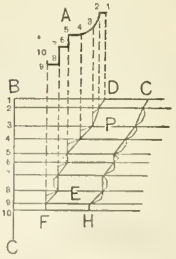

Fig. 58.—Pattern for Return on Leader Head.

THE COUNTRY CORNICE SHOP.

neat finish where the leader D cuts through the drip molding, a small head is made for the leader, having the same projection as the leader D, as shown by P E. Fig. 54 is a portion of the front view of molding, leader and leader head, the section of which is shown in Fig. 53. B B represents part of the drip molding, A the leader head and C the leader.

Having now explained the method of construction, as shown by the front and sectional views, we will proceed to take the measurements and obtain the patterns.

OBTAINING THE MEASUREMENTS.

Let A B C D, Fig. 56, represent the plan view of a tin roof, showing the brick walls and the molding on the front from A to B. O represents the section of a square leader, shown in Fig. 53 at D, and in Fig. 54 at C. When measuring the length of the molding, measure upon the wall line from 1 to 2, Fig. 56. As no re-

Transfer this angle, including the profile of the molding shown in Fig. 53, upon a piece of galvanized iron, by placing the galvanized iron underneath the detail of the molding, and pricking through by means of a scribe awl and hammer. The result is shown in Fig. 57 by A B C. In pricking through the profile on detail, it is best first to divide the profile into a number of parts, so as to obtain the stretch out, and then prick through these divisions. As the molding usually is made to represent stone after being painted and sanded, and as stone work always shows the bearing upon the wall from the side view, it is well to add 4 inches or more to the pattern of the flat head, as shown from D to E in Fig. 57. Now take the stretchout of the top flange of the molding, shown from H to J in Fig. 53, and transfer it as shown by F and G, Fig. 57, at right angles to A D; and add the lock as shown from H to I.

the stretchout of the profile A at right angles to the line B C, and from the small figures draw lines indefinitely, as shown. From the divisions obtained in the profile A drop perpendicular lines intersecting the corresponding numbers drawn at right angles to the stretchout B C. A line traced through these intersections from D to F will be the required miter pattern. Now take the distance of the projection of the leader, shown at D, Fig. 53, and with the dividers measure the distance from the miter cut D F, Fig. 58, on the lines 1, 2, 3, 4, &c.; trace a line through the points, as shown from C to H. Then D F H C, or P and E, will be the pattern required for the projection of the leader head shown by P E, Fig. 53.

In Fig. 59, B, A and B represent a sheet of iron, on which part of the bends of the molding have been lined, as shown. Let us suppose that, the length of the molding having been obtained, the leader will

come in the position on the sheet shown by J K. Now use the pattern P E, Fig. 58, and place the point F, Fig. 58, upon the point K, Fig. 59, placing the line F H of Fig. 58 upon the line K H of Fig. 59, and draw the miter line shown from M to K. Now have J K, Fig. 59, the width of the face of the leader shown at C, Fig. 54. Reverse the pattern P E of Fig. 58, and place the point F upon the point J. Fig 59, placing the line F H upon the line J F, and mark the miter line shown from L to J. As the projection of the leader head comes out as far as up to the line P, Fig. 59, when the molding is formed, we can add a small lap, as shown from L to M, to the pattern A of Fig. 59. Now, taking the right-handed snips, cut out the pattern A of Fig. 59, commencing at the point K, on the miter line up to M, over to L and down to J.

A in Fig. 60 represents the pattern for the face of the leader head which was so obtained. It will be noticed that the face A of Fig. 59 and 60 has no lap attached, the same being the case with B and B of Fig. 59. For this reason laps have been added to the pattern for the return on leader head, shown at P and E in Fig. 58. The miter cut, C H, Fig. 58, is joined to the cuts M K or L J, Fig. 60, and the cut D F, Fig. 58, to the cuts M K or L J, on the sheet B B, Fig. 59, when setting together.

FORMING.

In forming the leader head, use the ridge and gutter former for bending the curves and the hatchet stake for making the square bends. As the profile of the molding shown in Fig. 53 is rather complicated to bend in one piece on the brake, it is better if we make the molding in two sections, as shown at Z, Fig. 53; soldering the two sections in the corner of the drip, using the gutter tongs to make the drip Y and the hatchet stake to make the lock J.

Solder for Roof.

From M. A. D., *Neenah, Wis.*—Which is the best solder to use for roofing, half-and-half or a solder containing a large percentage of lead?

Answer.—Experiments have been tried with the two kinds of solder, and seams soldered with the best quality could be bent a greater number of times without cracking than those on which a coarser grade of solder was used. As a result of the experiments one would infer that seams joined by means of half-and-half solder would be less liable to crack than when a poorer grade was used.

Trouble With a Roof.

From J. M. S., *Platteville, Wis.*—We have a roof with about 6 inches fall in 20 feet. We have put on a felt roof and also one of tin in the last five years. The roof is in such condition that we will have to put on another one at once. We have thought of tearing up the roof and making it steeper, but this would incur quite an expense. One cause of the roof wearing or giving out is that we have to shovel snow off of it. The shoveling and walking on it wears it. Now if we could get something substantial we would like it. We wish to know if you can tell us of any roofing or cement that will answer our purpose.

Answer.—We would suggest the use of a heavy iron or steel roof as more suitable to the requirements of our correspondent. In all probability the bulk and weight of a cement roof would prohibit its use in this case though it has some qualities peculiarly adapted for it. A good plan to protect a tin roof, so that it will not be injured by walking over it or damaged shoveling off snow, is to build an open covering over it of boards 1 inch in thickness and 6 inches wide, laid and fastened side by side, about 1 or 2 inches apart, to cross strips. These keep the boards up from the tin and will allow plenty of air to circulate under and around the boards to dry them after rain. The suggestions given may help to provide something satisfactory or bring out further ideas from other readers.

Circular Gutter.

From M. A. D., *Neenah, Wis.*—What would be the proper way of laying in a circular gutter; sides and bottom in separate pieces with seams at the corners, or would it make a better job to lay each sheet across the gutter with seams pointing toward the center of circle?

Answer.—Providing the radius was such that the sections could be put in the full length of the tin, and the same method was to be used in either case for joining the sections, it would appear that the second method would be preferable, as seams would be avoided at the corners.

FLASHINGS.

WE HAVE RECEIVED, with the compliments of M. H. Crittenden & Son, Minneapolis, Minn., a copy of a very neat memorandum book, or combination diary and calendar, which they are distributing to the trade. On the dark colored covers is the name and address of the firm, and the statement that they give attention to cornices and skylights, as well as all kinds of steel and iron roofings. The first page of the book is intended for the name and address of the owner, and also for the name and address of the person to be notified in case of accident or serious illness of the owner. The next page is intended for data of various kinds, relating more particularly to matters which are easily forgotten, yet the knowledge of which is often valuable. Following a number of blank pages ruled for addresses we find a table giving the population of the largest cities in the United States, some interesting information about the weather bureau and the signals employed to designate the direction of the wind and the kind of weather likely to be expected, rates of postage, &c. There is also a calendar for the year 1893 and one for 1894. Another interesting feature is a list of antidotes for poisons and directions what to do in case of accidents.

I. S. THORN of 1227 Callowhill street, Philadelphia, cornice and sheet metal work manufacturer, is incorporating with his factory an annex 114 x 24 feet. He will enlarge his plant by the addition of new machinery and expects to be running in a short time with a considerably increased capacity.

THE CONTRACT for sheet copper for roofing and cornices on the Pennsylvania Railroad's new train sheds at Broad street station, Philadelphia, has been awarded to Randolph & Clowes of Waterbury, Conn. The roof alone takes 125,000 pounds of cold rolled sheet copper.

THE VULCAN CO. of 1227 Callowhill St., Philadelphia, are putting on the market the cornice machines and other tools controlled by the company. Up to the present time this machinery was only supplied to members of the company. They are now making arrangements for the appointment of territorial representatives who are to place the machinery in the hands of responsible parties. They will shortly issue a catalogue descriptive of their machinery and their plans for doing business.

THE NILES SPOUTING & ROOFING COMPANY of Niles, Ohio, have been granted a charter of incorporation, with the following incorporators: L. W. Sanford, Jacob Holzbach, W. Y. Sayers, C. A. Williamson, M. J. Flakerty, L. Holloway and E. L. Baynton. The officials of the new concern are as follows: Jacob Holzbach, president; W. Y. Sayers, vice-president; L. Holloway, secretary, and L. W. Sanford, treasurer. The firm will engage in the manufacture of the Harris patent lock joint for eaves, and will make a full line of noncorrosive spouting and metal roofing.

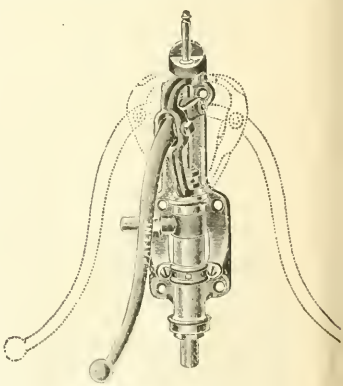
LEO J. SCHLETZER & CO., 52 Point street, Providence, R. I., distribute posters printed on tinted paper, showing various designs in sheet metal work for roofers. The illustrations presented show cornices, skylights, a large number of finials with and without weather vanes, crestings, eave troughs, &c. The firm do copper, tin and corrugated iron roofing, and are agents for Cortright's metallic shingles.

J. M. ROBINSON & CO., Cincinnati, Ohio, report the demand for sheet metal working machinery as being excellent, several orders for large and special machines being now under way, while the demand for the Globe cornice brake is also good.

IT IS STATED that the Guernsey Rolling Mill of Cambridge, Ohio, will erect a sheet mill with two stands of finishing rolls, the product of which will be used exclusively in the manufacture of roofing by an identified local concern.

Johnson's Improved House Pump.

The Lehner-Johnson-Hoyer Mfg. Company, manufacturers of plumbers' brass goods and supplies, 68 to 74 West Monroe



Johnson's Improved House Pump.

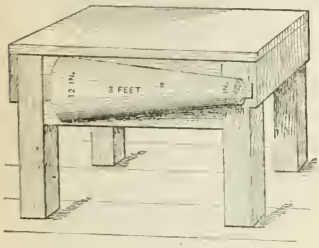
street, Chicago, are introducing to the trade Johnson's improved house pump. As will be observed from an inspection of the accompanying engraving, the pump is provided with a swivel handle so that it can be used in any position. This is a feature which will commend it for use in many locations.

The weight of a million English gold sovereigns, newly minted, is 10 tons, 14 hundredweight, 15 pounds. A million pounds' worth of fresh-coined silver pieces of British money weighs over 151 tons.

THE TIN SHOP.

Former for Wash Boilers.

From S. J., *Paterson, N. J.*—I send you a sketch of a useful former for a tin shop, and which is better than most of the devices for forming oval wash boilers, because it can be put in at any desired point of diameter to allow for difference in quality of the tin, some being more soft than others and consequently forming more closely to the roller. After the boilers are wired lay them on the bench, wired side up and ends even, and mark off the guides for forming them up as follows: With a mark on the wired edge mark a dozen or so together. For 7-inch boiler, 8¾ inches at each end and 16 inches at center; for 8 inch boiler, 9 inches at the ends and 17½



Former for Wash Boilers.

at center; for 9 inch boiler, 9¾ inches at ends and 19 at center.

They are then put in between the back of the roller and the bench and formed to the mark. An allowance for the seam is made by marking the ends ¼ inch more than half of the center space. Use such a portion of the former as will give the following sizes for the boilers when formed:

7 inch.....10 inches wide, 19 inches long.
8 inch.....11 inches wide, 21 inches long.
9 inch.....12 inches wide, 23 inches long.

For the information of any one who is not familiar with the work I will add that

7-inch boilers are of 2⅛ sheets, 14 x 20,
8-inch boilers are of 2¼ sheets, 14 x 20,
9-inch boilers are of 3 sheets, 14 x 20,

or boiler plates of same dimensions.

When finished, and the covers are fitted, any little variation in proportion can be easily adjusted. This roller will give a better view of the mark than the ordinary shop roller and allows quick hauling in and out.

The former will be found useful for many other kinds of work. It can be turned from hard wood about 3 feet long and 6 to 12 inches diameter and fastened ½ inch from bench by iron plates at the ends.

Venetian or Bent-Iron Work.

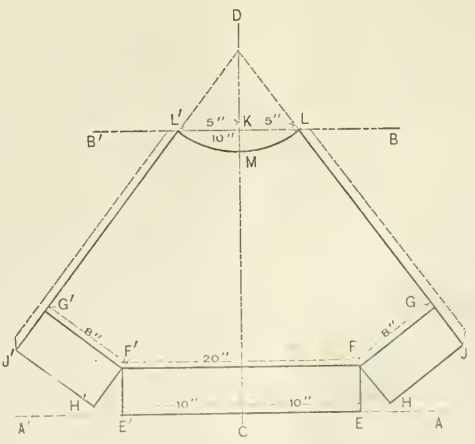
From B. T. N., *Albany, N. Y.*—Indulging in the boyish enjoyment of gazing in the show window of a store which catered to the ambitious amateur artisan of varied taste, my eye caught the above title on a pamphlet. It lay in the midst of examples of that work as designed for ornament and use, which further attracted my attention, and on closer examination I concluded every tinner would be more or less interested if a description could be given, even though no more thorough than can be made on so superficial a study of it. It seemed to me that the principal article used in the manufacture of the pretty things was nothing but narrow strips of tin varying in width from ⅛ inch upward. They were formed into designs embracing scrolls, hearts, arrows, doves and all sorts of objects. These designs were worked into candle holders, lamp-shade frames, photograph frames and stands, and to the ingenious artist there is no limit to the use of this delicate and graceful character of ornamentation. The tin strips had received a coating of some lusterless black, which is in keeping with that employed in coating the grills and irons, umbrella stands and any other heavy ornamental wrought-iron work, which is quite a fad at the present time.

Every tinner in squaring his sheets accumulates more of just such material than he knows what to do with, and it seemed to me that it might be profitably marketed to the ladies, who are interested in all sorts of fancy work, if the necessary trouble was taken to secure a few designs and make up a few samples to show what could be done with the pile of narrow strips of tin that occupied a place in the show window beside them. A neat card to explain something of how the work was done, and that only a few cents would buy the strips necessary and a pair of small pliers to bend and fasten them in place to produce the ornaments exhibited, would be all that would be required to attract attention, and the outlay would amount to very little to the tinner.

The parts are fastened together by wrapping a short piece of the narrow material around the two parts to be secured and pressing it tight with the pliers; all of the other work can be easily done with the fingers. It gives the tinner an opportunity to show that high art is not all confined to the stoves in his store, but that art work can be done in his shop with the refuse of his work, and if he desires many pretty things can be made to sell or to please his wife and adorn his home.

Pattern for Chimney Top.

From I. T., *Joliet, Ill.*—In *The Metal Worker* of March 18, "L. N. H.," Milroy, Pa., asks for a short and simple rule for describing the pattern of a chimney top oblong at the base and round at the top. The method I use is convenient, and appears to be just what "L. N. H." requires. For example, take a top that is to be 20 x 16 inches at the base and for a 7-inch round pipe at the upper end. In the accompanying diagram let A A′ represent the bottom of sheet, and B B′ the top. Draw the center line C D, making it perpendicular to A A′. As the largest side of the top is to be 20 inches, set off 10 inches on each side of C, and from the points thus obtained erect the perpendiculars E F and E′ F′. From E set off the distance cap is to lap on chimney, and draw F F′ parallel with E E′. As the top is to be for 7-inch pipe, having a circumference of 22 inches, make L L′ less than half of circumference, as 10 inches. Then take the half of small



Pattern for Chimney Top.

side of cap on tongue of square (in the present instance 8 inches), and place the square with the 8-inch mark at F, the blade at L, and draw F G D. In a similar manner draw F′ G′ D. Extend D G, and make G J and F H equal to F E, then draw H. J. G′ F′ H′ J′ is to be drawn in a similar manner. With D as center, and D L as radius, strike the arc L M L′, thus completing the pattern. Edges to be allowed for joining as indicated by the dotted lines. Then two pieces similar to L′ M L J H E E′ H′ J′ are required for the top.

Six Mexican Governors are expected to visit New York this month and arrange for a permanent exposition of Mexican products at Industrial Hall on Lexington avenue.

The Foundrymen's Association

The regular monthly meeting of the Foundrymen's Association was held at the Manufacturers' Club in Philadelphia, on Wednesday the 3d inst. In the absence of the president the chair was occupied by Walter Wood, of R. D. Wood & Co., Philadelphia.

The Railways and Freight committees reported progress.

The Executive Committee made a general report on the progress of the association and the benefits which had resulted from its meetings. The report instanced the valuable information derived from the addresses of Mr. James Wister, on "Coke," and intimated that addresses on other subjects of interest to foundrymen would be delivered at subsequent meetings of the association. On the subject of prices the committee referred to the present low prices of castings in open market. This state of things it considered to be brought about by bad guessing and overproduction. The number of foundries had increased in greater proportions than customers for their products. The lowest ebb had probably been reached and there would be few foundrymen start in the future, the chance of gain being so limited. It could therefore only be a short time before the foundrymen would stop the production, and then when one concern had more orders to fill than capacity for filling, it was fair to suppose that future orders would be taken at higher prices. Cast iron was used as much to-day as ever, and the present price of steel castings was so low that it was only a little higher than the price of cast iron.

The treasurer reported the balance in hand to be $365.55.

R. A. Register of Register & Sons, Baltimore; L. B. Whitney of A. Whitney & Sons, Philadelphia, and E. E. Brown of E. E. Brown & Co., Philadelphia, reported progress of their respective sections of the Price Committee.

The secretary announced with regret the decease of two members of the association—Wm. H. Green of the Vulcan Iron Works, Chester, and Edmund Grinnell of the New Bedford Iron Foundry, New Bedford, Mass. These, he stated, were the first members of the association removed by death. Mr. Green had attended nearly all the previous meetings of the association and was personally known to most of its members.

The secretary read communications from Cleveland, Ohio, Grand Rapids, Mich., and other sections, expressing appreciation of the objects and aims of the association and the interest taken by foundrymen in the West in its proceedings, and asking for information with a view to the formation of similar associations as subsidiary organizations. The correspondence evoked much discussion.

H. L. Mumford thought some scheme for centralization of the subjects and matters discussed at the meetings of this and other associations should be promoted, so as to be generally available to all interested. He believed that debates on previously arranged subjects could be conducted simultaneously at the different points.

The chairman suggested that it would be well for the other associations to send the papers they proposed to consider at their meetings to this association, that the ideas promulgated might be further discussed and disseminated. He thought great value would attach to a centralization committee which would take charge of the different branches and thus forward the extension of the work of this association. He would be glad to have the question thoroughly discussed and a committee of sufficient size appointed to keep the movement going throughout the country.

L. B. Whitney thought that before a committee could be appointed it would be necessary to secure the co-operation of the branches, and in that way hold them closer.

The chairman was of the opinion that the subject necessitated a good deal of consideration. He thought it would be advisable for the sections proposing to form sister organizations to send some one to represent them at a future meeting. After further discussion Mr. Mumford moved that the following invitation be sent to the promoters of other associations:

1. The awakened interest in foundry matters is evidenced by the formation of numerous local societies throughout the country for the discussion of foundry practices.

2. The Foundrymen's Association, with an idea of centralizing and making more mutually available and valuable to the foundrymen of the whole country, and especially to the various organizations now formed and forming among them, the most advanced ideas of foundry practices, proposes as follows: That at the next regular meeting of the Foundrymen's Association of Philadelphia in June, 1893, its members will discuss the plan of laying out a line of topical discussion to be jointly carried on by foundrymen in their various local organizations all over the country, and regulated, perhaps, by a committee. The idea is suggested of having the discussions carried on at different places simultaneously and then embodied in a publication which shall be in a sense a nucleus and bond between the various organizations and a return of value for membership dues. That each organization be invited to contribute their views on the plan, either by letter or by personal representation at the meeting mentioned.

3. That in this way the foundrymen of the country may be virtually united in a common interest.

Your earnest co operation is solicited.

The motion was carried unanimously.

Howard Evans of J. W. Paxson & Co., Philadelphia, then read a paper on "Foundry Facings," which we publish elsewhere.

The appreciation of the meeting was expressed in a vote of thanks to Mr. Evans, and an interesting discussion on the paper followed.

Asked by the chairman how far refractory materials like soapstone were used, Mr. Evans replied that all materials used in fine molding were of a refractory nature. Lime was used very sparingly, as it was found to affect the eyes and the pores of the skin. It was used to a certain extent by some of the country founders, but they had to abandon it eventually. It was also used to a small extent, as a mixture. Magnesia was not used to an extent greater than found in plumbago, coal or any mineral, and was not at all necessary. Asked how much ash there should be in a good facing, he stated that in facing for pipe work there should not be over 8 per cent., but 2 or 3 per cent. was about the correct quantity. Coal for making facing was bought by analysis, and vast differences in the analyses of shipments were experienced, which occasioned much trouble. Eighty per cent. fixed carbon, 8 per cent of ash, and the balance water, was the analysis usually expected.

The chairman, in speaking of pipe blackings, remarked that a peculiar circumstance noticeable in their preparation was that at times they absolutely refused to mix with the clay water or molasses, and when placed upon the mold the blacking would not adhere, and the iron picked it up and carried it along. He was told of a good plan for mixing it satisfactorily. In pipe shops it was a usual thing to have a cask of water mixed with the clay, and to dump a full bag, or large quantity of blacking into it, and endeavor to mix it. The mixture was occasionally, after a long time, effected; and sometimes was not effected at all. The surest and quickest plan was to make a paste with a small quantity of the blacking, and lead it up from that point to the consistency of cream, by adding more water and facing. In this way a nice black wash was to be secured.

Asked whether there was any extended use of gas-house carbon in the way of facing, Mr. Evans said that it made a very good wet black for bell molds and pipe where the iron falls a long distance. It had more of a body to it than the anthracite. A number of foundries used it in the bell molds. A trouble in connection with its use was that carbon, which had been bought at $6 or $7 per ton from the gas works, had advanced very much in price, owing to it being used largely by electric light plants for making their pencils. It was now about $12 per ton, with a probability of its going to $20 during the year. The electric light plants were trying to get it all. Petroleum carbon, the residue of the oil works, was also being used, and its price had gone up from $6 to $8 50 per ton.

E. E. Brown stated that his firm had discontinued the use of gas house carbon, as the supply was so very irregular. They had not yet decided what they should substitute for their high heats. A more vigorous blast was a thing to use very sparingly.

The discussion then turned on the subject of high heats, with a view to having some information on it forthcoming at the next meeting of the association.

Wm. Wark of Dienelt & Eisenhardt of Philadelphia stated that he would probably bring to the next meeting a sample of fine molding, the equal of which he thought he could defy any molder in Philadelphia to produce. It was made by a Frenchman in dry sand, and probably the members present would hardly credit the fact of its being made in sand.

R. A. Register and Mr. McCarty of the Pond Machine Tool Company also took part in the discussions.

Regarding the rumor that soil pipe was being freighted from Besemer to Baltimore at rates only 5 per cent. advance on pig iron rates, Mr. Register stated that he had not been able to get freight bills in his possession, and that he had been informed that the railway would not answer any questions on the subject without production of a freight bill to substantiate the charges that such rates were being made.

The meeting then adjourned.

The pernicious effects of holding back the wheat crop in hope of realizing higher prices are spoken of by a Toronto correspondent, who refers to the fact that the grain thus kept in warehouse can now be sold only at the lowest price in two years; that meanwhile other sources of wheat supply have improved the opportunity to sell, and that the money which might have been realized would have mitigated, if not wholly averted, the financial stringency that has already proved ruinous to many whose business was too widely extended. On the other hand, free shipments of wheat to markets already well supplied might have precipitated and intensified the decline which has taken place. India effectually checkmates the United States in any scheme to squeeze consumers in Europe.

The Mannlicher system of magazine rifle has been adopted by Austro-Hungary, Germany, Italy, Holland, Bulgaria, Roumania and Brazil. France follows the Lebel system; Belgium, Turkey and Chili the Mauser; and England the Lee-Speed system of repeating rifle.

THE RETAIL STORE.

National Time Register.

The National Time Register Company, Columbus, Ohio, are putting on the market the register shown in the accompanying cuts. As will be seen in Fig. 1,

Fig. 1.—National Time Register.

the machine has two dials, one above the other, with a push button between. The uppermost is a paper record dial and the lower one a metal designating dial. The record dial, which is behind a glass door

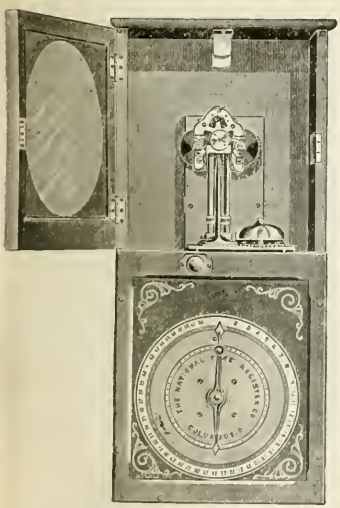


Fig. 2.—Door Open and Record Dial Removed.

securely locked, revolves on the hour post of a clock movement, thus making one complete revolution in every 12 hours. It is divided by radial lines (from center to edge) denoting time, and concentric lines (circles around center) $\frac{3}{32}$ inch apart, the latter being numbered from one up, to designate the employees, each of whom is given a number, the numbers commencing with one. Thus each employee's record is shown in one of these circular concentric spaces, by itself, and, it is stated, cannot possibly be confused with any other. Extending from the lower edge of the space in which this record dial revolves to near its center are guide arms, between which the dial moves. These guide arms, it is explained, support a moving oblong block, equipped with a puncturing point, so arranged that when the push button is pressed a small hole is made in the paper dial as it moves between the guide arms. The metal designating dial is exposed to the operative, and has numbers corresponding to the concentric spaces on the record dial, ranged consecutively around the edge; and a metal pointer or hand, swung from the center of the dial, can be moved by the operative so as to point to any figure on the plate. The movable block containing the puncturing point is connected by simple mechanism with the designating hand on the metal dial in such manner as to work in unison with it. Thus when the hand is turned to number 21 the block moves up along the paper record dial to space number 21, when, by pressing the button, a small hole is made in the paper dial at that point and signifies that employee number 21 has registered. The point is made that the record dial is always moving with the hour post of the clock, and being properly set when put on, the radial lines show the exact time at which the puncture is made. A new dial is placed on each day and the old one, containing a complete record of the time of the employees for the day previous, is filed away under lock and key for future use if necessary. This is accomplished by opening the register door, as shown in Fig. 2.

When the push button is pressed a bell is automatically tapped once, so, it is remarked, any attempt to register twice can be easily detected; that it is absolutely impossible to make more than one record at a time, and that the mechanism is so adjusted that the record is made at the instant the bell taps, thus controverting the excuse of an attempted register. Thus the employee makes his own record, but cannot favor himself one minute.

In Fig. 3 is shown a small portion of a record dial, illustrating the appearance of the record. Employee No. 1 is recorded in at 7 05, No. 2 at 7, No. 3 at 7 08, No. 4 at 6.55, No. 5 at 6.51, and so on.

If the employees have uniform hours a glance at the dial will tell if they are practically on time. From a closer examination the exact time of any individual or individuals is seen, no matter what hours they keep.

The manufacturers claim that the register is simple, durable, accurate, easily and rapidly operated; that it keeps the time of employees paid by the hour by mechanical means, thereby rendering mistakes impossible and preventing favoritism; also that the time of men doing piece work is kept in the same manner, and that these results are obtained with the least possible machinery and at a minimum cost.

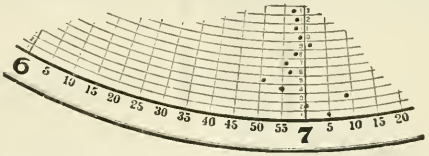

Fig. 3.—A Portion of the Dial.

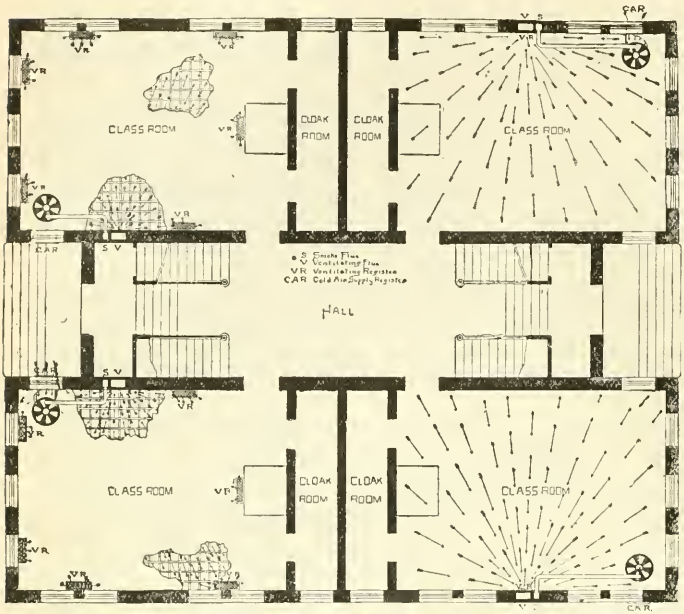
The Utility Oscillating Washer.

The accompanying cut represents a washer put upon the market by Olds Wagon Works, Fort Wayne, Ind. In this machine the washing is accomplished through the medium of compensating springs, as, it is stated, the load in the machine itself furnishes nearly all of the power necessary to operate it. A washboard is combined with the machine, attached to the under side of the lid, which is designed to be used for rubbing extra-soiled portions of the clothing, which, it is remarked, effects a saving of one handling of the clothes, thus combining in one machine a washing machine, washtub and washboard.

The Utility Oscillating Washer.

The Grossius System of Heating and Ventilating Buildings.

A system of heating and ventilating buildings, especially school houses, for which strong claims are urged, is that being introduced by John Grossius Sons, 389 Main street, Cincinnatti, Ohio, and which is illustrated by means of the accompanying cuts. Fig. 1 represents a plan view of a school building, through the center of which extends a hall, while at the right and left are four class rooms, there being two on each side of the corridor. Taken in connection with Fig. 2 of the cuts, which represents a sectional view through the building, very little description is necessary to make the operation of the system readily understood. In the first place, as soon as the fire in the heater is started the smoke passes to the flue S, thereby heating the 4 inch brick partition between the smoke and ventilating flues. The heat rarefies the air in the ventilating flue, marked V on the plan, Fig. 1, causing the air in it to ascend. This air is replaced by foul air taken from the floor of the room through the ventilating register V R. The Grossius patent school room ventilating heater, employed in connection with this system, is supplied with fresh air from the outside, and moderately heated before it is discharged into the room. The ventilating flue, being heated by the passage of the products of combustion through the smoke flue, is said to exhaust the foul air in the room, and thus create a steady circulation as well as a constant change of air in the room. The construction of the flues is a feature to which special attention is invited on the part of the company, the position being such, as stated above, that the passage of the products of combustion through the smoke flue tends to heat the air in the ventilating flue. The smoke flue, the company state, should not be less than 8 x 12 inches in size, while the other should not be smaller than 12 x 12 inches in order to produce the best results. The outlets for the foul air may be arranged in two ways, as represented in the sectional view, Fig. 2. The method designated System A shows the plan of exhausting air from several registers in different parts of the room. Space under the floor may be utilized as a duct to the ventilating flue by stripping the joists with 2-inch strips and on top of these laying the floor. System B shows how the ventilating register is placed at the line of the floor. The company state that by the method here employed each room may be heated and ventilated separately, thus rendering it unnecessary to heat the entire building when it is wanted to heat only a few rooms.



The Grossius System of Heating and Ventilating Buildings.—Fig. 1.—Plan View.

The Cuban sugar industry is concentrating itself into a small number of large estates. In 1868 there were near Santiago de Cuba 129 sugar estates. Now the number is 17, and gradually dwindling, although the aggregate yield of sugar has not fallen off in volume in the last 25 years. The new imposts and Government regulations in Cuba are said to be likely to seriously affect the sugar industry in the island, and great dissatisfaction is felt. The cultivation of coffee and cocoa is reported to be on the increase, while that of tobacco remains stationary.

St. Joseph Pump Company's Fair Exhibit

The St. Joseph Pump Company, St. Joseph, Mo., have erected their exhibit in Agricultural Hall, and, taking into consideration the large number of manufacturers who were unable to obtain space for their exhibits, the enterprise shown by this firm is commendable. The space allowed this concern was secured simply on the merits of the Perfection Elevator and Purifying Pump which they manufacture. The exhibit will occupy a space 10 x 16 feet. The company have erected a platform 7 inches in hight, which is covered with a pleasing design of moquette carpet, and inclosing their exhibit is a double railing of antique copper and brass, shaded from a light to a dark finish, which is soft and effective in appearance. The four corner posts are artistically carved, and on the top of each post are acorns finished in bronze. The front posts are 10 feet high, and are connected at the top by a large bar, suspended from which is a glass sign, containing in gilt letters the firm name and the names of the officers and directors. To the right of the entrance to this exhibit is a base 4 feet square by 2 feet in hight, on which is erected a cistern, made of a combination of hard wood and plate glass, which will permit of the inspection of the process by which the Perfection Pump purifies foul water. The wood work of this cistern is finished in pure white, and the decorations consist of marine and landscape scenes, relieved by artistic drawing in pure gold leaf and ebony. The cistern will hold 80 gallons of water, and above it is erected one of their full-sized Perfection Pumps, also made of hard wood and plate glass, handsomely painted in delicate pink and decorated with gold and bronze. This Pump is operated by the full-sized family chain, and will be constantly in motion, thus showing the effect this Pump has on foul water, whether in well or cistern. To the left of the entrance will be found a *fac-simile* of the pump just described, only miniature in form, which will be placed on the desk occupied by T. W. Moore, the company's representative who will have charge of the exhibit. Around these two principal exhibits are placed a number of full-sized Perfection Pumps, painted and decorated and finished equal to that ordinarily given the finest piano. The railing inclosing the exhibit is festooned with chain or buckets used in the Perfection Pump, which tends to relieve the plain appearance of the railing.

Fig. 2.—Sectional View.

Taking into consideration that a pump at best is difficult to exhibit, the St. Joseph Pump Company have made an excellent showing, and they will, no doubt, be repaid for the time and expense devoted to it. They invite the trade to visit their exhibit and promise to make it pleasant for all who call

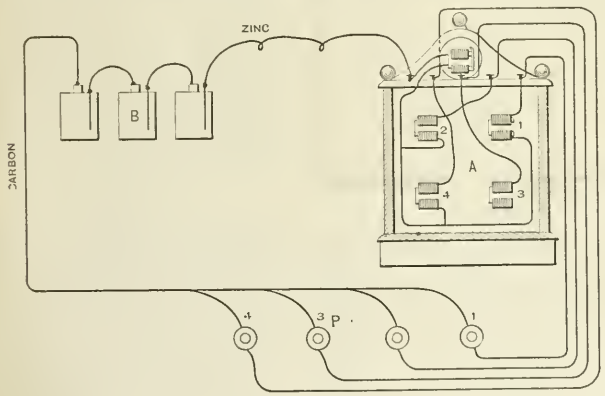
PLUMBING AND GAS FITTING.

Electric Bell Work.

BY OLIVER TWIST.

There are, doubtless, a large number of plumbers and tinners in country towns who do a little electrical work occasionally, and a larger number would probably be glad to do a little if they only knew how.

Let us suppose that Mr. Robinson has built a nice house, and, wishing to purchase a door bell, has called in your hardware store. You can then explain to him that you can fit up in his residence an electric bell that has advantages not found in any other kind. The bell may be placed in the kitchen or in any other part of the house and rung from a neat little "push" on the front door, which is much nicer than a gong fastened directly upon the door, which makes noise enough in the street to attract the attention of all your



Electric Bell Work.

neighbors. Well! That is what Mr. Robinson wants, and he gives you an order for one. If you put it in satisfactorily, the Smiths and the Joneses will want one also, and thus the tinner or plumber may fill in a "slack" time when he might otherwise be looking for a job.

Now, to help you a little more I have made a sketch, which by the aid of a little study will enable you, not only to connect up a single bell, but any number of pushes with a bell.

In order to distinguish from what part of the building the call comes we must have an indicator, or annunciator, as it is called. They are very useful in a private house or hotel, and a four-indicator annunciator, as we show here, may be placed in a kitchen and connected with the front door, dining room, parlor or chamber or any other places desired.

B represents the battery, which is made up in this case of three Leclanche cells, commonly known as the sal ammoniac or telephone battery—(two are generally enough for this size of annunciator, however)—connected up in "series," as it is called—that is, you must connect the carbon pole of one cell with the zinc pole of the next, and so on. You will notice that there are five binding posts on the top of the annunciator, one for each of the four numbers or names and one marked Z. A is a rear view of the annunciator showing how the magnets are connected, which operate the shutters or needles in front. These will be already connected when you purchase it, but it is just as well to know how they operate.

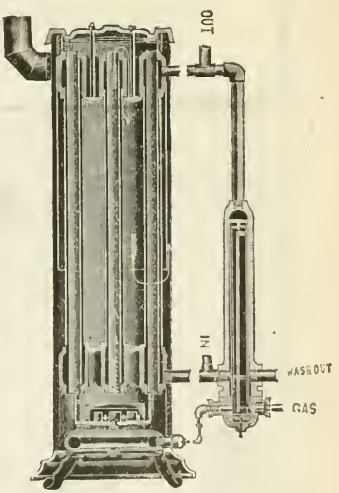
You can first locate the pushes where you desire them. Then run one wire from each push direct to the corresponding number or name on the annunciator, without connecting with any other wires on the way there. Now take a wire from the carbon pole of the battery to the pushes. This wire may be "branched" or "tapped," as shown in the sketch, as may be found most convenient for the connections. If you now take a wire from the pole marked Z to the zinc pole of the battery direct your "wiring" will be complete. You will find directions on the battery how to set it up, so that it is needless to repeat them here. A few remarks may not be out of place, however. Do not put two wires underneath one staple. Do not twist two or more wires together. Either of these may cause contact between the wires and complete the circuit, which would cause the bell to ring continuously or run down the battery.

Laying Earthen Pipe.

From R. J. M., *Trenton, N. J.*—In *The Metal Worker* of May 6, in relation to the laying of earthen drains, you very properly attach importance to the necessity of clearing out the earthen pipe thoroughly before connecting the iron house drain therewith. A very simple and practical method of accomplishing this result was adopted in laying earthen pipe in Princeton College about ten years ago, with which your correspondent, "W. J." is evidently not familiar, but which may interest him and other readers of your valuable paper. It was as follows: A rubber gasket of the full bore of the earthen pipe was inclosed between two circular boards, smaller than the pipe. This was placed in the first length of pipe laid and a stout cord attached which was carried through every length until the whole was laid. The cord was then pulled through the entire drain and the rubber gasket attached cleaned out every vestige of cement which might have remained. The pipe used in the work was without hubs, a collar being used to cover each joint where the ends of the pipe came together. If "W. J." is charged with the supervision of the laying of the earthen pipe he should see to it that the cement used in making the joints is wetted only in small quantities for immediate use, and if left unused for an interval of half an hour it should be discarded, as tempering will not make it available after a partial "setting." In applying the cement, the ends of the pipe and the hubs should be wetted, particularly in warm weather, when the porous pipe has a tendency to absorb the moisture in the cement.

Hot-Water Stove for Gas Fuel.

The accompanying illustration shows a sectional view of a hot-water stove for gas fuel put on the market by E. C. Merrill, 168 Second avenue, Pittsburgh, Pa. The arrows show the course of the burnt gases on their way to the flue, the idea in its construction being to return the products of combustion to the colder water before passing to the chimney. It is



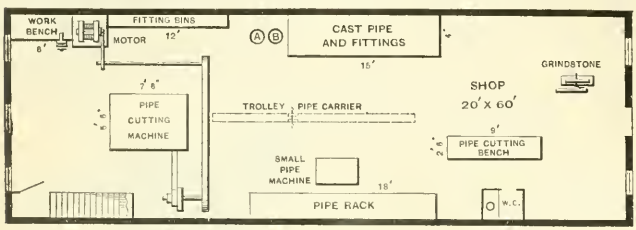
Hot-Water Stove for Gas Fuel.

claimed by this means that the water is taken from the heater at a greater temperature than that of the chimney or of the waste gases. The supply of gas is under automatic control, the temperature of water increasing the flow of gas to maintain the set degree. This thermostat is the property of the Thermovalve Company, and is, we understand, being applied to water backs of gas stoves and also of coal stoves, using gas fuel with satisfactory results. The thermostats are said to govern any kind of gas, and are not affected by the ordinary range of pressures, such as is met with in domestic fuel supply. It depends for its action on the expansive force of a $1\frac{1}{2}$-inch brass tube 18 inches long, and is so arranged that the water is brought into direct contact with the expanding metal. Another feature to which particular attention is directed is the absence of stuffing or packing boxes. The valves are tested for proper working

and also with hydraulic pressure to insure against leakage. It is said to be so simple that it can be applied by any intelligent plumber. The hot-water stove illustrated can, we understand, be used with either natural or coal or fuel gas for supplying bath and laundry water, its capacity being 1 gallon of hot water per minute, consuming a minimum amount of gas in maintaining the temperature of water when it is once heated. It is attached to the ordinary range boiler by means of the circulating-pipe connection.

A Modern Plumbing Establishment.

With some men a long business experience means an accumulation of cobwebs and junk, but with J. Toumey & Son, 132 East Forty-Second street, New York, a plan of whose shop and plant is shown and described, thirty years of business life means that to succeed against competition is to surpass it by intelligent enterprise. While only a plan of the working plant in a well-lighted basement is given, the business plant on the street floor meets all of the requirements of a modern and critically exacting trade. It is on this floor, with its large show windows, inclosed counting room, private office, telephone and drafting room, in addition to a salesroom admirably adapted to the purpose that a yearly business of a quarter of a million is transacted.



A Modern Plumbing Establishment.

The shop in the basement, however, is the center of interest to the trade, and is shown by the plan to be well arranged. It is well lighted by two windows and large glass double doors at the foot of the stairs at the front in Forty-second street, and by two large windows at the rear. It is entered from the office floor by stairs at the rear end. In the center of the shop at the rear, as indicated in the engraving, is a pipe cutting and threading machine of more than usual interest, made by D. Saunder's sons of Yonkers, N. Y. This machine was to have been a part of Messrs. Saunders' exhibit at the World's Fair, and was being slowly and carefully completed as the first of the kind ever made when the urgent necessities of their customer induced its earlier completion and the erection of another for exhibition purposes. It is known as the latest improved No. 6 pipe threading and cutting machine for power, and, with the special attachments ordered in this case, weighs 6000 pounds. It works pipe from 8 inches in diameter down to 2-inch, though the regular No. 6 works nothing smaller than 2½-inch pipe.

A universal gripping chuck of ample strength holds the pipe securely in place. The head is so arranged that the cutting off tool is always out of the way, yet ready for instant use. An arm is attached to the head to receive reamers, which not only remove the burr from the end of the pipe, but slightly bevel the inside edge, the arm being dropped out of the way when the operation is completed. The die frame is fastened to the head by massive hinges, and when the die is inserted the frame swings into place and is securely locked by a strong steel bolt. The head slides on the bed by the aid of a feed gear till the die takes hold of the pipe. By special arrangement an oil tank lubricates the different tools when in use, and the oil which drips from the work runs to a pocket at the back of the machine, from which it is pumped back to the tank when the machine is running. The Standard adjustable expanding die, for which many advantages are claimed, can be opened instantly when the thread is cut, and the pipe removed without reversing the machine. The thread-cutting chasers are removable, and are said to be of excellent quality and workmanship, and they can be sharpened by grinding, or duplicated if necessary.

Governing the speed to suit different sizes of pipe and the arrangement of gearing to secure power without the use of large pulleys, are other excellent features.

This machine possesses several attachments to which special attention is directed.

A chain hoist suspended from a trolley running on an I-beam fastened to the ceiling in line with the centers of the machine is arranged to lift large pipe and carry it to the machine, and to support one end in a carrier if necessary while it is being worked.

Not less interesting to the readers of *The Metal Worker* who could with benefit run by power many of the tools they use, is the electric motor which drives all of the machines It is a 3 horse-power Edison of the C. & C. style. It sits against the wall at the end of the work bench at the rear, occupying a space 3 feet square. Motors of this power vary in cost with make and quality from $300 to $500, and seem to possess peculiar advantages for shops where a limited and intermittent power is desirable, as they use no coal, make no ashes, and require no engineer, which together might make an expense of $3 to $5 per day. Electricity is supplied continually and the quantity required in Messrs. Toumey's shop for the motor described is furnished at 50 cents per day. The operation and management of a motor is so simple that it can be used by the apprentice safely and satisfactorily, the current being turned on by a handle placed on a small circular brass disk, from a horizontal to a vertical position. The current is then gradually applied to the motor by a lever on a graduated switchboard and the power is transmitted by a belt from the motor to the main shaft. To work the two levers mentioned is all that is required to operate the motor. Belts run from pulleys on the main shaft to the different machines. One of Saunder's No. 2 1XL pipe machines is used on pipe from 2½-inch down to the smallest sizes and is conveniently located.

Along the wall by the motor is arranged the fitting bins, next is a portable forge, then the heating stove and then large racks for cast iron soil pipe and fittings. On the opposite wall is a rack for wrought iron pipe. An ordinary pipe fitter's bench and the ever useful grindstone are conveniently located. In addition to the power pipe working machinery, a full set of hand tools and machines for working all sizes of pipe up to 6-inch is a part of the portable outfit. Such excellent facilities enable them to make a specialty of the screw joint iron pipe system of house drainage and of pipe cut to sketch.

Messrs. Toumey are to be congratulated on having so early appreciated the advantages of new and advanced appliances and adapted them for the benefit of their trade. Their plant, with the electric motor, was put in operation in July of 1892 and has been busily occupied since.

Pouring Hot Lead Into Wet Hubs.

From F. P., *Jackson, Miss.*—A singular accident recently happened to one of my men who was engaged in laying a cast iron house drain in a cellar where there was a considerable quantity of water. He was in the act of pouring some of the hot lead into the hub when the whole thing exploded and the lead was scattered in all directions, he, however, escaping with only some trifling burns. I am told that such is not an unusual occurrence where hot metal is poured into a hub where there is some moisture. Can you suggest anything to lessen the danger in a locality where wet cellars are the rule instead of the exception.

Answer.—Inquiry among the trade confirms the possibility of accidents such as our correspondent refers to occuring, in which men are exposed to considerable danger. The experience which sufferers who have placed themselves on record have had, is that as soon as the hot metal is poured into a hub where the slightest moisture exists, an explosion is certain to follow. The safeguard against such danger is, it appears, after the oakum is well calked in, no matter whether it is water saturated, or otherwise, to place a piece of tallow or other fat in the hub, which expedient, we are informed, effectually removes all danger of explosion.

Peck Bros. & Co.,

manufacturers of plumbing and sanitary work, New Haven, Conn., and 47 Cliff street, New York, have a new catalogue of their goods just from the press, which will be known as the Architects' Edition. Later another volume will be issued, designed for plumbers' use. While in the main both editions will be similar, in each will be found many hints and suggestions and much information useful to both classes. The book before us is handsomely printed, in both black and color, on fine, heavy plate paper. It contains 328 pages, 11⅝ x 9¼ inches, substantially bound in leather. The work shows much care in preparation, and the compiler, W. E. Hinsdale, is deserving of great praise for the ability displayed in its production, his efforts evidently having been ably seconded by the firm in meeting the necessarily large expense. The engravings are many in number—at least one to a page—and are of a high grade, showing evidence of being prepared expressly for this book. On four of the pages in front are given illustrations of the mills and offices at New Haven, which are said to afford a floor space of over 3 acres, the New York sales and show rooms and their Chicago branch. To facilitate the identification of articles to which reference may be made, every illustration to and including page 303 has been numbered from 1 to 450 consecutively. From page 304 to the end has been devoted to illustrations and information which will be of value to architects in making up specifications, giving sectional views, &c., of a varied line of goods, with explanations in detail. The cuts illustrate simply parts, and apply only to classes of work where the larger and more expensive fixtures in the preceding pages would not be wanted. The line of lavatories illustrated at the beginning of the book should afford an assortment to choose from capable of satisfying the most fastidious tastes. Then are given drinking fountains

and an almost endless variety of basin cocks. In appropriate places of the book are presented a large number of *fac-simile* illustrations in color, showing decorated basins and closets, so that one may get the effect of the numerous designs, tints and colors where it is not practicable to see the goods themselves. Attention is later given to bathtubs and many forms of bathing apparatus and attachments.

Country Sewerage.

From E. & A., *Pulaski, Tenn.*—Please give us your opinion of a cesspool properly constructed and ventilated up to the prescribed regulations of sanitary boards. Are they not strictly sanitary, and are they not the next best thing to sewerage? Are they not adopted by some city sanitary boards? We are in a kind of controversy here with some of our resident physicians. Our board of health approves of them, but they are opposed by outsiders.

Answer.—The cesspool question is one which is not easy of solution, because of the difficulty of dispensing with cesspools on the one hand and of their construction and care where they are a necessity on the other. Our correspondent does not state the circumstances under which his local board of health approves of the use of cesspools—whether as receptacles for the waste matters of individual houses—that is, a cesspool for each house—or a cesspool to be used as a receiving vault for the sewage of a whole town or village. We will assume, however, that he has in view the construction of a cesspool for each house. The cesspool should be constructed in such a manner as to be absolutely water tight—not of the "leaching" variety which allows the soakage of the liquid sewage into the earth. The walls and bottom should be made of brick or stone, laid in cement and well coated over with cement, or, better still, a layer of coal tar. We do not know what the "prescribed regulations of sanitary boards" may be in different places, but it appears to us that the one great requisite is that it be water tight. The cesspool of this character is permitted in unsewered portions of this city, where its construction is subject to the inspection and approval of the Board of Health. Under the Brooklyn health regulations the same rules as above are in force, and in addition the location, unless under special permit, must not be nearer than 20 feet of a dwelling. In Philadelphia the construction of cesspools is forbidden where a sewer is available. From the above it will be seen that the cesspool is not considered an "unmixed blessing," and we do not, therefore, undertake to answer our correspondent's question as to the "strictly sanitary" character of what must be always considered, at best, as but a make-shift to be adopted only where a sewerage system is not available. In those cities where they are permitted, the most exacting restrictions are placed on their care and the disposal of their contents. There is also to be considered the necessity of ventilation of cesspools, regarding which our correspondent makes inquiry, but for which the sanitary codes of the various cities where they exist make no provision. Among recommendations given the following are samples: One, recommended by the secretary of the New Jersey State Board of Health, is to have a series of pipes entering at various points below the top or cover of the cesspool and terminating in the center in an upright tube extending above the ground. Another is the erection of a wooden flue 10 feet square, set above an opening in the top of the cesspool, the foul air in its upward passage passing through various layers of charcoal. This ventilation, however, not being called for where the cesspool is tolerated, is a question that may be settled by each house owner according to the circumstances which may govern his particular case.

Washington Gas Fitting Regulations.

In *The Metal Worker* of April 29 we reviewed the new plumbing regulations which recently went into force at the National Capitol. We print below extracts from the regulations governing the practice of gas fitting in the District of Columbia, which became operative at the same time:

SEC. IX. Upon the completion of any system of gas piping in a building, and before the floors are laid or the pipes and fittings concealed, there shall be filed in the office of the inspector of plumbing, by the plumber doing the work, a detailed plan of the same, showing the location and size of each pipe, with a statement that the system is ready for inspection.

SEC. X. Upon the filing of the plan described in section IX, the inspector of plumbing shall promptly cause the system to be inspected, and tested with a pressure of not less than six inches upon a mercury gauge.

If the test and inspection be satisfactory a certificate of approval shall be issued by the inspector of plumbing.

No meter shall be attached to any pipe or system of pipes previous to the issuance of such certificate.

SEC. XI.—The sizes of pipe used shall not be less, nor the lengths greater, to the number of burners stated, than those specified in the following table:

Size of pipe. Inches.	Greatest length allowed. Feet.	Greatest number of burners.
⅜	6	1
½	20	6
¾	40	20
1	60	35
1¼	80	60
1½	150	100
2	200	200
2½	300	300
3	450	450
4	600	750

Smaller pipe than ½-inch shall not be used for ceiling outlets, except for lighting halls, pantries, washrooms, bathrooms and kitchens.

SEC. XII.—The pipe used shall be the best quality of wrought-iron pipe, with galvanized-iron fittings, and joints shall be made with white lead.

All pipes shall be suitably supported and stayed with pipe hooks, straps and screws.

All pipes shall be properly graded.

All split pipes must be removed.

SEC. XIII. All main risers shall be run in an inside partition.

SEC. XIV. Each gas meter shall be located in accordance with directions given by the inspector of plumbing.

All meters located in cellars must be set at least four feet above the cellar floor.

SEC. XV. The service pipe shall be run, and both connections with the meter shall be made, by the gas company.

SEC. XVI. No extension or alteration of any existing system of gas piping in a building shall be made without the inspection and approval of the inspector of plumbing.

SEC. XVII. Upon the completion of the building in which a system of gas piping is run, and the hanging of the gas fixtures, an application for a final test and approval of the entire system shall be made, to be followed by the final inspection and approval.

Plumbing Exhibitors.

From the official catalogue of the World's Columbian Exposition we take the following list of exhibitors of plumbing and sanitary materials:

Alberene Stove Company, New York.
Dawes & Myler, New Brighton, Pa.
Day Mfg. Company, Detroit.
Instantaneous Water-Heating Company, Chicago.
Kelly, Thomas, & Bros., Chicago.
Kilbourne & Jacob Mfg. Company, Columbus, Ohio.
Lang, E. M., & Co., Portland, Maine.
Lehner, Johnson, Hoyer Mfg. Company, Chicago.
McCambridge & Co., Philadelphia.
Mosely Folding Bath Tub Company, Chicago.
Norton Brothers, Chicago.
Oswego Indurated Fibre Company, Oswego, N. Y.
Peck Bros. & Co., Chicago.
Randolph & Clowes, Waterbury, Conn.
Smith & Anthony Stove Company, Boston.
Standard Mfg. Company, Pittsburgh, Pa.
Steel Clad Bath Tub Company, Detroit, Mich.
Stewart Ceramic Company, New York.
Strong, Boyce & Co., Indianapolis, Ind.

The Chicago Master Plumbers.

The Chicago Master Plumbers' Association held the first meeting in their new quarters at 197 East Madison street, Monday evening, May 8. The rooms have been handsomely decorated, many pictures adorning the walls, and the floor is covered with a fine carpet. At this place will be located the large library owned by the association; also the office of Secretary Alex. W. Murray. The officers of the association for the year 1893 are as follows: T. P. Culloton, president; P. M. Murphy, first vice-president; J. Barrett, second vice-president; J. Connell, third vice-president; W. T. Geary, fourth vice-president; C. Byrne, fifth vice-president; J. J. Rourke, sergeant-at-arms; P. Sanders, treasurer; Alex. W. Murray, financial and recording secretary. The board of directors consists of David Whiteford, G. A. Larson and M. Mandable.

The principal business of the evening was the election of delegates and alternates to attend the eleventh annual convention of the National Association of Master Plumbers, which will meet in Lincoln Hall, Milwaukee, Wis., Tuesday, June 13. The judges of election were Paul Redieske, Alex. F. Irons and Daniel J. Rock. The following delegates were elected: Daniel J. Rock, Alex. W. Murray, P. Sanders, J. J. Wade, M. J. Corboy, Alex. F. Irons, E. Baggot, J. J. Rourke, J. B. Breen, A. C. Hickey, M. Ryan, H. A. Blac[illegible], Wm. T. Geary, M. A. Mandable, J. G. Webber, C. J. Herbert, David Whiteford, T. C. Boyd and P. M. Murphy. Robert Griffith and Andrew Young are delegates by virtue of their being ex-presidents of the National Association. T. P. Culloton is also delegate as president of the local association. The alternates elected were as follows: C. C. Breyer, G. A. Fehr, J. R. Alcock, Paul Redieske, Chas. Byrne, J. Harden, P. J. Morrisey, M. L. Morris, J. T. Dalton, A. Watt, D. Wilson, Wm. Ryan, J. Barrett, W. Gay, J. Connell, J. H. De Veney, James H. Roach and T. Hanly. The competitors in the prize essay contest will read their essays at the next regular meeting, May 22, and the author

receiving the greatest number of favorable votes will be awarded the prize of $25.

TRAPS AND VENTS.

C. H. SCHRACK, 32 Carmine street, New York, finds a good demand for his plumbers' charcoal furnace, which is made heavy to stand rough usage, and fitting tight in all its parts, a fire can be held a number of hours. Another of his inventions is a patent sink strainer which can be put in a sink in five minutes, and can be used in connection with any sink. The device consists of a cross bar which fastens to the sink in the same manner as the ordinary strainer. The strainer fits over the cross bar and is held by a brass bolt screwing into a brass nut, so that corrosion will not prevent its being unscrewed.

THE NEW YORK GAS FIXTURE COMPANY, who recently moved their office to the factory building at 478 and 480 Pearl street, New York, have now a fine display of both gas and electric light fixtures and combination fixtures in their showrooms. The showrooms are divided, giving an elegant effect to their different manufactures. Wiring for 40 electric lights in the building has just been completed by Mead & Tichenor of 10 Whitehall street, New York.

A. A. HUNT of the Trimont Mfg. Company of Roxbury, Mass., has been visiting the trade in New York City in the interest of various Trimo pipe wrenches.

AT 153 FRANKLIN STREET, NEW YORK, John Regan has his office and showroom, where he exhibits a fine lot of gas fixtures and lavatories, water closets and plumbing fixtures of the latest design. Here is also his sheet-iron, tin and roofing shop, while at 911 Franklin street he has his pipe shop, where steam power drives machinery capable of working pipe up to 12 inches. He has recently installed the pipe work for a refrigerating plant for the Jersey City Packing Company, and is working on contracts for the plumbing work at the Seventy-first Regiment Armory, the Snake Hill Insane Asylum and the public school at Eighty-fifth street and Madison avenue.

E. B. LEONARD is just getting settled in new quarters at 14 Lombard street, Newark, N. J., where the plumbing, gas, steam and hot-water fitting department of his business has ample accommodation. To reach his office, which is located here and is of modern arrangement, it is necessary to pass through what is virtually a glass show window extending entirely across the front of the building, the entrance being in the center. This is used to display a fine collection of the latest plumbing fixtures set up as if for actual use. At 78 Boyden street Mr. Leonard conducts his stove and furnace business and at Fourth and Belleville avenues a large well-lighted shop is devoted to the tinning business.

THE FOLLOWING DELEGATES, being master plumbers of Pittsburgh and Allegheny, Pa., have been elected to attend the eleventh annual convention of the National Association of Master Plumbers, which meets in Milwaukee, Wis., from June 13 to 15: J. P. Reineke, R. J. Bradshaw, George Sands, F. J. Gray, J. O. McGinniss, J. L. McShane, J. J. Kennedy, James Hay, John Cowling and C. H. Humbert.

B. M. MARTIN, 83 South Fifth avenue, New York, makes a specialty of brewers' brass work, running his own foundry and finishing shop. His facilities enable him to do difficult job work in a satisfactory manner.

O'BRIEN & RYDER, 154 Spring street, New York, make their showroom do them excellent service by a fine display of modern plumbing fixtures. On one side a white marble platform supports several styles of water closets of different decoration and finish. Then comes a handsome lavatory in white marble and a set of urinal stalls of the same material. On the opposite side are arranged a set of earthenware laundry tubs and the office fixtures, so that, without the effect of crowding, their goods present a fine appearance.

E. ASPINALL, 98–100 Beekman street, New York City, sole agent for Twyford's English earthenware for plumbers' use, refers to what he says is the largest lavatory slab and basin made, or anywhere to be found. This particular size is on exhibition at his place of business, and the oval bowl measures 24 x 17 inches. These are also made in a variety of shapes and designs smaller in size, for numerous uses. The combined Athena lavatories, from the same pottery, present a pleasing appearance. They are cased in iron castings of a fine degree of workmanship and decorated in various colors to represent different hard woods, with beveled plate mirrors above and ornamental brackets or legs for support. The excellence of design and execution is what he emphasizes. The lavatories are supplied with fittings made in this country by Peck Bros. & Co.

E. BAGGOT, 169 and 171 Adams street, Chicago, has large contracts for plumbing, drainage, gas and electric fixtures. At present there are over five hundred men in his employ. Among the jobs on hand and being finished can be mentioned the following: At World's Fair, 57 restaurants and large kitchen for Wellington Catering Company; Virginia, Idaho and Chinese Buildings, Irish Village and Hagenbeck's Arena, Windermere Hotel, Fifty-sixth street and Cornell avenue; power house for Marshall Field's Building, Wabash avenue; Barry Bros.' Hotel; Lakota Hotel, Michigan avenue and Thirty-third street; John Quincy Adams Building, 242–246 Adams street; and Humboldt Park Refectory, Humboldt Park.

FROM HEPE, KOVEN & CO., 18 Spruce street, New York, is received a catalogue in a crimson cloth cover bearing their name and address and a cut of a circulating range boiler in silver. From the text on enameled paper in a dark shaded ink it is learned that they make a specialty of manufacturing high pressure circulating range boilers for the larger trade who distribute their goods. These boilers have a special head and bottom to secure strength and prevent leaks and are made both horizontal and upright with connections so placed as to meet local requirements. They are furnished with either a copper or iron coil on the inside, in addition to the regular connections, so that they can be connected with a steam plant and the water heated by steam. Boilers up to 1000 gallons are furnished. Expansion tanks for hot-water heating plants, air receivers used with beer apparatus and calcium light cylinders. Tanks for storing oil and water tanks for house supply either round or rectangular are made up to 10,000 gallons. The last two pages show how to connect a boiler with a water back, and a view of their plant at Jersey City, N. J. In addition to their boiler business they furnish steel plate radiating sections for hot-air furnaces.

Electric Machine Tools.

At the new works of the Crocker-Wheeler Electric Company at Ampere, East Orange, N. J., all the power is supplied by electric motors. The peculiar feature of the equipment is that, with the exception of a few short lines of shafting placed to operate small machines requiring only an insignificant amount of power, all of the larger machines are run by motors mounted upon their own frames. The electrically driven machines include planers, blowers, multiple and single spindle drills, sheet-metal shears, shapers, lathes, presses, pipe threading machines, &c. With only two or three exceptions, it was not found necessary to change in any way the form of the machine drivea. In most machines there is some place on the frame where the motor can be placed.

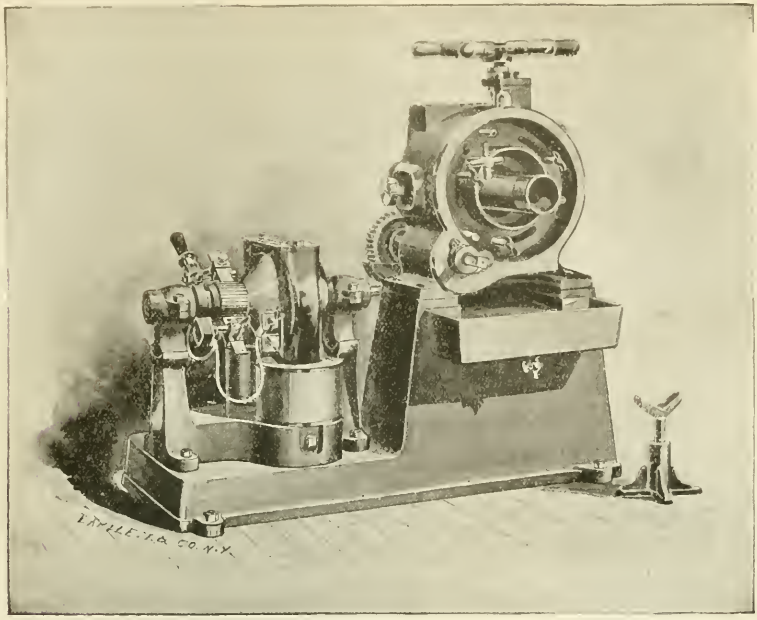
From an article on this subject by S. S. Wheeler of the Crocker-Wheeler Company, in a recent number of the *Electrical Engineer*, we take the following:

I have concentrated no little time and money on the many different problems of so adapting or modifying electric motors that they may be built directly into such tools as lend themselves to the purpose, in place of belting the motors to the countershafting here and there. Some tools invite this treatment much more than others do, and in the future I believe that the tools of newer design will owe their specific shape and construction very largely to the changes now being introduced by the use of electric power in this direct maaner. This important class of improvement is immediately suggested by the appearance of the temporary rigs, in a shop using electric power, but, like many other things, it had not been given attention by most persons until the use of electricity for power had become pretty general After adopting a line of electric bars or mains through a shop in place of the ordinary revolving shafting, and after belting a few motors to lathes and other tools and connecting them to the bars, it is easily seen that much better mechanical arrangements could be made by building in the motors as an integral part of the several tools. This construction gives rise to directly connected machine tools, a new line of machinery destined, in my judgment, to be of very great importance. The machines employed at the Crocker-Wheeler works are the regular standard tools of the market, but with motors combined, both being properly proportioned for their purposes, so that when the small flexible cable or lamp cord is connected to them from the power line they become operative and are self propelling tools, readily portable if desired. Machinery of this kind obviously has a number of important advantages. It requires no setting up. It can be moved and then used so readily that it makes temporary shifting of machinery to meet requirements of extra work in one department practicable. A single tool can be run at any time without running others, thus saving all shafting friction, &c. The tool having no belts, and the power being generated in the head stock just where it is consumed, the machine runs much more quietly, &c.

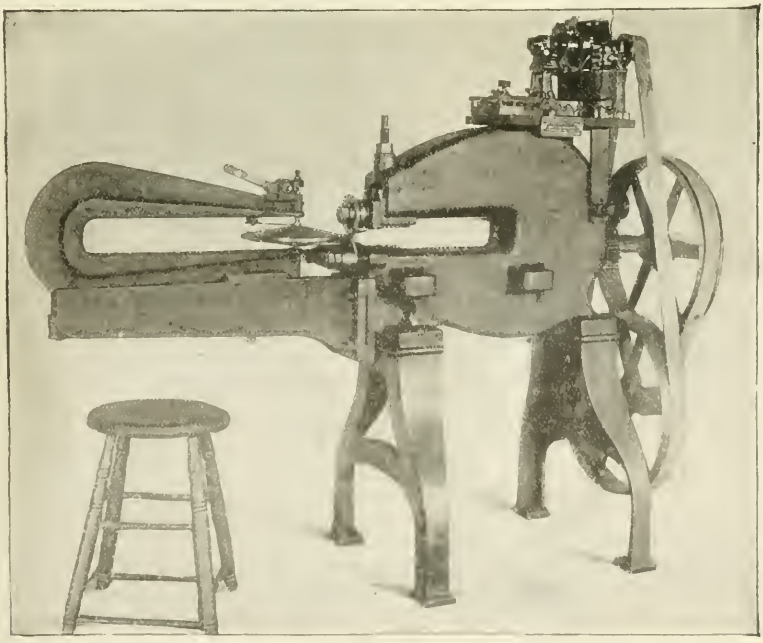
Quite a variety of direct connected machines have already been built and put in use with such success that we now propose and are prepared to design motors for all classes of machine tools. A brief description will, I think, be found of general interest. The electric lathes, for example, are built on this principle, the motor armature taking the place of the belt pulley and the field magnet frame being part of the lathe bed, securing simplicity and rigidity. . . . . .

I am glad to be able to show also another very interesting direct application, namely, the operation of sheet metal power shears. The ¾ horse-power motor while attached directly to the tool is geared up by belting, passing over intermediate pulleys, which at the same time serve as belt tighteners by being adjustable vertically. The power required for the work is much reduced by the directness of application. The machine can be stopped and started in an instant by the switch knob near the motor, and can be moved to any part of the shop and used at once without the troubles incident to lining up.

In shops already provided with a number of tools driven by belting, and where it is found desirable to introduce electric power, the motors are simply bracketed to the ordinary form of tools, and same as with all machines of this character. In connection with these direct driven tools it may be well for me to call attention to the absolute practical results which have already been obtained by the use of machines intermittently operated, only 15 to 25 per cent. of the total power supplied by the engines is expended in useful work. It is well known that a very large portion is required simply to move the



ELECTRICALLY DRIVEN PIPE-THREADING MACHINE.



ELECTRICALLY DRIVEN SHEET-METAL POWER SHEARS.

connected by means of belting. . . . Still another variety of application is shown in the electric pipe threading machine, which needs no special description, as its operation is precisely the e'ectricity in machine shops, than which no subject can be of greater interest to manufacturers.

Under the usual manufacturing conditions involving the driving of tools or great pulleys, belting and shafting, which starting from the engine room, convey the power from floor to floor, and distribute it to the different wings and parts of the factory.

STEAM AND HOT WATER.

The Master Fitters' Convention.

In preparing for the coming fifth annual convention of the Master Steam and Hot-Water Fitters' Association of the United States a circular letter of invitation has been addressed to the trade, signed by President P. S. Hudson, Secretary George H. Reynolds, 628 Rialto Building, Chicago, Ill., and the Executive Committee, consisting of L. H. Prentice, C. H. Simmons, John Davis, F. W. Lamb and H. A. Kroeschell. The following is the text of the circular letter:

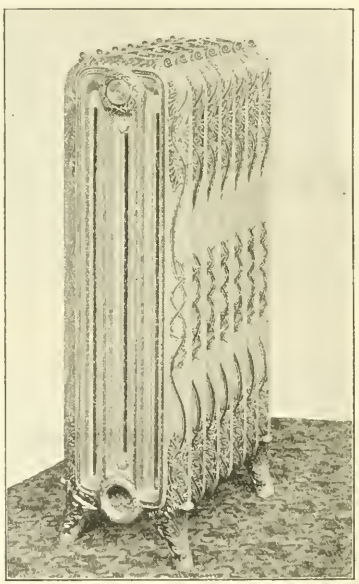
The fifth annual convention of the Master Steam and Hot-Water Fitters' Association of the United States will be held at the Revere House, in Chicago, commencing Tuesday, June 6, at 10 o'clock a.m. A cordial invitation is extended to all contracting master fitters to attend this meeting, whether members or not. We urge each and every one who receives this paper to make inquiry of others of the craft, and to advise any whom this has failed to reach that they are included in the invitation. The reading of papers by members, which was introduced at our last convention, was an attractive feature, and they were appreciated. We purpose continuing this at the coming convention, and hope they will prove of still greater interest. Certainly, every master fitter in the United States who intends to keep abreast of all that is modern and new, and tends toward progress, will visit the World's Fair, for there will be exhibited the concentrated experiences of the world. The representative villages, displaying the home life of nearly all nations, should alone be of sufficient interest to pay for the journey. Then why not make the trip so as to be here on the dates of our convention, and, after adjournment, profit by all these interesting studies that can be offered not more than once in a lifetime? The Revere House, which is located on the corner of North Clark and Michigan streets, has wholesome and ample accommodations for all. For rates see inclosed postal card, which please fill out and mail to us. Those desiring to make exhibits of their goods at the convention can secure information and particulars by addressing the proprietors of the Revere House. World's Fair transportation rates are all that the railroads will consider, which, it is hoped, will be full better than those usually granted to people attending conventions.

Accompanying the notice are postal cards, on which application may be made for rooms at the Revere House; also credential certificates for members and proxies. There is likewise distributed a pamphlet containing a list of the members of the Association.

It is to be hoped that this convention, to be held next month in Chicago, will be generously attended, and there is every reason to believe that such will be the case. It is needless to dwell upon the attractions that Chicago offers this year, and the members who attend the convention will, without doubt, be royally treated by their Chicago brethren. In addition to the interest that the convention always excites, there will, of course, be the added attraction of the fair; and, as all of the master fitters throughout the country who can possibly do so will undoubtedly visit the fair, it will be an excellent plan to time their visit to coincide with this convention, so that they may be present at its deliberations, and, if not already members, will have an opportunity to look into the association with a view to becoming members.

New Four-Column National Radiator.

The American Radiator Company, general offices at 111-113 Lake street, Chicago, have added to their extensive line the new four column National direct-water radiator, illustrated herewith. The standard hight, 38 inches, contains 8 square feet of surface to the loop, and, we are informed, requires, proportionately, a less amount of water than any other style or make of direct-water radiator. The four-column National is especially designed to fill the demand for a radiator of large surface to fit limited spaces. It is handsomely decorated, as is shown in the cut.



New Four-Column National Radiator.

The Harrisburg Boiler & Mfg. Company of Harrisburg, Pa., are about shipping three of their boilers to Havana, Cuba, to fill orders taken for them at that place. R. D. Droop of Havana has been appointed the company's agent for Cuba.

The Efficiency of Heating Apparatus.

We are permitted to print from advance pages of a catalogue about to be issued by Hopson & Chapin Mfg. Company, New London, Conn., the following observations on the efficiency of heating apparatus. It is gratifying to find in a trade publication of the catalogue sort a discussion of principles quite free from extraordinary praise of the manufacturer's own heater, but we believe that this unusual style will commend itself to the thinking members of the trade. We quote from the concluding pages of the catalogue as follows:

The foregoing illustrations and descriptions exhibit apparatus for warming, and for warming and ventilating. The most important question connected with the subject is their proper installation in any premises. Allusion has been made in preceding pages to the importance of a carefully and intelligently estimated layout and a proper plan of erection. After an active experience of several years in the warming and ventilation of every variety of buildings we are prepared to say that the plan under which any heating apparatus is erected is of the first importance and all other questions connected therewith should follow it. We know very well the reverse method of arriving at a decision is frequently taken. The subject is often approached in the view that some heating apparatus, as it is manufactured, constitutes a machine, measured in feet or

gallons, that is of itself competent or not to satisfactorily warm a given premises. A boiler is often held to be pre-eminently fit to receive the praise or blame of the entire plant, including the merit in the use of water to carry heat. It must be plain, however, to any one on reflection that a farmer's kettle, inclosed, will warm any premises if it is large enough, and that the best planned boiler, specially built for hot-water heating will fail to do so if the other links of the chain fail.

Now, there are points of great importance to govern the selection of a boiler. They are, efficiency per pound of fuel consumed; labor and skill required to maintain a desired temperature; facility for cleaning, and durability of joints and parts. These points constitute a large field for selection, and a close examination of construction and records of years' use would disclose a wide variety of results. The point we wish to make is that the legitimate ground for choice in boilers is limited to nearly the above points.

In the matter of radiators, the heat units emitted by the different constructions, especially in different locations, is a question that receives less attention than it deserves. Care is taken over the size of radiators, but little given to their location. It is our experience that within certain limits the latter question is more important than the former.

Again, short rules intended to promote quick sales are in common use. The process is to divide cubic feet by a factor. The loss of heat from a warmed apartment to surrounding air of a lower temperature is through three exits, viz.: through glass, outside walls and by escaping warmed air. The loss of heat through glass can be accurately determined; that through walls may be determined with sufficient accuracy, but the quantity of air lost from any apartment cannot be accurately measured. It may be approximated by experience under similar conditions. The construction of buildings, their location and uses, the desires and needs of the occupants, the values of heating surfaces in boilers and of radiating and air heating surfaces in radiators, vary so greatly that no fixed rule for allotment is safe. The fact is, that a plan for the installation of a fit hot water plant, competent as to the allotment of capacities, suitably proportioned in its parts, and able to accomplish the desired results, is a work of engineering, computation, skill and experience, not of commercial push alone.

In this connection it must be borne in mind that the results from an intelligent equipment of hot-water heating apparatus may not be limited to the mere production of heat. Stoves, steam and furnaces produce heat, and in great abundance. If heat alone were the object sought but little thought need be given to plans. Modern cultivation has progressed beyond the mere desire to be warm. The apartment should be uniformly warmed at every point, not merely in the center or on warm walls, but on floors and about cold windows. The several rooms of a building should be uniformly temperate and the plant yield desired warmth without frequent regulation or attention, but be governed according to out-of-doors temperature by the fire. The intent of the apparatus is to sustain heat. The quantity of fuel in combustion, the rate of combustion, the temperature of water in use, its uniform delivery at different points and at various levels in the building to accomplish a uniform or uniformly graded result, are features to be realized.

In ventilation a sufficient quantity of air of an agreeable initial, as well as resultant temperature, free from impurities, its point of entry, the exit of vitiated air, the velocity of both currents, that of the incoming air at a rate less than a perceptible current, and of the outgoing air at a velocity sufficient to insure both the heat and ventilation desired, are, or may be, demands of modern intelligence.

Cellar Drain Connection.

From F. P., *East Fairfield, Vt.*—I was much interested in the plumbing department of *The Metal Worker* of February 25, and would still further draw on your store of information by asking if the inclosed sketch shows the proper way to connect cellar drain with house drain? Would it be necessary to use trap No. 6 if a bell-trap cesspool was used?

Answer.—The sketch sent by our correspondent simply shows a trap at the foot of the vertical soil pipe line—a fresh-air pipe above the trap aforesaid, taken out of vertical soil pipe, and a cellar drain with a bell-trap. The arrangement is defective, first, because there should be no trap at the foot of a vertical line of soi pipe. A careful study of the diagram showing a sectional view of house plumbing, which appeared in *The Metal Worker* of February 25, and to which our correspondent refers, will show how the connection of the soil pipe should be made with the house drain, viz., by means of a Y-branch and a one-eighth bend, and without any trap whatever beyond the main running trap on house drain inside front wall. The next defect shown in the sketch is in the use of a bell trap and cesspool in cellar floor. The bell trap was long ago discarded for indoor use, as from the nature of its construction it is neither cleanly nor secure. If a cellar floor must be connected with the house drain our correspondent is advised to use an ordinary running or S-trap, as shown in *The Metal Worker* of April 15, with the further security of a flap or tide-water valve to protect the cellar from sewage backing up in case of house drain obstruction.

HEATING NOTES.

The J. F. Pease Furnace Company of Syracuse, N. Y., have disposed of their retail and contracting business in the city of Boston and immediate vicinity to Albert B. Franklin, 228 Franklin street, in that city. Mr. Franklin will hereafter sell and erect in that district all heaters and furnaces made by the company, and has retained the services of some of the best men formerly employed by the Pease Furnace Company at 75 Union street. John Demarest will continue to manage the New England department of the company's business and will make his headquarters at 228 Franklin street. Mr. Demarest will have general charge of the wholesale business of the company and will give assistance to the trade in laying out adjustments, securing contracts, &c.

From the D. F. Morgan Boiler Company of New York and Chicago we receive a four-page sheet, showing four different views, in a handsomely executed half-tone engraving, of twenty-eight fine houses recently erected in East Orange, N. J., in which their steam boilers have been used.

The plant of Baker, Smith & Co., at South Fifth avenue and Houston street, New York, though a large one for heating and ventilating engineers, is often taxed severely to meet their requirements. The basement contains a 75 horse-power engine to drive their different machines, including several pipe-cutting and threading machines, a pipe-sawing machine and five blacksmith forges. The basement is also used for a receiving room for casting, besides affording ample storage for a varied stock of pipe. On the first floor is the shipping and receiving office and a very completely equipped machine shop. The second floor has the counting house, the private offices and large drafting rooms, besides a large stock of manufactured goods. The third floor has the carpenter shop and the pattern makers, and in a separate room is a large brass finishing shop, where many of the valves used in their work are finished. The fourth floor is the tin and sheet-iron shop, where some nice workmanship can be seen by a visitor at any time. The large force of workmen are under the superintendence of Augustus Pierce, who has systemized their labor so that the work is accomplished with a smoothness which seems almost like inaction. Some of the work now in hand is the residence of Cornelius Vanderbilt, which will have 113 coils for indirect hot-water heating, the Scott & Bowne building, the Blake building, the Manhattan Electric Light Company's building and the Havemeyer building, all to be heated by steam. The pipe work for the Cable Road power plant was also installed by them.

F. B. Cryer & Co. have just moved into a more commodious building at Newark, N. J., just opposite the Delaware, Lackawanna & Western Railroad station. They report activity in the Steam and Hot-Water heating line, and are bringing out some new things in Hangers and Plates.

Clarkson, Scott & Co., at 118 Custom House place, Philadelphia, are a new firm of engineers and contractors who will make a specialty of heating, ventilating, drying and pipe work. Mr. Clarkson was for years one of the engineering corps of Wilson Bros. & Co., architects and engineers at Philadelphia. Mr. Scott had a long experience with the Onderdonk Heating and Ventilating Company of the same city. The new firm start out with a contract for installing a steam-heating plant at the new county prison at Holmesburg, Pa., amounting to $67,000.

The Newark Heating, Ventilating and Machine Company, 22 Atlantic street, Newark, N. J., are busily engaged in preparing for the Ventilating Fan season, now at hand. Some new things in Fans that will probably be of interest are in course of completion.

President Joseph Bond of the American Radiator Company, Chicago, is making a few days' visit in New York looking after the interests of the company.

McMann & Taylor are a new house at 42 Cliff street, New York, manufacturing and dealing in wrought and cast iron pipe and boiler tubes, plumbers', steam and gas fitters' supplies of all kinds, and hand tools and machines. They make a specialty of pipe cutting to sketch with promptness and accuracy. H. W. McMann brings a 30 years' experience, being formerly of the house of T. R. McMann & Co., Geo. W. K. Taylor was with the Eaton, Cole & Burham Company for 20 years.

Joseph T. Robbins, Newton, Iowa, is the patentee of an improvement in water heaters for warming buildings. A feature of it is the location of the furnace whereby the fuel is supported above the tubes and the products of combustion lead downward and beneath the water reservoir.

From George B. Cobb & Co., 42 Duane street, New York City, contracting engineers for heating apparatus, we have received a set of illustrated catalogues issued by the American Boiler Company, and describing the various heaters which they now make. The catalogues, of oblong shape, are very neatly printed, illustrated with fine engravings and altogether are gotten up in an elaborate and attractive style. The series is bound in various

colors, giving a pleasing effect. One catalogue is devoted to the Florida steam heaters, with which apparatus the public has long been familiar. General and sectional views illustrate its construction thoroughly, and descriptive text is likewise given. The second circular relates to the Tropic hot-water heater. This apparatus, as explained in the preface, was formerly known as the Florida hot-water heater, but in order to avoid confusion with the steam boiler by that name it has been changed to the Tropic. The Spence hot-water heater is similarly illustrated and described in a separate pamphlet; likewise the Soleil safety steam heater, which was put on the market last year. Two other pamphlets in the series give attention to the widely known Perfect hot-water heaters and to the American safety sectional steam boiler, which was illustrated in *The Metal Worker* not long ago. The Modern portable steam boiler completes the list of catalogues.

A LARGE POSTER, resplendent in scarlet ink, is issued by Le Bosquet Brothers, 82 Union street, Boston, Mass. The subjects of the announcement are this firm's steam and hot-water heating apparatus, of which several illustrations are presented and a few particulars as to size and principal merits. Prominent attention is likewise given to Le Bosquet's Patent Regulating Damper, which is illustrated on the poster.

THE LAST NUMBER of the U. S. Heater Company's "Postal Travelers" is given over to an account of their expansion tanks, for use with hot-water heating apparatus. These tanks are described as made of heavy boiler steel and tested to 200 pounds pressure. An illustration is presented, and likewise table of sizes and capacities and prices.

THE RAYMOND & CAMPBELL MFG. COMPANY of Middletown, Pa., are meeting with a large demand for their Sun boilers. Their large orders received since March 1 include three boilers for H. M. Kaufman, Windom, Lane County Pa.; eight for S. F. Littlefield, Wakefield, Mass.; three for F. T. Davis, Portland, Me.; eight for A. J. Rogers, Paterson, N. J.; four for St. Louis Steam, Heat and Ventilating Company, St. Louis, and four for H. Gray, Washington, D. C. The company have on exhibition in Chicago at the store of Rendtorff & Co., Lake street, two of their improved boilers, where they will remain from May 20 to June 3. They will then be removed to the Revere House, corner of Clark and Michigan streets, where the convention of the Master Steam and Hot-Water Fitters of the United States is to be held. Mr. Lindemuth, the patentee of the boilers, will be present at the convention.

GIBSON, SCOTT & Co. have just commenced business as steam and hot-water engineers and contractors at Ridge avenue and Buttonwood streets, Philadelphia. The firm is composed of W. C. Gibson, A. W. Scott and J. V. Adair, and with a long experience, obtained through a connection of some years with a large Western firm in the same line, should find lots of opportunities to place their work.

J. P. SCHAFFER is now located right in the midst of the heating trade, at 18 Wood street, Pittsburgh, Pa., in a large five-story building. The first floor has the office and is used to display samples of the Black Hussar steel ranges, the Novelty hot-water circulator, the Novelty hot-air furnace and a line of heating and cooking stoves and open grates. The basement is used for storage and has the tools and pipe-cutting machinery necessary for the erection of hot-water heating plants. The second, third and fifth floors are used for storage, and the fourth floor for a tin and sheet iron shop, for which, in addition to its present equipments, some special machinery is being constructed. The present location is selected to meet the requirements of a business growing as the result of the superior service rendered. Having made a specialty of heating with hot air, the use of high grade tin plate in the work and sound judgment in laying out the plan have resulted in a success which requires large quantities of registers and heating goods by the carload. One of Mr. Schaffer's inventions is his patent annular water pan for hot air furnaces which moistens the air that passes through each hot-air pipe equally.

M. E. HERBERT, 186 Van Buren street, Chicago, has the contracts for steam heating in the following buildings: Waukesha Hotel, Sixty-fourth and Hope streets; Renfast Building, 72 flats, Fifty second street and Cottage Grove avenue; Yale Hotel, Sixty-sixth and Yale streets; Rothschilds' Apartment Building, Forty-first street and Indiana avenue; Williams' Building, Twenty-third street and South Park avenue; Hasselroth Building, Chicago avenue and Franklin street; Arizona Building, 12 boilers, Forty-second street and Lake avenue; Potomac Building, Thirtieth street and Michigan avenue; Albemarle Building, 3801 Lake avenue, and Kedzie Building, Clark and Randolph streets.

A RECENT NUMBER of the *Rural American* contains a very flattering notice of the Royal hot-water heater manufactured by Hart & Crouse, Utica, N. Y. A cut is presented of the heater and a description is given, special emphasis being laid upon the meritorious features of its construction.

Prize Competitions

$25.00.

Prize Competition No. 24.

SUBJECT:

Short Methods of Figuring Discounts.

Merchants may be assumed to be able to arrive accurately at the cost of an article, list and discount being given, but not all are familiar with the shorter methods by which results may be quickly arrived at and more complicated questions in discounts be solved. This competition is designed to draw out a description of short methods of figuring discounts. Among the subjects which may be touched upon are the following:

Finding the net cost, list and discount being given;

Finding the percentage of profit, net cost and selling price being given;

Finding out at what price goods should be sold to secure a certain percentage of profit;

The extent to which it is practicable to use a single discount which is equivalent to two or more discounts.

Other matters will naturally occur to those entering this competition and we shall be glad to have any information on this subject which will be of service to the trade.

This competition will remain open until June 3, 1893.

The following prizes will be awarded:

First prize	$12.50
Second prize	7.50
Third prize	5.00

The prizes will be awarded for answers which, in the judgment of the committee of award, are most suitable for publication and of the most general interest.

We reserve the privilege of extending the time on any competition in case the contributions received are not of sufficient number or merit for the committee to award prizes. These competitions are open to every one, and it is hoped that there will be a general response from business men. We shall have the privilege of publishing any or all of the contributions received.

Replies are to be received not later than June 3, 1893. They should be addressed as follows:

DAVID WILLIAMS,
96–102 *Reade street,*
New York.
Prize Competition No. 24.

The Competitions which have closed are now in the hands of the Committees of Award, who are giving careful attention to the claims of the different contributions. From the number of these and the evident merit of not a few of them, we are assured that a great deal of valuable information and suggestion will be put at the disposal of the trade.

The Weekly Prize Competitions noted below are now before our readers and remain open until the dates named:

No. 21. Closing May 13.
The Safety Line in Credit Business.

No. 22. Closing May 20.
The Best Manner of Presenting and Collecting Book Accounts.

No. 23. Closing May 27.
Three or more Subjects for Prize Competition.

No. 24. Closing June 3.
Short Methods of Figuring Discounts.

Another subject will be announced in our next issue.

Sealed proposals will be received at the office of the Supervising Architect, Washington, D. C., until May 31 for furnishing and erecting complete in the United States Court House and Post Office Building, Trenton, N. J., either a hydraulic passenger elevator, including pumps, tanks, piping, car, closure of well hole, &c., or steam passenger elevator. Also a new steam boiler, injector, smoke stack, &c., according to the drawings and specifications, copies of which may be had at the office of the Supervising Architect, Washington, or the Custodian at Trenton.

An enormous microscope was constructed in Munich, according to the *Annales Techniques*, to be exhibited at the Columbian Exposition. It has a normal magnifying power of 11,000 diameters, which can be increased to 16,000 by the medium of an electric light, which throws the image on a screen. In order that the heat of the lamp may occasion no expansion of the metallic parts of the armature, and consequently displace the focus of the lenses, a bronze cylinder containing liquid carbonic acid is so arranged that a little liquid escapes when the temperature reaches a certain point, and by its evaporation reduces the armature to a normal temperature.

Florida is fast coming to the front in the canning business. New canneries are reported this month as being established in Jacksonville, Key West, Tampa, Pensacola, Fernandina and other points.

STOVE TRADE NOTES.

The Stove Exhibit at the Fair

A representative of *The Metal Worker* paid a visit to the World's Fair last week for the purpose of writing up the stove exhibits. Much to his disappointment he found these exhibits still very incomplete. In some cases manufacturers have done exceedingly well, having erected tasteful pavilions and arranged a fine display of their goods. But the section was by no means complete. Some pavilions were in course of erection by belated exhibitors, others were being painted and decorated, while quite a number were partly filled with exhibits in various stages of disorder. Not a few spaces were occupied by packing boxes wholly unopened. The enterprising manufacturers who had pushed work so as to make a creditable showing on opening day were disgusted with the work going on in the immediate vicinity, which created considerable dust and dirt and excited apprehensions of injury to handsome articles splendidly arranged to dazzle the eyes of visitors. It was like portions of a carpenter shop fitted up with parlor furniture. When all exhibits are finally in place and all work is completely done there will probably be some retouching needed by the "early birds" on the scene who have not "caught the worm," but have caught lots of annoyance from the late comers.

An Army Cooking Stove.

It appears that for some years past the Adjutant-General of the National Guard of the State of Pennsylvania has endeavored to procure a suitable stove for cooking the rations issued to the men when in camp. The experience at Homestead, as well as at all previous encampments, showed that a large percentage of the rations was wasted and the rest deprived of much of its nutriment by reason of the primitive facilities afforded. In January there was a meeting of the Fourth Regiment officers and a committee appointed to devise suitable cooking apparatus for the companies of the regiment. This committee delegated one of its number to have a stove constructed which would in all particulars meet the requirements of the case. In this work the services of Boiler Inspector James Schrader of the Philadelphia & Reading Railroad Shops, and George Schimpf, a boiler maker and steam fitter, were secured and the stove constructed. At a recent test the stove was found satisfactory in every particular. The stove is made of ¼-inch steel and stands 26 inches high, is 26 inches wide and 36 inches long. The fire place is 12 inches wide, 26 inches high and 26 inches deep, and has a lining of iron with an air space. The opening of the fireplace is on the side of the stove opposite from the oven, so that the cook is not annoyed by projecting sticks of wood, there being three sides of the stove free from obstruction. The oven is 18 inches high, 18 inches wide and 24 inches deep, the construction being such that the heat passes entirely around it before reaching the flue. The door opens out upon the ground, a swinging handle bringing it on a level and forming a table or shelf for the convenient removal of dishes. The stove pipe telescopes, and in shipment can be carried in the oven, together with the stove lids. Handles can be placed on the corners of the stove, so that it can be readily carried by four men. The claim made for this construction is that it effects a great saving of fuel, and cooking operations can be conducted in less time than with the stoves which have heretofore been employed for the purpose.

Abendroth Brothers' Display at the World's Fair.

Abendroth Brothers, proprietors of the Eagle Iron Works, and with offices located at 109 and 111 Beekman street, New York City, have a very attractive exhibit at the World's Fair, now in progress in Chicago. Before the stoves were forwarded to their destination they were placed on exhibition at Portchester, where the foundry is located, in order that they might be inspected by those interested. The exhibit consists of selections from the company's lines of cook stoves and heaters, a prominent feature being the York Grand fire place heater, similar in design, we understand, to the one purchased by the Siamese Prince for the palace in Bangkok. A companion of this stove in elegance, finish and style is the York Queen fire place heater, hundreds of which are being placed in apartment houses in New York City. These stoves are finished in the highest style of the art and decorated with nickel, art tile and jewel embellishments, in what may be designated as the renaissance style. There are also several very attractive ranges of the York series—the Norfolk, the U. S. range, the Badge, the Linwood, Pride of America, the 88 York, the Andrus water heater and the York furnace. The exhibit, we understand, is in the Horticultural Building and occupies a space 16 x 8 feet. The platform upon which the stoves rest represents a tessellated pavement. The groupings are pyramidal in form, surmounted by the trade-mark of the company. This trade mark is 3 x 4 feet in size, and is held in position by wrought-iron framework. The central feature of the display is the Columbian vase, 55 x 30 inches in size, the finish being mostly in galvano-bronze. There is also the Venus vase, 56 x 44 inches, in galvano copper bronze; the Chase vase, 64 x 50 inches, finished in galvano-bronze and of a style which may be designated as mediæval gothic; the Flora vase, the Amazon or Greek vase, finished in verd antique, with polished brass posts and banners; the Grace, finished in old brass; the Grecian or Arcadian vase, with Acanthus decoration; the Florentine, finished in cream and gold, and the Gem, with pedestal finished in white enamel. There are some very fine specimens of portrait sculpture in connection with this exhibit, the designer and modeler being George Beck, who for many years has been connected with the Eagle Foundry. The company named have a very artistic display, and it is one which is likely to attract attention, not only of members of the stove trade, but of all who admire beautiful workmanship.

The Stove Conventiom.

An Ohio stove man has been thinking deeply over the approaching convention—so deeply that his thoughts have arranged themselves in verse, and he sends us the following effusion, *à la* Kipling:

"Now, what's the molder howling for?" the big stove maker said.
"He wants more pay; he wants more pay," his secretary said.
"But what's the use of howling so and shaking of his head?"
"Because he wants his rights, you see," the secretary said.
For the molders are a-talking and a-cussing all the day,
And they say they will not work for their old wages, any way,
And if the makers don't give them a sure increase of pay
They're going on a strike some fine June morning.

"What makes my cash box feel so light?" the big stove maker said.
"Folks don't buy stoves; folks won't buy stoves," his secretary said.
"But how am I to pay my men and give them steady work?"
"That's your lookout; that's your lookout; pay day you cannot shirk."
For the molders are a-talking and a-cussing black and blue;
They don't care if they work or not, but say that if they do
They want a straight fifteen per cent. more than in 'ninety-two
Or they're going on a strike some fine June morning.

"Who's that lean chap out at my door?" the big stove maker said.
"He's your Dakota salesman, sir," his secretary said.
"Why don't he stay out on the road, and sell, and sell, and sell?"
"He hasn't sold a stove this month, and don't feel very well."
For the farmers are a-talking and a-cussing black and blue;
The rain it rains when snow don't snow, and winter ne'er gets through;
So that things look bad for wheat and corn, likewise potatoes too,
And there'll mischief be to pay some fine June morning

"But who's that bogie man out there?" the big stove maker said.
"He calls himself an editor," his secretary said.
"Well, then, why does he gnash his teeth and talk so very loud?"
"Because he wants some 'ads' right now and wants 'em in a crowd."
For the papers must be printed and the printers' bills be paid,
Then be carried through the mails and on each stove man's desk be laid
To instruct him how to think and act and how to run his trade,
So "ads" must come or there will be a circus some June morning.

"Oh, what's that row offends mine ears?" Chicago's mayor said.
"The stove men have a meeting, boss," his secretary said.
"But do they howl and yell like that whene'er they come to town?"
"Oh, no. But now they're in a row and got somebody down."
For the stove men are as meek as lambs when things go the right way,
But when they get their dander up the man should go and pray
Who thinks they don't know how to fight, and therefore that he may
Pull all their noses out of whack some fine June morning.

Exhibits of Heating Apparatus.

From the official catalogue of the exhibits of the World's Columbian Exposition we note under Group 115 of the Manufactures and Liberal Arts Building the following list of exhibitors of heating and cooking apparatus. It will be noticed that the boilers, furnaces, cook stoves, &c., are under one grouping:

Abendroth Brothers, New York.
American Heating Company, Rockford, Ill.
American Radiator Company, Chicago.
Beckwith, Estate of P. D., Dowagiac, Mich
Bailey Oven Company, Mansfield, Mass.
Bucks Stove & Range Company, St. Louis, Mo.
Buzzacott, Francis H., Fort Sheridan, Ill.
Chapman, H M , Chicago.
Chicago Clothes Dryer Works, Chicago.
Chicago Stove Works, Chicago.
Clark, Geo. M. & Co., Chicago.
Co operative Stove Company, Cleveland, Ohio.
Collins & Burgie Company, Chicago.
Co-operative Foundry Company, Rochester, N. Y.
Cortland-Howe Ventilating Stove Company, Cortland, N. Y.
Cribben, Sexton & Co., Chicago.
Daemicke, Paul J., Chicago.
Dangler Stove & Mfg. Company, Cleveland, Ohio.
Daggett, W. A. & Co., Vineland, N. J.
Devlin, Thomas & Co., Philadelphia.
Enterprise Mfg. Company, Philadelphia.
Excelsior Mfg. Company, St. Louis.
Farquhar Heating Company, Chicago.
Fuller-Warren Company, Milwaukee, Wis.
Gorton & Lidgerwood Company, New York.
Goodell Company, Antrim, N. H.
Graff & Co., Chicago.
Green, Mrs. M. A., Mountclair, Col.
Griffing, A. A , Iron Company, Jersey City, N. J.
Hambel, Mrs. A. J., Chicago.
Hall, Whitney & Co., Boston.
Howard Thermostat Company, Syracuse, N. Y.
Huette-Barler Mfg. Company, Chicago.
Jackson, Edwin A., & Bros., New York.
Johns, B. B., Philadelphia.
Kahn, F. & L., & Bros., Hamilton, Ohio.
Kelsey Furnace Company, Syracuse, N. Y.
Lawton, Mrs J. M., New York.
Magee Furnace Company, Boston, Mass.
Mason & Davis Company, Chicago.
Meisselbach & Bro., Newark, N. J.
Michigan Stove Company. Detroit, Mich.
Milford Mfg. Company, Milford, Ohio.
Miller Range & Furnace Company, Wm., Cincinnati, Ohio.
Milwaukee Gas Stove Company, Milwaukee, Wis.
New Era Fuel Appliance Company, Chicago.
Northwestern Stove Repair Company, Chicago.
Pease Furnace Company, J. F., Syracuse, N. Y.
Peninsular Stove Company, Detroit, Mich.
Powers Duplex Regulator Company, Chicago.
Pugh & Grosvenor, Casselton, N. D.
Rathbone, Sard & Co., Chicago, Ill.
Reading Stove Works, Reading, Pa.
Resor & Co., Wm., Cincinnati, Ohio.
Richardson & Boynton Company, Chicago.
Ridgway Furnace Company, Boston, Mass.
Ronalds & Co., New York.

New Acorn Stoves.

Several handsome new ranges have just been brought out for this season by Rathbone, Sard & Co., Albany, N. Y. They are known as the "square oven series," and are both attractive and serviceable. It is claimed for the square oven feature that there is no useless space; that every part is available for baking, and that there is as much room at the top as on the bottom. The National Acorn, with square oven of extra size, is massive in appearance and of pronounced design. The decoration of the oven front is bold with deeply carved ornamentation, and the fire-box front is fine. The base is high and broad, being something of a departure from the ordinary. The trimmings consist of a novel form of oven door panel, with tile; nickel oven shelf, nickel towel bar and nickel knobs. The grate and fire box construction is a new feature. The new system operates as follows: A cog is slotted on the inside in two places, and, when slipped on the grate shank, these slots are engaged by two "nibs," which hold the cog and prevent its turning. A loose collar is then put on, and a small plate or cover is bolted over the ends of the grate bars, preventing the collars and cogs from getting out of place. The grate bars can be drawn out of the fire box door, and bricks or water front need not be changed. The grate itself is of new construction. Between the teeth the spaces are entirely open, giving a double draft, and permitting all loose ashes to drop easily into the ash pan without shaking the fire. The top is a double expansion one, with ventilated and lined covers and centers, reversible pipe collar, check damper, broad polished edges and full flush reservoir top. The oven is square and heated on five sides. The Acorn system of ventilation is used. The flue system is all sheet. The high shelf is new this year, large and handsome, with tight back and nickel tea pot shelves.

The Magnet Acorn, with a square oven, is of new design, the carving being of an elaborate pattern, and, in combination with nickel and tile oven-door panel, nickel outside oven shelf and other ornamentation, makes a very pretty range. It has a full width top, with broad, polished edges; flush reservoir top extending from front to back; reversible pipe collar and reed check damper; damper handle and rod removed from fire; swinging broiler door, with check damper; square oven, ventilated with fresh air; removable duplex grate with equalized draft; large reservoir heated from bottom; extra size ash pit and pan; patent oven door opener; high carved base. The Puritan Acorn is a contrast to suit those who prefer a quiet style in design. The carving on the oven door consists of four pieces of scroll work running from the corners, with rounded lines in plain cast-iron between the corners. There is a modest nickel panel on the door. This treatment in design is followed on the fire-box door and reservoir end, substituting plain iron for nickel. The base is a rich one. It has the prominent and substantial features in its mechanism. Both the Magnet and Puritan Acorn ranges have the patented removable duplex grate and the system of ventilation.

ODD PLATES.

The John Van Range Company, of Cincinnati, Ohio, report an active demand for kitchen outfits and culinary appliances. They at present have a number of orders on their books, and have recently installed complete kitchen equipments in buildings located in different sections. Prominent among the number may be mentioned the Clifton House of Chicago; the Government Mess Hall at Fort McPherson, Ga.; the Clemson Agricultural College at Fort Hill, S. C.; the Hotel Luehrmann at Memphis, Tenn.; the Windsor Hotel at Bloomington, Ill.; the Kenton Club at Louisville, Ky; the New York Kitchen at Spokane, Wash.; hotels at Hot Springs, Va., and Logansport, Ind.; the Government Mess Hall at Fort Bliss, Texas; the Kenwood at Chicago, and the Albany at Denver, Col.

In referring to the apparatus for heating and ventilating rooms recently patented by William H. Stuyvesant of Brookline, Mass., an error occurred in the spelling of the name, which is the explanation for calling attention to the matter again. The heater is made of Russia iron and stands 2 feet 6 inches in hight. The heat is supplied by three lamps placed on the floor, the cold air being brought in from outside. As it reaches the heater it is distributed into four 2¾ inch flues, which are located immediately over the lamps. The products of combustion and the foul air of the room are carried off by means of a side flue, specially arranged for the purpose. This heater is referred to as being portable, inexpensive and economical. Mr. Stuyvesant states he has been able to keep a room 12 x 16 feet in size in a comfortable condition during the coldest weather by the use of this device. The heater may be operated with oil lamps or gas, as may be most convenient. The invention is the result of Mr. Stuyvesant's investigations into the best plan for warming a certain room in his house, concerning which he had some difficulty last winter. We understand that Mr. Stuyvesant has already received a number of orders from leading scientific institutions in the country for samples of his heater, as it is claimed that it will be an economical and effective way of heating and ventilating dormitories in college buildings.

Floyd, Wells & Co. of Royersford, Pa., state that Robert Kearns is just starting out on a trip through New York State and the Northwest and C. W. Wagoner is to visit Ohio in the interest of their stoves and ranges, which they keep abreast of the times in constructive features and embellishments.

President Wm. L. Essick of the Keystone Meter Company of Royersford, Pa., still devotes his ability to producing goods that claim the attention of many of his old customers in the stove trade. In many cases the stove man is a gas fitter, and as such is interested in the Keystone meter.

The Sioux City Stove Works, which became financially embarrassed through the failure of a large concern in Sioux City, Iowa, passed on May 3 into the hands of a United States Marshal, who took possession on a writ of attachment procured from the United States Court by the Massachusetts National Bank of Fitchburgh, Mass., to secure a claim of $15,000.

We learn from a London exchange that in the course of a recent lecture on neglected points in domestic economy, by Dr. A. T. Schofield, an eminent English hygienist, the possible utilization of electricity for cooking purposes was demonstrated with good success. One of the apparatus provided was a small electrical stove—much like an ordinary gas stove in appearance; sundry grilling plates and various other patented appliances for

boiling and baking were also shown. The heat was produced by sending the ordinary electric current through a network of fine resistance wires, which were imbedded out of sight in the bottom of the saucepan, or in other cases on the side of the stove.

THE BUCKWALTER STOVE COMPANY of Royersford, Pa., are bringing out a medium priced square parlor stove of entirely new design that they claim is worth while to see before placing orders for a fall stock.

REPORTS from Salem, Ore., are to the effect that the State Board are considering a proposition for the purchase of a stove foundry, as provided by the last legislature, so as to give employment to the increasing number of convicts.

W. F. HABICHT celebrated the thirty-third anniversary of his birth by entertaining five of his nearer friends at a planked shad dinner at the Buena Vista Hotel, Gloucester, N. J. The well-known effect of a fish diet and a long connection with the house of F. M Borden & Bros. of Philadelphia will enable him to correctly interpret the most obscure order for Eastern Pennsylvania store repairs.

A VERY ATTRACTIVE CIRCULAR, printed in two colors and carrying beautiful illustrations of the Golden Rule range provided with horizontal circulating boiler, reaches us from A. Weiskittel & Son, Baltimore, Md. The Golden Rule range is a first-class construction, the manufacturers claiming that it is easy to set, can be moved by simply disconnecting the pipes and occupies less space in the kitchen than would be the case if a vertical boiler was employed. The range has sheet flues, patent oven door opener and corrugated tin lining to the oven doors. The ornamentation is of a very neat character, the embellishment of the doors of the warming closet and oven being especially noticeable. Two sizes are made, one having a 16 inch and the other an 18-inch oven.

THE MARCY STOVE REPAIR COMPANY have taken possession of their new five-story building at 74 Beekman street, New York, where they are in position to handle all orders which the trade may see fit to intrust to them. The managers of the concern, Messrs. Hauser & Dennis, are old stove men and understand the business in all its details The volume of trade has increased to such an extent, we understand, that additions have been made to the number of clerks employed.

WILLIAM HOWE of Cortland, N. Y., with several other manufacturers, has been in Niagara Falls, N. Y., making arrangements to secure considerable land. If the project is successful it is said that the Howe Stove Works of Tallapoosa, Ga., and several other industries will be located there.

"WE PROPOSE to get out a new catalogue of the Continental line of stoves, ranges and furnaces, showing all of our new goods," comes as a suggestion from the Buckwalter Stove Company of Royersford Pa. The catalogue will be ready about July 1 and the goods about August 1.

WEIR STOVE COMPANY, Taunton, Mass., are showing to the trade a new range called Glenwood II., which is a departure from late styles and a decided improvement, especially in the way of decoration. Nickel ornamentation is largely dispersed with, and fine carved designs in black, with here and there a bit of nickel in the way of relief, make this range artistic to a degree. All the latest improvements are embodied in the new style, including draw-center grate, patent door opener and several small devices for convenience.

"THE WEST SHORE RANGE FOR 1893" is the title of a four-page circular which comes to hand from the Littlefield Stove Company of Albany, N. Y. The range has a new oven-door shelf fastened to the outside by a small key, which can be operated by the fingers. This permits the construction of different grate frame supports to convert them into ash chutes for the purpose of guiding all the ashes into the ash pan. The company have also brought out a new pipe shelf composed of three parts, and is made to form a portion of a new high closet if desired, the same doors being used as upon the company's old high closet. The smoke pipe passes up outside of the new closet instead of through it, and the double elbow required is furnished by the makers. The largest sizes of the range are now made both right and left hand, as are also various other sizes, which are enumerated in the circular. In this connection it is interesting to note the definitions given of what constitutes a right and left hand range. The left-hand range is said to be one which has its fire box at the left as one stands facing the oven door, while a right-hand range is one which has the fire box at the right when facing the oven door. The West Shore range is illustrated by means of a sectional cut and its main features of construction fully described. The company state that they manufacture and can promptly furnish 336 distinct sizes and styles of ranges for hard coal or wood and 96 sizes for soft coal, making a total of 432.

THE ALBANY PLANT of Rathbone, Sard & Company was slightly damaged by fire Tuesday of this week. It broke out in the japanning room on Rathbone street. Colonel Bowditch of the firm says that the fire will delay the working of the foundry for several days, but the loss will not reach over $2,000, and is fully insured. On December 6, 1887, a fire occurred in the same part of the plant, caused by the ignition of japan. The loss was then about $17,000, which was covered by insurance.

DIGHTON FURNACE COMPANY, North Dighton, Mass., are bringing out a new range which will bear the name Royal Winthrop. The range is described as having triangular or plain grate, drop door, nickel rail, and a feature is made of the ventilated door, which is lined flush and when dropped forms a handy shelf. Another important improvement is an arrangement which permits the removal of the grate without disturbing water front and lining.

THE J. F. PEASE FURNACE COMPANY, lately at the corner of Water and Fulton streets, New York, have discontinued that office. Their business for this territory is now in charge of Franklin & Burnham, as sales agents, at room 401, 284 Pearl street, New York. It has been the policy of this company to have their own men in charge of their business for some years, so that their heaters would be properly introduced and installed, and satisfactory results obtained. When this has been done they have given over the work to competent and reliable people to carry on. The James W. Birkett Mfg. Company, 351 and 353 Jay street, Brooklyn, have the agency for Long Island, Brooklyn and New York City and will have charge of the setting up of the Economy heaters, which will be supplied by Franklin & Burnham from their Brooklyn storehouse.

NORTH DIGHTON CO-OPERATIVE STOVE COMPANY, North Dighton, Mass., have added an elevated shelf and hot closet to their Prize Oak range, which is now made complete in all the various styles.

Stove Convention Topics.

The following circular has been addressed to the members of the National Association of Stove Manufacturers by Secretary Thomas:

The subjects which will be brought up for consideration at the forthcoming annual convention will be the following:

BY REPORTS OF COMMITTEES.

Cost Accounts, Standing Committee.
Stove Terminology, Holdover Committee.
Piracy of Patterns, Holdover Committee.
Transportation Rates, New Committee.
Prices, New Committee.
Local Associations, New Committee.
Finances, New Committee.
Good of the Association, New Committee.

BY PAPERS PREPARED FOR THE CONVENTION.

Consolidation, Lazard Kahn.
Co-operation, G. D. Gibbons.
Traveling Salesmen, C. S. Prizer.
Rights of Americans, D. W. Bell.
Cupolas, Their Construction and Use, W. J. Keep.
Credits, D. McAfee.
Credits and Reports, R. G. Rennolds.
The National Association, F. W. Gardner.

The president wishes those in attendance to previously prepare themselves by investigation and reflection to take part in the consideration of these topics for the enlightenment of the trade, so that our meeting may be fruitful in beneficial results.

Head's Iron Foundry.

We are indebted to Head's Iron Foundry, Utica, N. Y., for copies of catalogues which they are distributing to the trade, covering goods for the season of 1893. Particular attention is invited to the Standard and Rival furnaces, as well as to the combination heaters manufactured by the company. The catalogues are oblong in general shape, printed in two colors, and bound in paper covers. The opening pages of one of them are devoted to an illustrated description of the Standard four-dome furnace, following which attention is invited to the Rival, furnished with steel radiators, and to the Standard Junior, a four-dome heater, which has been improved for 1893. This furnace, we understand, is substantially the same as the company's Utica Standard four-dome heater, except that a pipe is taken from each of the two front domes, through which the draft passes into a lower steel gas-tight radiator, and, after traveling to the rear of this radiator, enters the smoke pipe, whence it escapes to the chimney. A damper is placed in the smoke pipe at the rear of the four-dome radiator, and after the fire is started the damper is closed, the draft being diverted through the lower radiator. Above the latter and level with the top of the ash pit are placed perforated plates of sufficient capacity to feed all registers employed. The arrangement of parts is such that the smoke pipe where it enters the chimney is cool, for the reason that the heat generated from the fire is utilized to the fullest extent before the products of combustion escape to the chimney. The catalogue also gives attention to the Rival Junior, which has been improved for this season. The makers claim that as now presented to the trade the furnace is greatly increased in efficiency, and, while economical in the use of fuel, a steady, even temperature can be maintained. The catalogue gives a very full description of the manner in which the furnace operates and presents a picture with the outer casing of the heater broken away, showing the position of the parts. The Standard Air Blast furnace for soft coal and illustrated descriptions of the reverse motion grate, the four-dome radiator and of the grate bars employed, are features of the publication. The closing pages are given up to the Standard hot water combination heater and the Standard steam combination heater.

TRADE REPORT.

The Iron Market.

The events of the past week have not been conducive to improvement in the Iron trade, yet it is encouraging to find that it held its own, and from some points of view promises to do a little better than that. Stringency in the money market is being felt both East and West, and is causing buyers to place their orders very sparingly, and buying in limited quantities only will doubtless be largely the policy until the money market has again become easier. There can be no question that with a fairly easy money market Iron would improve, but as this is one of the things that cannot be absolutely depended upon, Iron must take its chances and go with the stream. From present appearances a favorable outcome is probably not unwarranted. There is plenty of business and nothing to interfere with a quick movement so far as regards stocks on hand. Consumers in all departments are more than usually dependent on immediate purchases to meet current requirements. Prices are firmer in Pig metal, weaker in Steel Billets, but steady in the finished article. The demand promises to be large, providing there are the usual bank facilities, but quite a large amount of business is held in abeyance, pending more definite knowledge on that feature of the situation.

Pig Iron—In the New York market is quiet, and while standard brands are holding their own very well, outside Irons are still pressed for sale. We quote Northern brands at $14.50 @ $15.25 for No. 1; $13.75 @ $14.50 for No. 2, tidewater. Southern Iron, same delivery, $14.25 @ $14 50 for No. 1; $13 @ $13.50 for No. 2, and $13.25 @ $14 for No. 1 Soft.

Good Irons are scarce in the Philadelphia market, and holders of such have no difficulty in securing full market prices for anything they care to offer. In the majority of cases they have all the orders they want; and, while customers are not refused reasonable quantities, it is clearly evident that sellers would prefer being let alone until they can see their way a little further ahead. For the present sales are at figures as quoted herewith for Philadelphia and equivalent deliveries, with 25¢ @ 50¢ less on Southern brands at Harrisburg and intermediately to Baltimore:

American Scotch, No. 1X	$16.00	@ $16.50
American Scotch, No. 2X	15.00	@ 15.50

The molders' strike continues at Chicago, and is having a bad effect on business there. Local Coke Iron shows no new developments. A little better trade is noted in Southern Coke, but contracts are not large; none exceeding 500 tons have transpired. Lake Superior Charcoal maintains its strength on current transactions, which are confined to small quantities. Buyers are still holding off, for they have been unsuccessful so far in their efforts to depress prices. The recent failures are making sellers apprehensive, and they are now more disposed to cultivate the small trade than the favors of large consumers, in order to divide the responsibility over a greater area.

Lake Superior Charcoal	$16.50 @	$17.00
Local Coke Foundry, No. 1	13.75 @	14.25
Local Coke Foundry, No. 2	13.00 @	13.25
Local Coke Foundry, No. 3	12.75 @	13.00

In Southern markets the situation is unchanged as far as prices are concerned, but some of the stronger Iron companies which have refused to accept the prices current are now free to accept orders. There are rumors that concessions have been made on No. 2 Foundry. Southern Charcoal Iron is quiet; but there are inquiries which it is hoped may lead to a fair business at an early date. Lake Superior Charcoal Iron is selling to a moderate extent. Buyers do not seem disposed to make engagements far into the future, preferring to keep close to shore.

Foundry.

Southern Coke, No. 1	$13.25 @	$13.50
Southern Coke, No. 2	11.75 @	12.00
Southern Coke, No. 3	11.00 @	11.25
Ohio Soft Stone Coal, No. 1	16.00 @	16.25
Ohio Soft Stone Coal, No. 2	15.00 @	15.25
Mahoning and Shenango Valley	14.75 @	15.00
Hanging Rock Charcoal, No. 1	19.00 @	19.25
Hanging Rock Charcoal, No. 2	18.00 @	18.50
Tennessee and Alabama Charcoal, No. 1	15.50 @	15.75
Tennessee and Alabama Charcoal, No. 2	14.50 @	14.75

Metal Market.

Copper.—During the week under review dealings have been of ordinary character and moderate, all told. The leading Lake Superior producer's price for Ingot has been advanced to 11¼¢, but more than enough supply to fill current orders is found elsewhere at 11⅛¢, and occasionally bids of 11¢ are accepted. The popular quotation on round lots is 10⅞¢, and up to 10⅞¢ is asked for small parcels.

Pig Tin.— The conditions that prevailed a week ago exist at the present time and the weight of excessive supplies has meanwhile forced prices to a lower level. Speculation has been quite active at the decline, chiefly in contracts involving current month, June and July delivery, but purchases by distributors and consumers continue on very conservative lines. May delivery has dropped from 20½¢ to 20.35¢; June from 20.65¢ to 20.40¢ and later deliveries proportionately. Within two weeks' time there has been a decline of 60¢ ℔ 100 lb in price of July delivery.

Pig Lead.—Prices have been moving gradually downward, under the influence of freer offering and continued narrow outlet. The market is at present in a weak, unsettled condition, with deliveries from June to August inclusive offered at 3¾¢ and buyers very indifferent.

Spelter.—There has been somewhat freer offering of Western brands for late June and more distant future delivery, and with it some softening of prices. Spot stock is scarce and commands 4½¢. Prompt shipments are also firmly held at that price, but July delivery may be secured at 4 45¢, and deliveries further ahead at 4.40¢.

Antimony.—Of jobbing quantities there has been about the usual movement and prices have undergone little or no change. Current quotations are 10¢ @ 10½¢ for Hallett's, 10¼¢ @ 10½¢ for L.X., and 10½¢ @ 10¾¢ for Cookson's.

Tin Plate.—The market is without change. Business continues slow and there is little if any improvement in the demand for either prompt or future deliveries. Sellers' figures about the same as they were last week, but somewhat deficient in point of firmness. In the retail trade the improvement which it was anticipated would come with warmer and fairer weather is as yet barely perceptible. Stocks are not by any means heavy, but supplies of all grades are held in sufficient quantities to meet the small current demand. Rumors of cutting in prices are current.

Coal.

The Anthracite Coal trade is quiet, particularly in the Eastern trade. While the companies claim to maintain schedule prices, a good deal of Coal finds its way into market at a shade below, as for some weeks past, and the talked-of advance June 1, it is surmised, can be made only on paper. Prices, however, are helped by the interruption of mining by floods, a score of the Reading collieries having been compelled temporarily to suspend. Despite this drawback Reading shipments have been very large, and the total production shows an increase over the large business of 1892. A Scranton paper says: "The special feature is the increase in the Lehigh region, which for several years has shown a comparatively small gain. The returns from the Schuylkill region are also significant, as the increase they exhibit reflects the improvement in the business of the Reading company."

Stove Coal is $4.15, f.o.b., gross circular. Commission houses are allowed 10¢ ℔ ton extra commission, making 25¢ commission to them, of which they give the

retail trade 15¢. Bituminous Coal is very quiet.

A Reading official is quoted as saying: "It is absolutely necessary to shut down. The output is nearly 1,250,000 tons ahead of the output for the same period last year." Week's production, 844,113 tons; year, 13,222,025; increase, 1,188,833. Reading Coal tonnage, 378,000 tons. Pennsylvania Railroad Coal tonnage, 321,277 tons; Coke, 105,363. Bituminous Coal regions shipped as follows: The Norfolk and Western regions, 87,858 tons; Clearfield, 68,698; Huntington, 47,554; Beech Creek, 65,988. The excess of Soft Coal production for the regions above named over last year to date is 1,121,310 tons.

Chicago Report.

Scrap.—There is very little demand for Old Material. Dealers' buying prices are as follows:

	Per net ton.	Per lb
No. 1 Wrought Scrap	$12 50	....
Machinery Cast	10.00	....
Maleable Cast	7.00	....
Stove Plate (free of burnt)	7.50	....
Burnt Iron and Grate Bars	5.00	....
Sheet Iron and Hoops	4.00	....
Plow Steel and Breaking Stock	8.00	....
No. 2, such as Shovels, Hoes, &c.	4.50	....
Old Boilers—whole (Iron)	8.00	....
" (Iron)—cut in single Sheets and Rings	11 00	....
Old Gas-Pipe and Boiler Tubes	8 00	....
Cast Borings	4 75	....
Turnings	6.00	....
Horseshoes	12 50	....
Copper Bottoms	....	8¢
Copper Clips and Heavy	....	9½¢
Heavy Brass	....	8¾¢
Light Brass	....	4 ¢
Pipe Lead	....	3 ¢
Tea Lead	....	2¾¢
Zinc	....	3 ¢
Rubber	....	3 ¢

Anthracite.—Large dealers are beginning to order their stocks for the summer trade. We continue to quote carload lots of 12 net tons as follows:

	Egg, Grate.	Sto. and Ch.
Chicago, Ill	$5.35	$5.60
Milwaukee, Wis	5.35	5.60
Kansas City, Mo	8.55	8.80
Council Bluffs, Iowa	8.55	8.80
St. Joseph, Mo	8.55	8.80
Leavenworth, Kan	8.55	8.80
Omaha, Neb	8.55	8.80
Burlington, Iowa	6.85	7.10
Des Moines, Iowa	8.30	8.55
Davenport, Iowa	6.65	6.90
Dubuque, Iowa	6.65	6.90
Madison, Wis	6.85	7.10
St. Paul, Minn	7.85	8.10
Lincoln, Neb	8.70	8.95
Sioux City, Iowa	8.55	8.80
Aberdeen, S. Dak	8.60	8.85

Colorado Anthracite.

COLORADO FUEL & IRON COMPANY.

Denver	$8.00
Pueblo	8.00
Colorado Springs	8.00
Leadville	8.00
Cheyenne, Wyo	10.00
All points between Denver and Missouri River	9.35

C. A. Tanner & Co. and Smith, Van Horne & Co., hardware dealers of Oswego, N. Y., have consolidated under the style of the Oswego Hardware Company. They expect to elect officers next week. J. K. Smith is to be general superintendent of the mechanical department and E. A. Van Horne will look after the finances. Besides conducting a retail trade the concern will do a wholesale and jobbing business. The wholesale and jobbing department will be located in the Kinyon block, when rebuilt, together with the retail department. It is understood that travelers will be put on and Central and Northern New York covered. Both firms have been among the largest business houses in Oswego and are certain of success in the venture. The capital stock is $50,000.

CONDITION OF THE

Hardware Trade.

THE VOLUME OF BUSINESS in some sections has been diminished by the backward spring and the bad weather which has prevailed, but on the whole there is little reason for complaint. The market is characterized by little of the speculative element and purchases are confined for the most part to early requirements. In most lines of goods there is no difficulty in having orders filled as promptly as desired, but in some lines there is more or less delay. The tone of the market is steady, prices being well maintained, and in some lines, such as Bolts and Nuts, an improved tone is noticeable, while on the other hand some staple goods, like Nails, are slightly lower than heretofore. In some kinds of shelf Hardware prices are being somewhat strengthened by the action of manufacturers who have reached, or are attempting to reach, an understanding. There is some complaint in regard to collections, and the financial condition induces a conservative course on the part of careful business men.

Advices from Chicago.—The volume of business in the Shelf Hardware trade, which has been steadily diminishing since the spurt early in April, shrunk last week to the smallest proportions for years. The complaint of dullness is universal. Salesmen have returned from several Western districts, as they found it undesirable to continue to solicit business during the unfavorable weather and the wretched condition of the country roads, which has checked traffic. The weather is held responsible almost entirely for the dullness of trade. The fine prospects which were so glowing last month have completely disappeared, and everybody is now speculating in what the future has in store. It is feared that in the advent of more favorable weather the farmers will be so busy seeding that continued dullness will prevail in Hardware circles, making the remainder of May and perhaps June a steady per cent. of bad trade. Collections are exceedingly slow and money is tight. The heavy Hardware trade is in a little better condition than Shelf Hardware, but not very much.

Notes on Prices.

Cut Nails.—The Cut Nail market has developed little change since our last report. In the Eastern market prices are represented by the quotation of $1.10, which is now quite generally named for carload lots at mill, having been in a few cases shaded. Small lots from store in New York are quoted at $1.35 to $1.40. The Western market is in a more satisfactory condition, but there is some unevenness in quotations named by different mills in the same district. The volume of business is only fair.

Advices from Chicago.—Steel Cut Nails are in a little better demand, but the volume of business is by no means satisfactory to manufacturers. They quote factory lots at $1.30 to $1.35, Chicago, while small lots are selling from stock at $1.35 to $1 40.

Wire Nails.—The Wire Nail market is perhaps a shade weaker than last week, and the quotation of $1.50 for carload lots at mill is more generally made than at our last report, so that $1.55 may now be regarded as rather exceptional. The action of some of the mills in naming the former figure naturally induced others to follow, and the fact that nearly all the large jobbers are holding stocks purchased at lower figures has enabled them to meet or undersell the manufacturers' prices. The mills are generally well occupied on orders which are not, however, coming in as freely now as a few weeks ago.

Advices from Chicago.—Wire Nails are again irregular, manufacturers are no longer adhering to the uniform price which was established last month. Their trade has been confined almost entirely to carload lots, the large buyers being well fixed with contracts for some time to come. The trade is, however, not demoralized, quotations running about $1.52½ to $1.55, Chicago, for large lots from factory. Carload lots are selling at $1 60. Jobbers' prices are $1.65 to city trade, and $1.70 to $1.75 to country trade.

Barb Wire.—The Barb Wire market is quiet and without material change. We quote $2 45 to $2.50 for Four Point Galvanized in carload lots at mill. Small lots delivered in New York are quoted at $2.70 for Galvanized and $2.30 for Painted.

Advices from Chicago.—Barb Wire shows no change whatever, either in the character of orders or in selling price. Manufacturers' quotations are still $2.20 for Painted and $2.60 for Galvanized. Jobbers' quotations are $2.30 to $2.70, respectively.

Cordage.—Notwithstanding the collapse of the National Cordage Company there is very little change to note in the Cordage market. Whatever may be the outcome of the National Cordage Company's affairs, it is thought by well-informed parties that lower prices will not be the result, inasmuch as it has been recognized for some time that they have been selling at a loss, giving their attention, it is thought by many, principally to manipulations of the stock market, which proved so disastrous to their interests. Under proper business management, it is thought that the price of Cordage, especially in view of the condition of the Hemp market, must be higher. What the outcome of the present somewhat complicated condition of things will be is uncertain, as it is thought by some that the National Cordage Company will attempt to carry out their projects, while others regard this as improbable and suppose that the organization will go to pieces. The fact appears to be that the company attempted too much in their efforts to establish a monopoly in the manufacture of Cordage, while at the same time they endeavored unsuccessfully to obtain control of the Hemp market. Their failure in both of these regards, together with their attempts to float the company's stock, is regarded

as the cause of their downfall. The plants of many of the manufacturers are undoubtedly antiquated, old methods of making Rope having been superseded by new and improved machinery. Precisely what John Good's position in the market will be remains to be seen, but there appears to be little doubt that he will occupy an exceedingly influential position, and it is thought not unlikely that he will be a controlling factor in Cordage interests.

Wrought-Iron Pipe.—The Wrought-Iron Pipe market continues, as it has been for some time, in an unsatisfactory condition, owing to the low and irregular prices which are prevailing. The somewhat advanced list of prices which were adopted by the manufacturers April 13 are regularly maintained. The discounts remain about as before. The revised list of April 13 is given below:

Butt-Welded.

Inside diameter.							
Inch.....	⅛	¼	⅜	½	¾	1	1¼
Black.....	$0.04	.04	.04½	.06	.07½	.11	.14½
Galv.....	.05	.05	.05½	.08	.10	.14	.19

Lap-Welded.

Inside diameter.									
Inch..	1½	2	2½	3	3½	4	4½	5	6
Black..	$0.24	.33	.50	.64	.76	.90	1.06	1.28	1.65
Galv....	.28	.38	.57	.70	.90	1.05	1.31	1.60	2.00

Inch....	7	8	9	10	11	12	13	14	15
Black.....	2.10	2.75	3.75	4.75	6.00	7.00	8.0	9.50	11.00

It is understood that manufacturers are conferring as to measures by which the market may be put in a better condition and more remunerative prices secured.

Glass.—Nothing has transpired during the past week of especial interest in the Glass trade. Prices remain firm and unchanged, owing to the influence of the Glass associations. Jobbers who are not members of the National Window Glass Company are not disposed to cut prices, as consumers and dealers seem to have accepted the National prices as the ruling ones. The factories report themselves busy, but from the comparatively light demand for Glass from dealers it would appear that factories are working on contracts yet unfilled. The cold, rainy weather of the past two weeks has lessened the immediate requirements of the trade, while the extreme weather of the past winter and the backward spring have delayed building projects, so that the demand for Glass for new work may not come until later in the season. Collections are reported as being slow. No official announcement has been made as to the results of the meeting of the Executive Committee of the National Window Glass Company in Chicago during the past week. It is understood, however, that there is a movement on foot to revise the long list of prices, and that the new schedule will be established upon a higher basis than the present one. The scale of prices for next season's fire, the necessity of a larger number of apprentices in Glass factories from which to draw blowers to supply the demand for experienced workmen, and the time at which the factories shall stop work for the summer rest, are questions which require immediate attention. Plate Glass remains unchanged in price, though the demand has been somewhat lessened by the bad weather. The National Glass Company are working quietly, perfecting their organization among Plate Glass manufacturers. Prices on Glass remain unchanged, as follows: American Window Glass, 2000 boxes at one time, 80 and 10 and 10 per cent. discount; carloads, 400 boxes, 80 and 15 per cent. discount; less quantities than carloads, 80 and 10 per cent. discount. Freight allowed on car lots and over, not to exceed 17½ cents per 100 pounds; less than car lots, f.o.b. at shipping point. French Window Glass, 75 and 10 and 5 per cent. discount. American Plate ranges in price from 50 and 10 and 7½ per cent. discount to 60 and 5 per cent. discount. Imported Plate Glass, 60 per cent. discount to 60 and 10 and 5 per cent. discount.

Trade Notes.

L. Schwartz, 187 South Fifth avenue, New York, makes a specialty of heavy Ash Cans, which he calls Engineers' Ash Cans. In addition to being made of heavy material they have a heavy band at the top and bottom, and at the bottom on the under side they have an inside band of angle iron. Heavy handles on each side make them well suited to the purpose and the usage they get.

The Zucker & Leavitt Chemical Company, 12 Grand street, New York, are represented in the Industrial Exhibit of the New York Press Club Fair by one of their Electric Motors.

McLeod, Ward & Co., 91 Liberty street, New York, are now prepared to furnish their Fan catalogue, which specially treats of Ceiling Fans for cooling. Very appropriately, in view of the approaching season, the catalogue says "keep cool" and it claims that the Van Houten Rotary Ventilating Fans are the best made, and of elegant design and finish, adapted to be run by steam, gas, water or electric motors. Ventilating churches, factories and all kinds of large buildings by either exhaust or pressure fans their engineers accomplish with results that are highly satisfactory. The Lundell motor is one of their newest motors and specially adapted for use with Cooling Fans, being securely fastened to a new Fan Motor Staud, from which the power is transmitted by pulley and belt to the Fans. The setting of Electric Motors is a feature of their business and they install them to run ventilating fans, elevators, pumps, machinery or cranes, either traveling or jib. They furnish Motors from 1 to 100 horse-power. The following are a few of the various uses for which they have set Motors: David Brown, 63 Beach street, New York, 1 horse-power to run printing press; Adams House, New York, to run Ventilating Fans in dining room and kitchen; N. S. Kaplan & Co., 369 Broadway, New York, 6 horse-power to run elevator; Lawrence, Turnure & Co., 52 Wall street, New York, 1 horse-power to run Exhaust Fan.

Eppelsheimer & Co., 164 Bleecker street, New York, make a specialty of Molds and utensils for hotels, restaurants, confectioners, ice-cream makers and chocolate manufacturers. They say that previous to their entering into the manufacture of Molds the leading confectioners imported those of the most artistic design, and that it was necessary to give at least four months' time on special designs. In their shop orders have been executed in a week for designs which had to be modeled by an artist before the work of making the Mold could be started. They issue a 40 page catalogue of every thing the cook, pastry cook, confectioner and baker of the largest and most fashionable caterer requires, from an egg beater to a machine ice crusher, or from a copper stew pan to a cream freezer.

From C. F. & E. Biele, 45 and 47 West Broadway, New York, some interesting items concerning the Showcase trade are learned. A large portion of their varied designs of Showcases is sent to the South American countries, though shipments to Europe and Asia are frequent and large. The American-made goods, as compared with the heavy, massive productions of France and Germany, possess ample strength and are more attractive in their delicate appearance and handsome finish.

One of the old-fashioned shops where you can get almost anything done is run by John N. Blasi, 54 West Broadway, New York. He does blacksmithing, machine work, plumbing, steam and gas fitting, sets steam pumps, hoisting engines, elevators, and puts in electric call bells, besides doing jobbing of all kinds. Establishing the business in 1858, the many trades mentioned are the outgrowth of the demands made on a progressive man. He manufactures a line of store and warehouse trucks, dry goods and platform trucks, box presses and porters' tools and a platform elevator that runs by hand power.

The New York Steam Wire Works, operated by Hopkins & Co., at 90 West Broadway, New York, was established by James Hopkins in 1840. After following the business in the regular way for some years he patented the process of crimping heavy wire and weaving it into a diamond-shaped web, both being advances over the old square web where the cross sections of the heavy wire were fastened by smaller wires. The company now make some very handsome brass grill work for house and office decoration, besides an extensive line of wire goods. The seasonable goods now in demand are trellises, tree guards, mosquito netting and "chicken" wire.

Some complimentary observations on the World's Fair and an invitation to inspect their exhibit of "decorated art ware for the dining room" comes from Manning, Bowman & Co., 57 Beekman street, New York, on a tinted folder with a steel engraved frontispiece and a view of their factory. With it is a 16-page price-list in a seven-color effect, showing their Pearl Agate Pots with decoration, and some of their other specialties.

The Lightning Dasher Egg Beater Company, Toledo, Ohio, state that since January 14 last over 50,000 of their Egg Beaters have been sold and they are shipping daily from 100 to 150 dozen.

The Utility Churn and the Paragon Washer are the subject of an advertisement this week of the Olds Wagon Works, Fort Wayne, Ind. The appearance of the goods is shown by illustrations and the advantages are noted in the text.

Charles Thomas, 315 West Second street, Elmira, N. Y., successor to J. F. & E. R. Waugh, distributes a neat illustrated circular relative to the Waugh Circular Shears, well known to tinners and sheet-metal workers. Cuts show the Nos. 1 and 2 with bevel and squaring attachment, and the Nos. 3 and 5 Circle Shears. Price-lists are also given in the circular.

Silver & Co., on May 1, removed their office and factory to 304-310 Hewes street, Brooklyn, N. Y., their New York sample room and sales room being, after the same date, located at 20 Warren street. In making this announcement to the trade they state that eight years of continual progress, prosperity and success in the making

of Kitchen-Furnishing Goods and Household Inventions has compelled them to make these changes, as they had outgrown their old quarters. They now have largely increased facilities, with complete manufacturing plant especially arranged for the manufacture of their various specialties.

THE STARK MACHINE & TOOL COMPANY, Buffalo, N. Y., are building two Back-Geared Single-Action Power Presses, weighing about 15 tons each. They have also recently taken contracts for two of their 11-Foot Combined Foot and Power Shears, cutting No. 20 stock by foot and No. 14 by steam power.

THE COVER of the 1893 catalogue of the Niagara Stamping & Tool Company, Buffalo, N. Y., is of fire-cracker paper, and the printing in silver ink gives a very pleasing effect. The catalogue contains over 100 pages of convenient size, and is got up with much care, and evidently at no little expense. A fine grade of paper is used, with the advantage of bringing out the cuts well, and also making a good letterpress effect. In compiling this catalogue it has been the aim of the Niagara Stamping & Tool Company to associate their various machines so as to facilitate comparison. An alphabetical index begin the volume, and the notices of goods opens with illustrations of bar folders; then come forming rolls, sheet iron folders, Niagara incased machines, Raymond machines, stove pipe crimpers and beaders, double seamers, &c.; a large variety of tinners' stakes, and likewise tinners' small tools. In view of the very great number of articles noticed in the catalogue it will be impossible to give even a general enumeration. Suffice it to say that a very extensive line of tools and machinery for working sheet metal is presented, and it is interesting to learn that nearly all of the goods are manufactured by the Niagara Stamping & Tool Company. One large section of the book is given up to power presses, and a large assortment of tools and appliances for canneries is noticed toward the end of the volume. Altogether, it is a very elaborate, serviceable and interesting volume for those who are concerned in sheet-metal work.

A. G. MOORE & CO. are introducing to the Stove trade their Boston Petty Ledger, which is shown in an advertisement in another column, and which, it is claimed, is especially adapted for the use of stove and hardware dealers.

NOTICE IS ISSUED to the trade that the Booth Copper Company have succeeded to Booth & Son, coppersmiths, who were established 40 years ago. The new location of the concern is at 122 Adelaide street, Toronto, Ontario. Some of the specialties of the firm are Copper Range Boilers, Copper Pantry Sinks, &c.

THE PROGRESS STOVE & TIN WORKS is the name of a concern lately incorporated at Louisville, Ky., with a capital stock of $40,000. The incorporators include Lawrence Richardson, F. F. Henley and J. F. Murphy. Mr. Richardson, we understand, is at the head of the company, who recently purchased the plant at Twenty sixth and Rowan streets from the Irwin Mfg. Company.

A SPECIAL TRADE SALE of Cutlery is announced by Haydock & Bissell, 12 Murray street and 15 Park place, New York, among the Special Notices in this issue, the time of the sale being Tuesday and Wednesday, May 16 and 17. The sale will comprise several thousand dozen of Table Knives and Forks, Pocket Knives, Carvers, Butcher Knives, silver-plated Tea and Table Spoons, nickel plated Shears and Scissors, &c. It will also include 100 gross first quality Table Knives and Forks. This is referred to as the last sale of Cutlery for the spring of 1893 and is worthy the attention of Cutlery buyers.

J. H. MELLOR & CO., at 826 Fulton street, Brooklyn, make a handsome display in their showrooms with the different goods for which they are agents. Tiles, both plain and decorative, come from the Beaver Falls Art Tile Company, Beaver Falls, Pa., and Columbia Tile Company, Anderson, Ind.; Gas-Logs from W. H. Galloway, Philadelphia, Pa.; Grates and Fire-Place Linings from the Peerless Mfg. Company, Louisville, Ky.; Fenders, Andirons and Fire Sets from Frank H. Graf, New York, and Mantels from L. Schwartz & Co., Buffalo, N. Y. These goods are arranged with regard for the artistic that makes the store truly a beautiful place.

THE CAMBRIDGE IRON & STEEL COMPANY, Cambridge, Ohio, manufacturers of iron and steel sheets, have now in course of erection a building 74 x 143 feet in size, which will be used for a galvanizing plant, in which the Bayliss process of galvanizing will be installed.

THE HANDSOME steel office desk made by Christian D. Then, 589 North Clinton street, Rochester, N. Y., which was illustrated recently in our columns, appears to have attracted attention on the other side of the water. *The Ironmonger* of London reproduces the cut and description of the desk in its issue of April 29, with the suggestion that sheet-metal furniture of this kind would be highly appreciated in India and other hot climates, where white ants soon play havoc with ordinary wood furniture

JOHN KANNOFSTKY, JR, recently moved his tin and sheet-iron business to a new shop at 486 Pearl street, New York, where he has better accommodations.

LUFKIN RULE COMPANY, Saginaw, Mich., have engaged as their direct representative C. M. Avery, who is well and favorably known in the jobbing Hardware trade. The company advise us that their new line of high quality Reliable and Rival Steel Measuring Tapes are meeting with a favorable reception at the hands of the trade, as evidenced by increased orders for the goods.

BOAS BROS., 80 Beekman street, importers of Enameled Kitchen and House-furnishing Ware, are about to move into more extended quarters, having secured the first and second lofts at 235 Greenwich street, on the corner of Barclay street.

THE WORKS of the Shepard Hardware Company, at Buffalo, N. Y., were entirely destroyed by fire on the night of May 8. The fire broke out at 7 o'clock in the north end of the company's main building, which was a very large one, being 550 feet long, 60 feet high and 262 feet wide, covering about 3½ acres of ground. The fire department responded promptly, but when it arrived the whole structure was a mass of flame and the intensity of the heat was such that it was almost impossible to approach the building. The offices of the company were located in another building, which also took fire; but, owing to the energetic efforts of the firemen, this building was not destroyed, and few if any of the company's important papers were burned. The main building was valued at $50,000 and was insured for $35,000. The loss on the contents, including machinery, patterns and stock, will, it is thought, reach $200,000, on which an insurance of $140,000 was carried. By the destruction of the factory over 400 men are thrown out of employment. The weekly pay-roll was more than $4000.

W. H. SILLS, 86 Lake street, Chicago, dealer in Mica, is distributing as souvenirs to the trade very pretty glass paper weights with views of the World's Fair buildings in colors. They are really artistic, and will be highly appreciated by all who receive them.

THE CHICAGO STAMPING COMPANY are now occupying new and commodious quarters, corner Congress and Green streets.

THE NUBIAN IRON ENAMEL COMPANY of Cragin, Ill., have been favored by the management of the World's Fair with a good order for Nubian to use on all the smoke stacks on the grounds. The company recommend it specially for such work as this, where metallic surfaces are exposed to the weather, while it is equally adapted to coating grates, stove pipe and other interior fixtures.

IN A NEAT CIRCULAR J. H. Williams & Co., Brooklyn, N. Y., manufacturers of Drop Forgings, announce that their exhibit at the World's Columbian Exposition will be found in section C of boiler-house extension to Machinery Hall. A full line of their standard products, as shown in their catalogue, together with a variety of special Drop Forgings of all kinds, will be in charge of their traveler, D. E. MacCarthy.

MAJOR E P. GRAVES, ex-county clerk of Bath, Steuben County, N. Y., has purchased an interest in the Corning Mfg. Company, makers of furnaces, tinware, &c. The business will be enlarged.

Comparison of Wages.

The wages paid per day in different trades seem strangely at variance with the amount of information that some workers must have and the responsibility they bear. This applies to the good workman, and not to the large body below the average or to the higher class at the top. Considering the money invested in tools by the carpenter and the supervision which he is expected to maintain over the other workmen on a building, his wages seem all out of proportion to those of the bricklayer. The tinner has stored away a fund of knowledge and can consult no higher authority in case of difficulty, yet has to meet difficulties requiring sound judgment, deep thought and a personal skill that is second to that required in no existing handicraft, but his wages, nevertheless, are not munificent. The plumber, without realizing it, is a veritable scientific cyclopedia compared with his frequent associate, the marble cutter, yet the latter receives much higher pay. It has been said that a man's business is as dignified as he makes it, but we are not prepared to admit that the old trades which are so indispensable have degenerated below the better-paid trades, as the difference in recompense would suggest.

Spiders and Flies.

Some astonishing figures presented in a report recently issued by the Inspector-General of Liquidations in Great Britain furnish food for reflection. The report in question is the first rendered under a new act of Parliament regulating the winding up, compulsory or otherwise, of public companies, and embraces those companies wound up during the year 1891. It shows that the loss to the British public who held shares in the collapsed concerns reached the enormous sum of $94,858,815. The Inspector states, moreover, that when the cost of winding up and other expenses are added, the total loss will probably approach $100,000,000. This is for one year only, and in but one country. Nothing could demonstrate more fully the extreme, almost criminal, credulity—or perhaps gullibility would be a more suitable term—of the investing public on the one hand and the unscrupulousness of some company promoters on the other hand. The mass of successful fraud represented in these figures is said to be great. In the majority of cases, too, the perpetrators escaped scot-free, only a few of the persons who shared in the plunder having come under the grasp of the law. Seldom is one brought face to face in so striking array with the facts of the case on this subject, and the lesson the figures teach us we should do well to lay to heart. For this condition of affairs is not confined to England. The old game of the spider and the fly is going on merrily in every country where the company promoter is abroad, and the matter touches persons of all conditions.

Small Investors.

A large proportion of the losses in the companies treated above represented, as we understand, the contributions of very small capitalists, many of whom had perhaps invested the savings of a life time of industry and frugality in what they had too easily been persuaded were sound and paying concerns. Those who have little to spare should think more than twice before investing even the smallest amount of capital in any concern whatever, however plausible and promising, of which they are not fully assured, by investigation and incontestable proof, that it is sound and that its promoters are reliable men as to character and of sound financial reputation. Such information can be readily obtained in all cities, from mercantile agencies, banks, or other sources which are above suspicion. It is mere justice to oneself, to those dependent on one, and to the community at large. The trouble is that men are everywhere found who will not put themselves out to take these necessary precautions, but are satisfied to take the word of those interested in getting their money, or who allow themselves to be deluded by the glowing terms of a prospectus. So that one is almost tempted to agree with the strong opinion of old Thomas Carlyle, that men are "mostly fools." Of course the tale of successful fraud above recorded only includes corporate operations which shelter themselves more or less under the cloak of the law. But the daily instances of men who ought to know better being fleeced by the more vulgar and petty arts of crooks and confidence men, and by means of tricks and impostures which are as old as the hills, show that much and continued warning is needed to induce people to shield themselves against the wiles of that unsavory host, be they promoters of bogus companies or petty sneak thieves, who live upon the money extracted from the pockets of others. It is said that the number of those who "live by their wits"—that is, dishonestly—in New York City alone exceeds 30,000. The inference is that the honest and hard-working balance of citizens are fools to allow them to do so.

Training of Tin Platers.

Are skilled workmen indispensable for the production of good tin plates? A manufacturer of American roofing plates, of whom we asked this question a few days ago, said his own experience demonstrates that they are not necessary—at any rate for terne plates. The authority in question has for several years given considerable study to the manufacture of tin plate, and is himself a competent plater. He has for some time tried the experiment of running a few pots with boys instructed in his factory, and has found that after two or three weeks' experience they are able to perform the whole operation of tinning roofing plates with complete success. Under the general supervision of a competent foreman, with tinning machines of a simple type, the boys in his factory are now turning out in large quantities roofing plates of a high grade, the demand for which is so great that, even while running the factory night and day, it has been found impossible to keep abreast of orders. By this means the manufacturer has been enabled to economize very considerably in the item of wages, and can put his plates on the market at a price which competes successfully with that of imported plates of similar quality. In addition to this he avoids the troubles and trials which seem inseparable from the employment of skilled labor. Of course this experience does not apply to the production of bright plates, for which some skilled labor seems to be at present necessary.

Disposal of Old Tin Cans.

"Wanted, 10,000 goats," is a head line in a recent issue of the Pittsburgh *Dispatch*, which is calculated to arouse curiosity. On investigation it is found that the ruminants are proposed to be supplied to the city Board of Health for the astonishing purpose of consuming the mass of old tin cans which is accumulating around the city garbage furnace—at least the *Dispatch* says this is the only method the superintendent can think of for ridding himself of a

daily increasing incubus! His furnace can't burn up the carloads of these articles which are daily thrown away from hotels, restaurants and private houses in the city and dumped into his care, and the digestive organs of goats are the only things, so far as he knows, strong enough to dispose of old tinware. However this may be, it is a solid fact that the question of disposing of the quantities of old tin cans thrown away in cities is one which is greatly exercising the municipal mind, and an effective solution of it is much to be desired. Surely, among the ingenious devices which modern invention has brought out for tuihzing waste matter of every kind, some method of disposing of this class of waste, which really contains valuable material, should be available. The difficulty lies largely in the bulky nature of the cans. Sash-weight makers use them in their manufacture, but as they only offer about $1 a ton for the material, and this on condition that the cans are flattened out, it is not much worth anyone's while to cater to that trade, as the operation of flattening a ton of cans would cost more than the sum offered for them. The tin and solder contained in the cans are of some value, and a number of methods have been announced for separating them. We do not know whether any one of them, however, has proved a commercial success, although it is said that the extraction of tin from old cans is carried on as a regular industry both in London and Paris. Some of the newest garbage cremating systems are claimed as capable of destroying old tinware, though how its annihilation is effected is not quite clear. Still, what is required is not destruction but utilization of this waste material.

Glass-Roofed Streets.

Some attention has been paid in English papers to a proposition for covering the principal streets of London with glass roofing, the roof being supported by iron girders, and ventilation being secured by free passage of air from end to end of the streets, and by the openings from the sides at street crossings. The object appears to be to keep the streets dry, which purpose would doubtless be measurably attained; but other inconveniences would be introduced. A street under glass would be intolerably warm in bright summer weather, and it would smell like a stable. To cover sidewalks with glass roofing would, however, be a real improvement in cities, keeping the sidewalks dry, conveying rain water into gutters much more effectively than the canvas awning now so much in vogue, and not interfering with that thorough and constant change of air necessary to keep city streets in a wholesome condition.

Electric Ventilation.

The use of fan blowers driven by electric power has become quite extensive. A suggestion, the source of which we cannot at present trace, for a different application of electricity in ventilation appears to have in it a germ of practical usefulness. The plan is to place resistance coils in the lower parts of ventilating flues, and to pass an electric current through them. The resistance of the coils will heat them, and, in turn, they will heat air in the bottom of the flue and thus produce an upward draft. Of course, this would be too expensive for purposes of general ventilation; but it could probably be made effective for water-closet ventilation in buildings lighted by electricity, thus supplanting gas burners now used for similar purposes. There would be no dripping and running down of condensed water in the flues, as now sometimes occurs when gas burners are used in them for creating draft; and no personal attention would be required, as when an electric fan blower is employed.

A Hot Blast.

Odd things happen, and this experience of an old reader who writes for the first time may interest the boys.

The room was only a small one, yet it could not be heated. An 8-inch hot-air pipe from the furnace had failed, and the same result had attended the use of a 9, 10 and 12 inch pipe, when the old gentleman, who was rather irascible, invited the boss to stop his idiots from coming any more to tear up his house. He said he would show us how to heat that room with a certainty that defied failure and with the furnace just as it was. He had been told that it was impossible to get hot air into the room if the other air could not get out, but he said he did not propose to have a breeze of cold air coming in all around the doors and windows to irritate him just to please a cuss of a heater man, so all the doors and windows were as air tight as thick felt could make them. There was no chimney in the room where a ventilating register could have been placed, even if he would have permitted it, for when it was suggested he stated he did not buy coal to heat air to be wasted going up a chimney to heat the stars, and that ventilation was only a scheme to give lazy chaps a job of figuring money out of other people's pockets. We went by his house every day, and after about a week could see him in his wrapper reading in this little room, which he used for a den, and he seemed perfectly comfortable no matter how cold it was. This excited curiosity beyond control, and the boss asked him to show him how he overcame the difficulty. He did not say a word, but took him into the cellar and showed him a small blower hitched on to the hot-air pipe, then took him into the room and showed him a large wheel with a crank to turn it and a belt connecting with a pulley on the blower. He laid his thermometer on the register and in a few minutes pointed to the temperature registered, then set a chair over the register, tied a handkerchief to it and turned the wheel a few times, blowing the handkerchief violently about and raising the temperature as registered by the thermometer. He motioned the boss to feel his muscle, patted his stomach, hung his coat on the rack, said something about exercise, digestion and warmth, and then invited the boss to leave and reflect on his inability to solve a heating problem that was so simple.

The Furnace.

BY TINK.

Furnace heating, though old, is living yet,
And 'tis many a year since the first one was set.
Through mistakes and queer notions its long life has run,
Yet promises fair to continue right on;
Quite holding its own with many a scheme,
Such as heating with gas, hot water and steam,
And pipes in the streets, through which heat may pass
And go through a meter tremendously fast.
'Tis a wonder it lives in these fast, later days,
When steam, hot water and other new ways
Are pitted against it by men who deride
Its old-fashioned features; with arrogant pride
Praise their new systems quite up to the skies,
And tell what *moist* air from their heaters arise.
It sets me to thinking, and the longer I do,
I wonder greatly why it is true
That in old age, prolonged to such length,
It continues to have such remarkable strength,
Increasing with years, to the dreadful dismay
Of my hot-water friend just over the way.
So I take extra pains satisfaction to give,
That my old friend, the furnace, may prosper and live.
And I tell all men that give me the chance,
That are they but willing to go half the expense
That hot-water plants are well-known to cost,
Not beat me down, and let me be the boss,
I will warm their house perfect for many a day
With a good hot-air furnace in the old fashioned way.

Spiral Coil of Pipe 530 Feet Long.

An unusual job in pipe bending has just been finished by the Brooklyn Tube Bending Company of 75 York street, Brooklyn, N. Y. The pipe is 1-inch galvanized iron and is bent in the form of a flat spiral, 2 feet in diameter at the center and 17 feet extreme diameter, there being 17 turns 4 inches apart. The lengths of pipes are 18 feet long and are united by right and left hand threaded couplings. The coils are kept flat and in position by 32 radially arranged iron straps, placed in pairs, one each side of the coil and bolted together. The pipe was bent cold by a machine arranged somewhat like the ordinary straightening machine. It is first forced through a cylinder of the same diameter as its outside and then passes between two semicircular guide rolls, also of the same diameter. These guide rolls can be set so as to produce any desired degree of curvature in the pipe passing between them. There is no flattening of the pipe, the true circular section being truly maintained. Under a water test of 120 pounds, although the contract only called for 50 pounds, there was no sign of leakage.

Some time since the Department of Public Works asked for bids for an engine for the new high pressure pumping station to be built at 181st street and the Harlem River, New York. Six bids were received, the aggregate sums for furnishing the engines, pumps and other appurtenances ranging from $180,000 to more than $300,000. In each case the bidder was desirous of contracting for machinery exclusively of his own design. It was decided, therefore, to reject all bids received, and to prepare plans and designs for the engine wanted and readvertise for bids. The total estimated cost of the new pumping station and engine is $850,000.

WORLD'S FAIR NOTES.

In Favor of Sunday Opening.

Members of the Chicago World's Fair Directory passed a resolution on the 12th inst. that the World's Fair should be open Sundays on and after May 21. They took this action upon the recommendation of Director Edwin Walker, the leading legal adviser of the board. After many hours of thought Mr. Walker, in consultation with Lyman J. Gage, Henry B. Stone and others, came to the conclusion that Congress had no authority over anything other than the exhibits, and that the directory was free to act in accordance with the terms of the resolution which Mr. Walker presented. His resolution does not propose to open the exhibit buildings, the great structures in which the products of all countries are housed, but merely the grounds about them—the Plaisance and the State and Foreign buildings—providing those in control of them so elect.

Inasmuch as the big exhibit buildings may not be entered by the visitors, the directory proposes that a charge of but 25 cents be made to enter the grounds Sundays. The action of the directory was taken in accordance with what is believed to be public sentiment.

Members of the National World's Fair Commission are disposed to resent the assumed right of the local board to open the gates, even if the exhibit buildings remain closed. They have declared that the directory could not, without the sanction of the commission, put such a resolution into operation, and they have previously threatened that legal proceedings would be instituted if their concurrence was not secured before Sunday opening in any form was attempted.

Foreign Exhibitors Object to Single Judges.

Commissioners representing Austria, Belgium, France, Germany, Great Britain, Italy and Russia have addressed the following protest to the National Commission against single judges:

We believe it would be far more satisfactory if the jury system which has been elaborated at the various great exhibitions of the world could be adopted, a system, that is to say, under which the awards are made by juries of moderate size, representing a certain number of groups, the decision of these juries being subject to revision by a jury of each department, and if necessary by a single superior jury, on which foreign commissions should be duly represented.

We think that the opinion of a single expert would be less satisfactory to an exhibitor than the opinion of a number of such experts acting as a jury. We think that duly qualified experts would shrink from the responsibility of making individual reports.

We believe it would be impossible to examine during the time of the exposition all the individual exhibits in the way we understand it is proposed, and we consider that proper weight should be attached to the reputation of the exhibitor, to the excellence of his manufactures, and not solely to the merit of the special articles which he may have produced solely for the purpose of exhibition.

With regard to the proposal that the awards should be of a single class, we understand that this has been definitely decided by the National Commission, and we do not propose formally to raise any objections, but we consider that the idea of graduated awards is preferable, and we would suggest that at all events some distinction may be made on the diplomas as to the degree of merit appertaining to each exhibitor's production.

We would further impress on the National Commission the necessity of definitely informing foreign commissioners of the number of judges allowed to each country, and of the classes in which they should be appointed, and the proportion which foreign judges would bear to American judges; that a definite date should be fixed on which the jurors should commence their work, and that no alteration should be made in this date; also that a definite date should be fixed on which the jury of revision should receive the reports of juries of first instance.

In making these suggestions we have endeavored to formulate what we consider to be the most moderate concessions which we believe foreign commissions have a right to demand on behalf of the interests of the countries they represent, and we feel that unless these concessions are made foreign commissioners must reserve to themselves the right of declining to take part in the work of the awards, and, if necessary, of placing the exhibits of their respective countries *hors concours* and withdrawing them from the consideration of the judges.

The difficulty about the system of making awards at the fair arises from the fact that even those who prepared the plan do not know exactly what it means. John Boyd Thacher of New York is acting chairman of the committee. Mr. Thacher wanted to ignore all precedents, do away with juries of awards, and have a single judge examine the articles offered for competition in a certain group. He worked on that scheme nearly two years. Some months ago the Board of Control took up Mr. Thacher's plan and modified it. The Board of Control recognized the one-judge system to the extent of ordering that one judge should examine the articles and write the reports, which were then to be signed by other members of the jury.

"It's the single-judge plan," Mr. Thacher gleefully exclaimed, after his long fight with the Board of Control.

"It's the old jury system, pure and simple," said members of the Board of Control, and both quit the contest feeling that a great victory had been won.

It may be that the plan indorsed by the Board of Control is none other than the old-fashioned jury system, but exhibitors did not so construe it, and complaints have been pouring in on Director-General Davis for months. Exhibitors criticised the one-judge plan no less severely than they did the long delay in naming foreign judges who were to pass upon exhibits in the international work.

The matter will again be considered by the National Commission, in view of the decided position taken by the foreign exhibitors.

Demand for Engineering Tests.

Dissatisfaction is expressed by engineers, by manufacturers of boilers, engines, motors and railway appliances and by fuel companies with the methods of making awards at the World's Fair. It is understood that no sort of test is to be made of any engine, motor or fuel or mechanical device whatever. It is greatly to be deplored, these engineers say, that the exposition authorities have seen fit to neglect such an important matter. Here, they say, is an opportunity such as never before existed for the world to acquire a fund of information valuable beyond all computation to engineers and to manufacturers. Every type of engine, steam generator, gas and other motor; all methods for the transmission of power by compressed air, electricity, wire rope; all sorts of carrying machinery and numberless other mechanical devices are here gathered together ready to have their comparative merits shown, and the opportunity is to be passed by. It is understood that no provision has been make for comprehensive scientific tests as suggested by the American Society of Mechanical Engineers. It is urged that not only practicing engineers but business men desiring to engage in some line of manufacturing could refer to the reports made and have an actual, unprejudiced account of the performance of any engine or machine in which they might be interested, instead of being forced to rely on the assertions of manufacturing agents.

This would not necessitate any competition, the engineers say. All tests of each class of exhibits could be made on the same line and the results published by the World's Fair authorities. They agree that even if Mr. Thacher would carry out his single-judge idea and provide means of making tests it would be a big thing. It would be better for all concerned, they say, to have fewer judges and spend some of the money thus saved in making the tests.

As for the manufacturers who have exhibits at Jackson Park, they seem to have taken it so entirely as a matter of course that tests were to be made that most of them expressed great surprise when it was intimated to them that such was not the case. Had they known, many of them say, that no tests were to be made they would not have spent so much money in making exhibits. Some go still further and declare they would have made no exhibits at all. In brief, it would seem that all concerned are extremely anxious that tests be made.

In December, 1892, a committee appointed for the purpose by the American Society of Mechanical Engineers, at the request of the Committee on Awards of the World's Columbian Exposition, presented a report on methods for physical and mechanical tests of steam engines and other machines. After dwelling upon the great opportunities afforded by international expositions to keep pace with the developments of other nations in the various departments of science and art and for careful tests of the relative merits of the various products, manufactures, machines and methods developed under different conditions in various parts of the world, the committee recommended a most elaborate series of tests, going into great detail for the guidance of the National Commission. Although submitted in due form and in good season, is is said, this report was practically ignored by the Committee on Awards. Its suggestions have not been acted upon. Whatever merits the exhibits of engines, boilers and motors may possess will from present indications not be disclosed at the fair. All exhibits of this class will be there exclusively on appearances.

State Commissioners Aggrieved.

States rights at the fair was discussed at a recent meeting of the Executive Committee of the National Organization of State World's Fair Officials. The Executive Committee consists of E. C. Hovey of Massachussetts, chairman; A. B. Farquhar of Pennsylvania; B. F. Havens of Indiana; Donald McNaughton of New York; J. D. Apperson of Iowa; C. P. Mattocks of Maine; J. C. Wyman of Rhode Island, and J. G. Gwynn of Missouri.

For several months the State executive officers have felt dissatisfied at the way things are running at Jackson Park. It is said that they have not been treated with dignity at the hands of the exposition authorities, and that not only has no official ceremony been used in dealing with them, but they have received no recognition upon public occasions, and beyond being held re-

aponsible for their States' exhibits being ready on time they have been left to shift for themselves.

This has gone on for some time, according to some of the commissioners, and the Executive Committee was appointed to see that hereafter the State officials received the courtesies they claim they are entitled to. One of the Executive Committee says :

"We want our position at the exposition defined. Our State governments have sent us here to represent the functions of the different States at the fair. We have been treated with scant courtesy, and have never been asked to participate in any of the public functions of the fair. Representing as we do the great commonwealths of the United States, it seems hardly right that we have never been asked to meet officially any of the representatives of foreign powers. Our position seems to be only that of overseers of exhibits. We were sent on here by our States to direct foreign attention to our different sections. As yet I have to see the opportunity that any of us has had of meeting any of the foreign commissioners other than in a purely personal matter."

Germany's Great Display.

Germany takes a position of such prominence in all departments of the fair that it almost looks like a German exposition. Germany's exhibits are the pride of all who either claim allegience to that country or are of German descent. The German Building, overlooking Lake Michigan, is the showiest of all the foreign buildings. The exhibit made in Manufactures Building is the furthest advanced of the exhibits of foreign governments in that building with the possible exception of Great Britain. In every building on the grounds the German exhibits are far along, and there are some critics who claim for many of these greater excellence than that possessed by other exhibits.

The great feature of the exhibit in Manufactures Building is the open courtyard fronting on Columbia avenue, where is to be shown the handiwork of the German gold and silver smiths and the porcelain art work, in which the artists of the German Empire excel the workmen of all other countries. There is a space of 161 feet, separated from the broad passageway by a fence of wrought iron, with three gates also in wrought iron, which combine massiveness with artistic workmanship. The fence is in itself one of the most interesting displays not only of the German exhibit, but of the entire exposition.

As a background to the gold and silver exhibit is built a portico with saracen pillars of porcelain and having for a centerpiece a huge painting on porcelain tiles, the work of Prof. A. Kips of Berlin. This is flanked on either side by an allegorical painting on porcelain, and to the north and south of this are alcove rooms, a part of the whole which ends in curved walls which in turn are joined to iron gates.

Armbruster Bros. of Frankfort-on-the-Main furnish for the exhibit the beautiful wrought-iron fence which separates this section of the exhibit from Columbia avenue. The style of the work is rococo and the central one of the three gates is said to be the largest piece of wrought-iron art work ever made. It stands 40 feet high and is 22 feet in width, and the gates alone weigh 18 tons exclusive of the elaborate posts and surmounting top piece. The side gates are 30 feet high and 15 feet wide, and each pair weighs 13 tons. The iron was hammered and wrought from crude bars entirely by hand work. The fence complete represents the work of 150 of the firm's most skilled workmen for a total period of almost six months. Fruit and flowers and delicate leaves have been hammered from the iron until they look to be the work of a skillful goldsmith, instead of the brawny wielders of sledge hammers over huge anvils. The central gate is the principal feature of this exhibit. Huge bars extend from the top to the bottom, filled in between with delicate tracery work, and the top and bottom are each marked by molding in keeping with the whole. Towering high above the top piece is a basket of flowers, hammered out of iron, and looking as life-like, save for the color, as would a basket of wax fruit or flowers. The total length of the fence is 161 feet. After its completion it was set up both in Frankfort and Berlin and the news of its excellence brought thousands to view it. The Emperor himself paid it a visit and expressed his admiration of its workmanship in unmeasured terms of praise. It is probable that the fence will remain in America at the close of the exposition.

Baden makes an exhibit at the north end of the inclosure. There are three artistic iron gates, which serve as a background, the central one of which stands 20 feet high and has beneath its ornamental top piece the word "Baden," wrought in iron. The work of the jewelers of Baden will be shown in cases directly in front of this. These gates are the work of Bieler of Offenburg, Baden. The Bavarian countries have contributed three more ornamental wrought-iron gates for the south end of the inclosure.

Passing around the north end of this block and walking south one comes to some exhibits of wonderful interest and beauty. The first is a collection of old-fashioned German wood stoves. This strange article is made of earthenware or porcelain, as the case may be. Each stove is 10 or 15 feet high, with folding doors to the grate, and decorated in the highest style of art. One can only compare it to a church altar in pottery or porcelain. The style of the room is rococo and renaissance. Next comes an extensive exhibit of cooking ranges by H. Koloseus of Aschaffenburg. They are 6 x 13 feet in size, faced all around with beautiful tiling and mounted with polished steel and brass.

The third block of the German exhibit contains more splendid exhibits than both of the others put together. The first of these exhibits is that of the great cutler, J. A. Henckel, at Solingen. Forty feet of upright showcases, with plate-glass doors, are filled with his table, pocket and surgical cutlery. Lying down in the front of this show case is a magnificent pair of lady's scissors. The blades reflect everything about them like mirrors, and the handles appear to be of gold exquisitely chased. Crowds of ladies bend over them, and gaze wistfully at them; and yet they will probably never find a purchaser, as they are 6 feet long and weigh 200 pounds. Other familiar articles of cutlery in the same neighborhood are on the same Brobdingnaggian scale. There are carving knives and forks, of perfect finish in every way, that are 4 feet long, and that would be a good load for a man; and numerous butchers' knives and kitchen knives are just as large. But all of them are as elegant in every respect as those of smaller size.

The next exhibit is equally interesting for its intrinsic merit and on account of the exhibiter, Prince Stolberg, who is one of the hunting associates and boon companions of the German Emperor. The exhibit consists of decorative iron work from the Prince's immense works at Ilsenburg, in the Hartz Mountains. The articles are antique shields, breast plates, helmets, swords, battle axes and spears, and then a line of more peaceable articles, such as tables, screens and cigar presses.

The next attraction is a needle exhibit by Funker Bros. of Siehen, mainly noticeable for a large picture of a steamer on a rough sea, all done in needles, which are skillfully made to resemble the sheen of the water. There is a rare exhibit of hammered copper goods by Peter Seitz of Munich, consisting of vases, chandeliers, lanterns, crucifixes, champagne coolers, and what not. Immense vases, 4 feet high and 3 feet wide, graceful in shape and elaborately chased and decorated, are shown, which have been hammered out of a single piece of copper at a cost of $500. The next exhibit is that of the Gaggenau Iron Works, the specialty of which is a patent process for a permanent and artistic enameling of iron. The articles exhibited include vases, console tables, card tables, decorative shields, flower stands, alcohol lamps, match safes, inkstands and a whole line of kitchen and dining-room ware. These articles are made of iron, and exquisitely painted so as to resemble the finest earthenware. So handsome are some of the designs, and so elegant the workmanship, that one forgets that it is ironware. At the immense works of the company, of which a large painting is displayed, 1200 workmen are employed, while the work is protected by at least 100 patents.

The last booth on the east side of the block is that of Armbruster Bros. of Frankfort-on-the-Main, the manufacturers of the great triple gates of the German exhibit on Columbia avenue. In the Armbruster booth one will see smaller articles which display even greater skill. These articles are candelabra, chandeliers, candlesticks, andirons, shields, railings, door trimmings, flower stands, signs, German creats, screens, brackets, picture frames, jewelry boxes, yes, and vines and flowers, all hammered by hand out of iron.

In all exhibits are made by more than 3000 German firms and individuals. These include the exhibits in the various buildings, but the greater part of the number are to be found in the German exhibit in Manufactures Building.

The Belgian Exhibit.

The little kingdom of Belgium has a very fine exhibit in Manufactures Building, conspicuous for daintiness of design and fine workmanship. In a few lines something really ambitious has been attempted, as for instance in plate glass A plate 18 x 12 feet is shown, which is an inch thick, without a flaw, and so clear that it is almost invisible. In hammered iron work the Belgians have not exerted themselves to make anything ponderous, but they have produced a few specimens of small size that are unequaled for intricacy and delicacy. One reproduces the branch of a tree, with flowers, birds and leaves complete in the smallest detail.

American Exhibits.

While there is a very great deal to be seen in every department, and visitors can now feel repaid for taking the trouble to make a trip to the fair, there

is hardly a section in which belated exhibitors are not seen hard at work completing their booths or installing their goods. So incomplete are the various departments that it seems invidious to enter upon the work of describing what has been done and necessarily omitting exhibits which will in a short time be fully as attractive as any. Another week or two will, however, make a great difference in most of the buildings.

American Tin-Plate Exhibit.

For a time the outlook for an exhibit of American tin plate was decidedly dubious. This would have been a serious omission, reflecting severely on American tin-plate makers. Through the energy of H T. Duff of Wallace, Banfield & Co., Irondale, Ohio, the gap is being filled A large portion of the south gallery of the Mines and Mining Building was secured, and workmen are now busy in the erection of an ornamental pavilion to be constructed wholly of American tin plate. In it will be shown specimens of the metal in its various stages, beginning with the crude materials and crowning the whole with the best specimens of the American tin-plate maker's art. The exhibit will be known as that of the Associated Tin Plate Manufacturers of the United States.

Singer, Nimick & Co.'s Unique Exhibit.

A novel feature will be introduced in the exhibit of Singer, Nimick & Co. of Pittsburgh in the Mines and Mining Building. While they will show numerous samples of their tool steel, circular saw blanks, plow and cultivator steel, spring steel, &c., all arranged most tastefully, they have added to these an exhibit of a very wide range of finished products made from their steel, contributed by their customers. These are displayed in glass cases, and comprise such articles as bicycle drop forgings, sewing machine parts, watch springs, mechanics' fine tools, files, deep drawn cups and sockets for various purposes, table ware in its various stages from the crude steel to the silver-plated product, &c. This exhibit is intended to show the requirements which must be met by steel makers in the production of steel for a great variety of special purposes.

In the Electrical Building.

The Western Electric Company of Chicago are preparing an exhibit which aims to reproduce the very lightning of the heavens. A row of incandescent lights has been attached to a zigzag frame work about 60 feet in length, suspended from the ceiling, and through this will be sent intermittently a current of electricity. At the end it will be absorbed by a ball of incandescent lights with colored bulbs, the effect being that of a ball of fire dropping from an electric flash. There are four of these lightning lines of light radiating from a common center, the top of a 40-foot pillar. Around this pillar, 2 feet in diameter, are twined strings of incandescent bulbs of red, white and blue, 2000 in number. The pillar itself will be coated with bits of broken glass, so that light will be reflected in dazzling brilliancy in every direction. These lights will not all be kept burning at the same time. By an ingenious mechanism the current is made to pass from one row to another, beginning at the base of the column, and the effect will be a creeping upward of the three colors in succession until they reach the top, when they will shoot out along the zigzag lines like a lightning flash, to be absorbed by the balls at the ends. These balls will have the three national colors, but there will be a magical intermingling of light, as they will continually revolve at the rate of 60 to 80 revolutions a minute.

The same company have reproduced for their pavilion an ancient Egyptian temple, the ceilings of which are covered with multi-colored glass, representing jewels, above which will be placed moving electric lights, the effect being a constant succession of colors of great brilliancy. The pillars of the temple are made of glass and within the hollow center will again be placed electric lights, producing the same effect. The Egyptian eagle above the open doors, which in daylight looks like a surface picture, is also of glass, behind which there will be kept burning electric lights. The company's sign is also of glass, but so constructed that, with moving lights behind it, it will seem to flash forth the light of the diamond, sapphire and other precious stones.

Department of Machinery.

Workmen are still in possession of Machinery Hall, and represent almost as large a number as the visitors who are roaming around the huge building, watching the work and inspecting such of the exhibits as are completed. Few persons can have an adequate conception of the difficulties experienced by the management in the performance of such work as requires the employment of skilled labor. The exceptionally large force required renders the proportion of really competent workmen so small as to constitute them the exception rather than the rule, notwithstanding that every effort is made to secure all who are available. As a natural result of this condition of affairs, not only does the work progress slowly, but through the ignorance and carelessness of the incompetent element, much of it is found upon completion to be so imperfect as to require more time to correct the faults than should have been necessary for the entire work under ordinary circumstances. Outside of the work pertaining strictly to the installation of exhibits—which is, of course, done by the exhibitors themselves, and for which they are solely responsible—the various features of the general equipment of the buildings are progressing rapidly toward completion. There are now but few instances, if any, in which delay to exhibitors is occasioned from want of necessary connections with steam, water, compressed air, or oil, service pipes; and the distribution systems for electric currents, for lighting and power transmission, are being completed as rapidly as the installation of the exhibited generators and their motive power will allow. The capacity of the steam, water and fuel-oil supply is far in excess of the present requirements, and all work pertaining thereto will be completed long in advance of the exhibits dependent upon it. While up to the present time the responsibility for delay has undoubtedly, been divided between the exposition management and the exhibitors, it may now fairly be said to devolve almost entirely upon the tardy ones of the latter class; and to their efforts we must now look for the completion of one of the most important of the many departments of this great exposition. With reference to the power plant, the progress has not been as rapid during the past two weeks as might have been fairly expected Though, in some few instances, the work has been completed upon both engines and the dynamos and generators which they are to drive, their operation is delayed for want of the belting. As many of these latter are of 72 inches width, the work of putting on and splicing requires considerable time. None of the large engines are in operation except for one hour or so occasionally, though several are entirely ready for continuous service.

The Allis quadruple expansion is waiting for the 72 inch belt which will connect it with the second of the Westinghouse dynamos. The Fraser & Chalmers and the Buckeye 1000 horsepower triple expansion engines, for similar duty, are waiting for the same reason, as is also the Atlas 1000 horsepower twin tandem compound. Most of the isolated engines scattered throughout the main building and annex are in operation, driving the line shafting. The paper mill of the paper trade exhibit has made wonderfully rapid progress, though judging from its magnitude and the amount of work still to be done, it will require several weeks before it can be ready for operation. Outside of the power plant, nearly all of the completed exhibits are confined to the annex, although there are a few notable exceptions in the main building. The hydraulic basin still presents the appearance of a depressed roller-skating rink—the water not yet having been admitted—though this is due to the fact that the pumping machinery to be supplied by it is composed of numerous exhibits, but few of which are completed. Of machinery in operation the most conspicuous is that of the textile class, there being a large number of looms busily engaged in weaving fabrics containing various souvenir patterns—the latter, of course, being offered for sale, and finding ready purchasers in such visitors as will have but limited opportunity for visiting the fair. A few of the stamping press exhibits have machines running on souvenirs, consisting mostly of hardwood medallions embossed in some memorial design. The classes of wood-working machinery and machine tools are well represented by completed exhibits, so far as the actual placing of machines and clearing up of spaces may be so considered, though but few are yet in operation. Notwithstanding the fact that the limit of the time in which delayed exhibits were to have been admitted to the buildings, there is still a very large amount of unoccupied space. Also, there are many spaces in which the material still remains untouched in the packing cases, apparently totally neglected. Throughout the entire building the floor is more or less obstructed by scaffolding and material for the construction of platforms and pavilions, arrangement of exhibits, and miscellaneous rubbish from empty packing cases, &c. While to those who will have the opportunity of frequent visits there is sufficient to occupy a full day's attention, and they may see it later in its entirety; for such as desire to see it only as a completed exhibition it will be well to defer their visits for the present.

The Colorado River Irrigation Company have just been incorporated under the laws of Colorado, with an authorized capital of $7,500,000. Several New York and Western capitalists are interested. The plan is to excavate a canal 150 feet wide and 10 deep, and the tract to be irrigated comprises 3,000,000 acres, of which one-third are in lower California.

ROOFING AND CORNICE.

New Designs of Terra Cotta Roofing Tile.

A form of roof covering possessing many features concerning which architects, carpenters, contractors, and, in fact, all having to do with building construction cannot fail to be deeply interested is now being introduced to the trade by the Celadon Terra Cotta Company, Limited, of Alfred Center, N. Y. The covering consists of vitrified terra strong clay, which is manipulated in much the same manner as pottery is manufactured. The clay is subjected to great pressure between bronze dies, which give the pattern desired, after which the tiles are dried on plaster forms and baked in seggers. The tiles when completed are dense, strong and highly non absorbent. In color they vary from different shades of buff and red to a dark chocolate. The process of manufacture employed, howing to the roof, it is claimed, "that mobility of expression which is the charm of nature." The company make five sizes of the Conosera tile, with which, it is stated, can be covered in a superior manner any size or proportion of cones or towers. One form of this tile is represented in Fig. 5 of the illustrations. The company also supply glass tile, interlocking with those made of terra cotta and intended for skylights. Most of the designs and combinations pro-

NEW DESIGNS OF TERRA COTTA ROOFING TILE.

cotta roofing tiles made by a special process from a peculiar clay, which, when laid in position, give effects both artistic and highly ornamental. These results are possible by reason of the special construction of the tiles and the almost limitless combinations in which they may be employed. These tiles have a heavy and substantial appearance, and yet they weigh much less per square, we are informed, than what are often designated as Spanish tile, and are sufficiently strong to be walked upon. The illustrations which we have pleasure in presenting to our readers show some of the various patterns of tile made by the company and one of the innumerable combinations in which the tile can be used. The material employed is a superior quality of tough, ever, is such that they can be glazed any color required. One of the strong features of the tile here illustrated is a deep flange which permits of the interlocking of different patterns, thus enabling the use of any number of styles desired in a single roof. The tile are also adapted for siding as well as roofing, and afford the opportunity for new and novel effects in exterior decoration. The manufacturers state that the interlocking character of the tile enables a wind proof and storm tight roof to be secured under circumstances where pan tiles have proven unsatisfactory. One of the novel effects claimed for these tiles is the seeming change in form presented by them under different conditions of light and viewed from varying standpoints, given to the roof, it is claimed, "that mobility of expression which is the charm of nature." The company make five sizes of the Conosera tile, with which, it is stated, can be covered in a superior manner any size or proportion of cones or towers. One form of this tile is represented in Fig. 5 of the illustrations. The company also supply glass tile, interlocking with those made of terra cotta and intended for skylights. Most of the designs and combinations produced by this company are new and fully covered by letters patent. The company are represented in New York City by E. L. Hyde of 30 Cortlandt street.

FLASHINGS.

The Slatington-Bangor Slate Syndicate of Slatington, Pa., have just issued from the press a neat little pamphlet of a size convenient to carry in the pocket and entitled, "Slate Manual and Descriptive Price-List." Within its covers a great deal of information of interest and value to the slate roofer is presented, prominent among which may be noted sizes and prices of various kinds of roofing slate and rules for measuring slate roofing.

"Decorative Metal Ceilings" is the title of a very neat pamphlet which reaches us from Lyles & Mills of 231 William street, New York City. Numerous designs of paneled and embossed steel ceilings are presented, together with illustrations of moldings, cornices, &c. Several illustrations are also given of buildings in which the company have introduced their work.

The adoption by the Chinese of galvanized iron for roofing, to which allusion was made recently, is reported to be growing rapidly. The advantages of metallic roofing, as demonstrated in the houses of Western residents in China, seem to have at last struck these most conservative of people, and latest advices from China say that the transformation, which only commenced lately, is very quickly becoming general.

The Crown Ventilator Company, 356 Fulton street, Brooklyn, are putting out a new chimney cap which can be nested for shipping or sent flat, and any tinsmith can readily put it together.

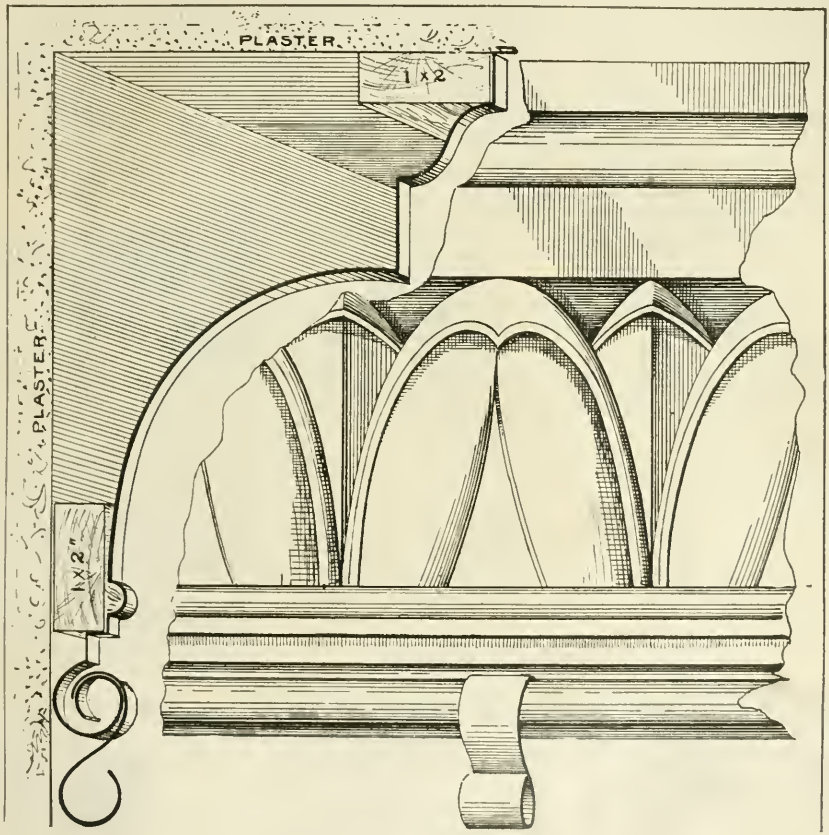
A good fire-proof roofing, and one unaffected by the sun's rays, not melting or running, is, says the London *Plumber and Decorator*, obtained by adding burned lime (not slaked) to coal tar. Boil together in the proportion of 15 pounds of lime to 100 pounds of tar. The lime must be pulverized, and to avoid the tar boiling over, stir the lime slowly in the boiling tar. The mixture must be applied while hot. It would be interesting to know if the admixture of lime counteracts the corrosive action generally complained of when coal tar is used on metal roofs.

Bowers, Galpin & Co. of Binghamton, N. Y., manufacturers of gutters, gutter pipe, roofing, &c., are about to build a new factory. The structure will be 600 x 150 feet, one story in hight.

The Illinois Roofing and Supply Company, 203 Lake street, Chicago, have issued a very handsome 100-page catalogue of their specialties. It is bound in a neat paper cover with an embossed gilt title. The contents cover a full description of the Perfection lock seam roofing, giving directions for laying it; Climax cap seam roofing, pressed standing seam roofing, semi-steel V crimp roofing, beaded siding and ceiling, ornamental patterns of siding and ceiling, steel clapboards, Imperial pressed steel brick, rock-face brick siding, pressed corrugated iron, curved iron, Cushman metallic shingles, Imperial 2 and 3 ply prepared roofing, corrugated iron doors and shutters, ready-mixed paints, &c. Part second of this catalogue deals with tinners' supplies in general, as, for instance, eave troughs, miters, roof gutters, hangers, corrugated conductor pipe, round pipe, spiral lock-seam pipe, adjustable elbows, one-piece elbows, conductor hooks, chimney tops, ventilators, ridging, crestings, spun balls, galvanized iron, roofing tin, sheet copper, tinners' tools, &c. The articles are all priced, and a discount sheet accompanies the catalogue, making special discounts on sundry goods. The entire arrangement shows great care, and the catalogue cannot fail to be appreciated by the trade.

Metal Cornice and Picture Molding.

Fred. F. Bischoff & Co., 24 and 26 West Lake street, Chicago, have brought out a new design of metal cornice, which is herewith illustrated. In this design the picture molding is combined with the cornice, thus saving the extra expense of the molding, as well as making a more complete finish to the cornice. The illustration shows a profile or sectional view, as well as a front view. This cornice is not only pleasing in relief but is stated to be cheaper than plaster or other material, and will also serve a useful purpose in hiding cracks in ceilings and walls to which new buildings are subject. The steel cornice can be used in connection with plaster or steel ceilings.

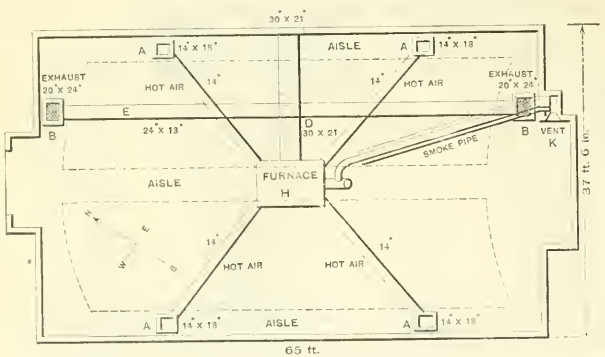


Metal Cornice and Picture Molding.

THE LETTER BOX.

Warming a Church.

From J. J. WILSON, *Troy, N. Y.*—I read with much interest in your issue of April 15 your answer to "W. D.," Oxford, N. S., in regard to warming a church. The suggestions you make and the advice given are good. There is no doubt that a number of your readers, notably the younger portion, would like to have a more detailed explanation of this work, especially as it should be done according to modern practice and using the existing conditions of building. For the special benefit of your apprentice readers I have made the inclosed plans and details. If we expect to elevate our trade as an art we must seek to more fully educate our apprentices. The secret of the elevation and high standard maintained in the plumbing trade are due in a great measure to the manifest interest and supervision given the young seekers after knowledge by those qualified to do so. I know of a large plumbing shop, not many miles from Pittsburgh, where each journeyman and master workman in the tin and sheet-iron trade would resolve to furnish his trade journal with one contribution each three months—that is, four contributions per year—on some class of work in the line he is most familiar with. I am sure all would be agreeably surprised at the beneficial effects in elevating the standard of work and intelligence among the embryo tinners. In regard to warming a church, not having the elevation to determine exact cubic contents, I have assumed contents quoted by you, viz., 36,000 cubic feet. I have located furnace in center of church and connected thereto four 14-inch warm-air pipes, each 18 feet long, and connected at floor line with four 14 x 18 inch register boxes and floor borders. The area of 14-inch pipe is $154 \times 4 = 616$ square inches, and with an assumed velocity of flow through warm-air pipes of 5 feet per second per each square foot of space, allowing for friction in flow, turns, &c., the area of warm-air pipes is sufficient to furnish



Warming a Church.—Fig. 1.—Plan of Rearranged Pipes.

problems in plumbing work, contained in *The Metal Worker*, are placed upon a blackboard; the apprentices, with chalk in hand, are brought forward and catechised until the problem is fully solved and the work intelligently comprehended. As the master plumber said, "Since I commenced this routine, which rarely takes over half an hour per week, I have put dollars in my pocket. I find that my young men take more interest in my business, are

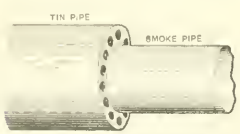


Fig. 2.—Smoke-Pipe Casing.

anxious to become first-class workmen, and they all endeavor to reason out and perform practically such duties pertaining to the trade as may be intrusted to them." Here is a pointer for some of the progressive master tinners. If a church with two changes of air per hour, or over 72,000 cubic feet of warm air per hour, the total area of warm-air pipes being 4^5_8 square feet. The exhaust registers at each end of the church are so located as to be entirely out of the way in entering the vestibule, aisles or chancel, and also admit of a straight duct to cold-air box. The two exhaust ducts are each 24 x 13 inches, and have a combined area of 624 square inches, equal to the combined area of the four 14-inch warm-air pipes. The reason such an area is used in exhausts is because the inside air is of a much warmer temperature than the outside air, and, hence, has not the expansive qualities of air at a lower temperature. The exhaust ducts are connected to the cold-air box by a main trunk 24 x 26 inches, which is qual to the combined area of the two exhaust ducts. The cold air is brought from a north by east point and is $30 \times 14 = 420$ square inches, being a little over two-thirds the area of warm-air pipes, and where the main trunk of the two exhausts join it an enlargement is made to $30 \times 21 = 630$ square inches, so that this part of the duct will be able to carry off full capacity of the two exhaust ducts. A hinge damper is also located at this point, so that either cold-air box or exhaust ducts can be turned on independent of each other, or part of flow to furnace taken from each. The operation is intended to be as follows—viz.: Before church assembles the exhausts are open to the furnace,

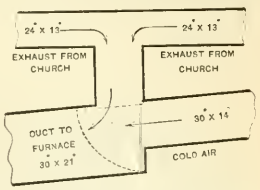

Fig. 3.—Mode of Connecting Exhaust and Air Supply.

the cold-air box is closed, the air from the church then passes to the furnace, is heated and delivered in the church again. As soon as church is ready to be occupied, the damper in cold-air box is reversed, exhausts are closed, cold-air box opened and air from outside brought to the furnace, heated and delivered through warm-air registers to the church. The smoke pipe is incased in a tin pipe which has a head on the end near the furnace with an opening through which the smoke pipe passes and is perforated so that air can pass between the tin casing and smoke pipe. The air becoming heated, it is delivered into smoke flue; this relieves the air of cellar from becoming excessively heated, and also permits of the ventilating register K being used in smoke flue without affecting the draft of the chimney, as this heated air passing to the flue keeps it warm and accelerates the velocity of air which passes through the vent register. It is understood that this register is not intended to fully ventilate the church, but it causes a movement of air to exhaust from the church, which is highly con-

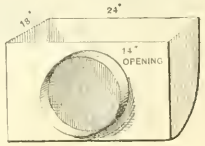

Fig. 4.—Register Box and Collar.

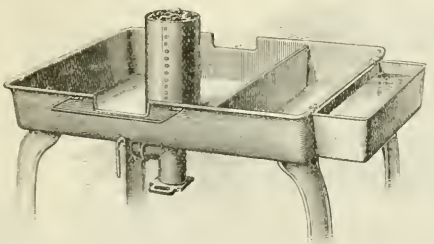
ducive to quick and efficient heating. In regard to details: Fig. 1 is a plan of the church with pipes rearranged. Fig. 2 shows end section of tin pipe, with perforations for air to pass between it and smoke pipe to the smoke flue. Fig. 3 gives side elevation of exhausts, main trunk connection to cold-air box, enlargement of same where the exhausts are connected, and location of hinge damper, to control flow from exhaust duct and cold-air box. Fig. 4, detail of register box to be used, in which by using angle collars in side elbows can be dispensed with, and this style of box allows of increased elevation of warm-air pipes. In churches, especially, provisions

should be made for ventilation by building a proper size vent shaft, with the smoke-pipe exit passing through its center, and while there are some constructions whose architecture compels the placing of the shaft at some remote point of the building, by the judicious locating of a series of exhausts or vents connected to a main trunk or duct, and that in turn connected to shaft, practically successful results can be obtained.

Tinning Copper Wash Boilers.

From J. E. B., *Troy, N. Y.*—I have noted the inquiry of "C. F. T.," about tinning old copper wash boilers, that appeared in *The Metal Worker* of March 18. I have a set of saucepans, jelly molds, &c., owned by the proprietor of the works where I am employed, to retin once in a while, and I thought, perhaps, my method of procedure would interest some of your readers.

When the coppers come to the shop a package of whale bleach (Soapine) comes with them. It is dissolved in a pail of warm water, the helper rolls up his sleeves and gives the coppers a thorough scouring to remove the grease, using as accessories Soapine, a wad of waste, and some fine, sharp sand. The finer the sand the smoother the coppers when finished. In the meantime a forge in the smith shop is made ready for business. A piece of sheet iron is cut and formed into a cylinder 7 inches in diameter, 1 foot deep and placed over the tuyere, all soft coal being removed, as it would blacken the outside of the coppers and make a neat job difficult. A charcoal fire is now made in the cylinder, the general position of the cylinder and fire and general arrangement of forge being shown in the illustration.



Tinning Copper Wash Boilers.—Forge Arranged for Tinning.

The tin is prepared in the following way: About 2 pounds are placed in a hand ladle sufficiently large to hold double the amount and melted. As soon as melted the metal is removed from the fire and kept constantly stirred with a stick of wood shaped like a big wooden spoon until it is all finely pulverized. When properly done it has the appearance of sea sand. The first time it is tried the result may be failure, but very little practice will insure success. The tin is then sifted through fine wire cloth or other suitable material, and what goes through is kept separate from the portion that is sifted out. Muriatic acid saturated with zinc is used for flux. The coppers, previously scoured, are now thoroughly rinsed to remove any sand. They are then wiped dry outside to insure against any tin sticking there, and all are given a coat of acid internally. Those that are to be tinned both inside and out are coated with acid on both sides. When all are coated, the first one is again coated and the sides sprinkled with the finest tin, the bottom with the coarsest. The copper is then held over the fire and the tin on the bottom of the mold melted first, and next the sides. The handle side is then turned down and melted, the copper being revolved as the tin melts until the handle side is again down, which is given an extra heat. The copper is then removed from the fire and the surplus tin shaken out. It is then held, handle side down, and what little tin remains is collected around the rivets and chilled there with a wet wad of waste held outside.

The advantage of this method is that as the acid and tin are affected by heat at about the same time, the advantage of having them both in the right place at the right time is evident; also where coppers are to be tinned both inside and outside, it is indispensable unless a dipping pot is used. Care must be taken not to get the coppers too hot, which is my objection to using sal ammoniac, unless it is dissolved in the acid.

Pump for Driven Well.

From J. W. *Fulton, N. Y.*—In ply to a letter of "H. A. C.," Bainbrrge, N. Y., that appeared in *The Metal Worker* of April 22, concerning driven wells and small pumps connected with $1\frac{1}{4}$-inch pipe, would say that I have had some experience in that line which may interest him. I have driven a well of this kind where I have used $1\frac{1}{4}$-inch pipe with a No. 1 pump with a hoist of nearly 23 feet, and the pump worked so easily that a child could operate it without trouble. I think there must be something wrong at the bottom of the pipe in your correspondent's case. I had to take my pipe out after I had it driven. The difference in soil sometimes makes a difference in the working of the pump. In hard, stony ground the pump will not work as easily as in loamy land.

Boiler Connections.

From MILWAUKEE GAS STOVE COMPANY, *Milwaukee, Wis.*—In your issue of May 6 we note the "sharp criticism" from "S. H. D.," Watkins, N. Y., on the method we advocate of connecting the hot-water circulating pipe to the top of the boiler. The article in question scarcely requires an answer, for the positive injunction, "the hot-water pipe should never be taken from the circulating pipe," is entirely neutralized by the contradictory statement that "there is no objection to connecting the circulating pipe to the top of a boiler if all of the other connections are properly placed." Right here let us advise all plumbers to see that all connections are "properly placed." When this method was first advised we met the same opposition from almost every plumber with whom we came in contact, and to stop useless arguments we settled down to a standing offer to pay the cost of all connections if the results obtained were not as we represented. We have now many converts. Several hundred gas stoves and heaters connected in this manner with tanks from 30 to 200 gallons capacity are under our observation, and we have yet to hear of a single complaint. Coming to the vital question—Will cold water be drawn through the heater instead of hot water from the boiler when the hot-water circulating pipe enters the top hot-water outlet of the boiler? our answer is that this will take place when the laws of nature are reversed and hot water ceases to rise.

Copper Bronze for Tin.

From C. & R., *Portland, Maine.*—We have seen tin tea kettles that were covered with either a bronze or lacquer or solution that made them so closely resemble planished or burnished copper that it required careful inspection to discover that they were not copper. Can you give us the information to enable us to do this work?

Answer.—This result may be accomplished by electro plating, and doubtless that is what our correspondents have seen. Inquiries as to the value, for the purpose mentioned, of the bronzes used on hot-water and steam heating radiators find opinions differing. A quality of bronze specially adapted to this use might, however, be furnished by some manufacturer or importer of bronzes.

Brazing Steel.

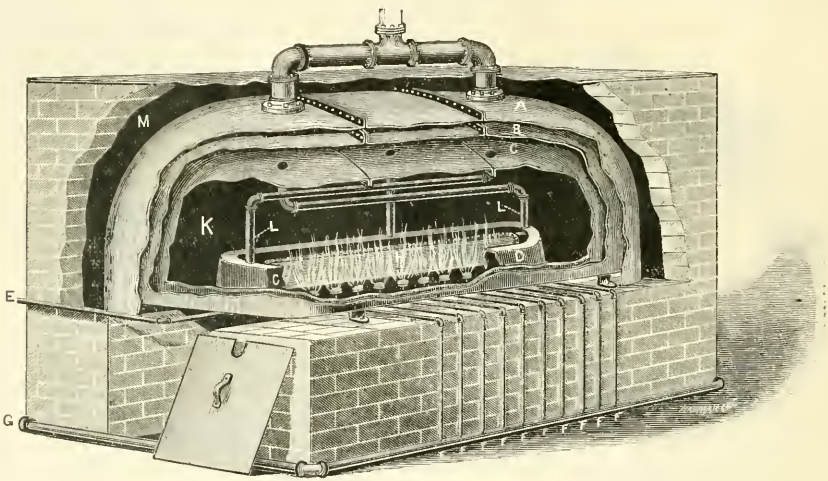
From G. W. B., *Baltimore.*—I would ask for information, through the columns of *The Metal Worker*, regarding the process to be used in brazing steel.

Answer.—In the brazing of steel greater care is required than with iron, as the former is more liable to injury by overheating. The parts to be joined are filed or scraped so as to be bright and clean, then secured together by wire, riveting or other means. Granulated spelter and borax are to be mixed with a little water and placed over the joint, and the article held over a clean charcoal fire until the moisture is evaporated, so as not to displace the spelter. The article is then to be brought to a cherry-red heat, so that the borax will fuse, also the spelter. After the spelter has run through the joint the article is taken from the fire and allowed to cool; or, if the steel is required to be soft, so that the article can be bent slightly without breaking, it should be left in hot ashes over night, so as to cool slowly. If the article is of small size, the joining can be done by means of silver solder and the blowpipe. It may be found convenient to secure the article in the desired position by placing it on a piece of charcoal and fastening it by means of small wire staples, which can be run into the charcoal. The joint can then be moistened with borax and water and the silver solder placed on in small pieces. The blowpipe flame is then brought against the joint, causing the silver and borax to fuse. If difficulty should be experienced in obtaining the proper degree of heat by the above method, small pieces of charcoal can be piled about the joint and the blowpipe flame applied as above described.

STEAM AND HOT WATER.

The Ware Hot-Water Heater.

The Ware Automatic Heat Generating and Regulating Company, 403 Market street, Philadelphia, are offering to the trade a new form of hot-water heater, using gas for fuel, a broken view of which is shown in the accompanying illustration. In construction it consists of an outer water chamber of the shape of an elongated beehive, and two inner chambers of a hight about one-fourth of their length, a cross section of which would show a sharp-pointed oval. The outer chamber receives the return pipe at the bottom and supplies the flow pipe at the top. The inner chamber at the bottom connects with the outer chamber by a pipe, and another pipe leads from the top of one end of the inner chamber clear back to the other end, where it enters the outer chamber: These chambers are made of sheet metal, and are incased in a brick wall, with an arching galvanized sheet-iron roof. They are set over a space that would ordinarily be an ash pit, at the back of which is a collar, to which the pipe that runs to the chimney is connected. In this space a series of independent specially constructed atmospheric burners for gas are so located that the tops of their flames are divided by the sharp edge of the inner water chamber. The heated products of combustion, instead of passing direct to the chimney, rise and impart their heat to the inner walls of the outer water chamber, when they drop below the line of the burners into the space from which the chimney connection runs. The result is that the heat generated is utilized very completely. The burners are independent, so that one, or as many as are desirable, may be shut off as required. A pilot light is so arranged that it burns continually, and, by a specially devised and sensitive thermostat, the gas to the other burners is automatically turned on or off as the temperature of the apartment in which it is located varies from 70° to 72°.



The Ware Hot-Water Heater.

Erecting a Heating Apparatus.

BY HELIOS.

After securing an order to erect a steam heating apparatus, look over the building carefully, and if the owner has floor plans of the building take them and make a copy, then lay out all your radiation and run all the steam and return mains. Make them as short and direct as possible, yet keeping them out of the way, so as not to interfere with the comfort of the occupants. Lay out all the work on the plan, for it will save time in placing the work, and what will not work out on the plan all right will not in the building. Look at the chimney that is to be used and see that the flue is of the right size, that it is straight and the same size its entire length, that there are no openings into it for fire places or stoves, and see that the top is above the highest point of the roof and that there are no buildings near that will interfere with the draft. Be sure that the flue is all right, as the entire success or failure of the apparatus depends upon the boiler having a perfect draft. Set the boiler on a good solid foundation. Be sure that it is level and secure. If you use a portable sectional boiler be careful and follow the directions that come with the boiler for its erection. Be sure that all joints are tight. If the boiler is brick set, use good mortar and first quality brick, and if any part of the brick setting is used as a flue have all joints well filled up and the flue plastered smooth and kept full size, and be sure that everything is in perfect order. After the boiler is all set up, remove the earth, rubbish and dirt of every kind; clean everything up. There is nothing that is so annoying to the owner of a building as to have workmen come into a building, fill the cellar full of dirt and rubbish and leave it, so clean everytning up and you will make a good impression at the atart.

Connect the smoke pipe from the boiler to the smoke flue, and do not have over one elbow in it if possible. If without any, so much the better. Next place the radiation in the rooms they are to warm. Screw on the valves and mark on the floor the place for the pipe to come through; then take a feeling gimlet and bore through, and see where the pipe is coming through, that it is out of the way of all timbers and that there is nothing in the way of making the connection. Use a plumb bob for laying out the holes for all risers, and be sure that they are plumb and straight. If the floor has to be taken up cut the hole for the pipe before taking it up. Use great care in taking the floor up, and cut it off close to a joist, so that a strip can be nailed on to hold the flooring in place. After the connections are made replace the floor in good order and secure with screws. Never use nails. If the building is occupied try and keep everything as clean as possible. Clean up the room you are working in before going into another. Keep your hands off the walls, doors or wood work, and when you leave the room leave it in as good order as it was when you entered. When all openings have been cut to run the steam pipe through, commence at the boiler to run

the main steam pipe. Take a ball of twine and run it through the cellar for a line for the main steam pipe; bore the holes over this line for the pipe hangers, screw them up and regulate to grade the pipe. Never connect the steam or return pipes to a boiler without placing flange unions in them at the boiler, so if at any time it is necessary to make repairs to the boiler it can be done without cutting the pipe. This may save hours of time and a large expense in making new connections. Run the main steam pipe, having the highest point at the boiler, and let it drip away from the boiler in the direction that the steam flows. The main steam pipe should have a fall of not less than ½ inch in 10 feet. Leave all necessary openings for drip pipes in the main, so that no water can collect in them, for if there is any place where the water cannot drip out it will cause that awful hammering noise so often heard in an imperfectly erected apparatus.

After the main steam pipe is in place run all riser and radiator connections. Be sure and allow for expansion and contraction of the piping. Place tin pipes around all steam pipes where they pass through floors or partitions, and place ceiling and floor plates around all pipes. One of the most important parts of a one-pipe steam warming apparatus is to have tight radiator valves. A valve that will not shut tight and keep all steam out of the radiator will cause no end of trouble. If the valve leaks the steam will pass into the radiator and fill it with water. When a valve is opened and the steam strikes the cold water it will cause a hammering noise, and if the air valve is opened it will force the water out. If you have automatic air valves on the radiators without drip pipes from them and the radiator valve does not close tight, the radiator will fill with water and run out the air valve and all over the floor. The best plan is to always use automatic air valves on the radiation and run drip pipes from the air valves. But in running the drip pipes never use black iron pipe, as it will soon fill up with rust and be of no use. Use only the best valves, for they are the cheapest in the end. After you have run all the piping to the radiation screw on the valves and connect to the radiator with the union on the radiator valve. Never connect up a radiator without using a union radiator valve, as the carpets have to be taken up, and with a union valve it is only a very little work to unscrew the union on the valve, and the radiator can be removed. After all the radiation is connected to the steam pipe, run the return pipe in the cellar; also connect all necessary drip pipes from the steam to the return pipe.

On a one-pipe steam apparatus keep the return pipe above the water line in the boiler, if it is possible to do so. If not, keep all you can above. All returns must have a pitch to the boiler of ½ inch in 10 feet. Hang the return pipe under the steam pipe and keep it as near the steam pipe as possible at the far end. Place automatic air valves on the end of each branch main steam pipe and on the return pipes above the water line at the boiler. After all the connections have been made, start the fire and see if there are leaks in any of the joints. If there are, stop them; do not leave the job with a leak of any kind. If everything about the apparatus is all right, while the piping is hot paint all steam and return pipes and all iron work on the boiler one coat of black asphaltum varnish. This will keep the iron work from rusting. When the radiation is hot, clean it off, and if the radiators are to be bronzed, mix your bronze powder and bronze liquid in a clean dish. Do not have it too thin, but just right so that one coat will cover all in good shape. Be very careful in applying the bronze not to cover all the wall and floor around the radiator. Place old papers between the radiator and wall and on the floor. Be sure that the radiators are covered all over; leave no places on them where the iron work will show through.

No steam apparatus is complete without having the steam and return pipes in the cellar covered to prevent the radiation of heat in the cellar. Any of the sectional pipe coverings on the market will make a good job; or they can be covered with asbestos paper and hair felt. If hair felt is to be used, first cover all the pipe and fittings with asbestos paper. Cut this in strips to go around the pipe, thoroughly wet it and cement to the piping when it is hot. Be sure and cover all the pipe and fittings. Now take two boards about 6 inches wide and 8 feet long and nail a strip across the ends, leaving a space about ½ inch between the two boards. Take the measurement around the pipe and lay the hair felt on top of the two boards. Measure from the end of the felt to the space between the two boards, take a knife and cut down between the two boards, cutting off the felt. Place the felt on the pipe and secure with heavy twine. Wind the twine around the hair felt about ½ inch apart. Next cover the hair felt with heavy cotton cloth or canvas sewed on. In placing the cloth over the hair felt have it put on smooth and leave it all in good order. Before leaving the job clean up everything, leave nothing in the building, and be sure that everything is finished up in full accordance with your contract, for if you have to come again to do any work it will cost double what it would to have finished all before leaving. If you want to make a success of the heating business be very particular in doing your work. Use only the best materials, have the heater and radiation of ample capacity, do everything in a workmanlike manner and every apparatus placed will bring you orders for many more.

HEATING NOTES.

The New Jersey Heating & Mfg. Company, at 36 Mechanic street, Newark, N. J., in addition to installing steam heating plants, have a power plant and pipe cutting and threading machines, and make a specialty of cutting pipe to sketch.

A German paper reports that in Aix-la Chapelle a whole street block of houses is being built so as to be entirely warmed by steam from a single boiler, which also supplies the engine to work the electric light, while all the cooking is to be done by gas.

Early in the fall of 1892 Curtis & Curtis of Bridgeport, Conn., manufacturers of pipe cutting and threading machinery, applied for space at the Columbian Exposition in which they hoped to make even a better showing than they did at the Paris Exposition, where they were awarded the medal for pipe cutting and threading machinery, but they were informed that there was no room, and that they could not obtain so much as 6 feet square, and with much regret they were obliged to give up the idea. On April 15 they received a telegram from Superintendent Robertson, asking if they could occupy a space by April 28. They answered "Yes," and by great efforts they shipped their entire exhibit on the third day thereafter. They say that, while their display is not as elaborate as it would have been had they had more time, they still feel that they are well represented. Their position is one of the best in Machinery Hall, being 15 x 17 feet on the corner of two of the chief aisles, and officially known as Annex Section 13, Column J 38. Walter Wright is in charge, and Messrs. Curtis & Curtis hope that all their friends, customers, and in fact, all who are interested in their class of machinery, will make their space headquarters while at the exposition.

Sealed proposals will be received at the office of the Supervising Architect, Washington, D. C., until May 31, for all the labor and materials required for the alterations in the heating apparatus of the U. S. Court House and Post Office Building, Philadelphia, in accordance with drawings and specifications, copies of which may be had at the office of the Supervising Architect, at Washington, or at the office of the custodian, at Philadelphia.

John Davis whose foundry is at Second avenue and Eleventh street, Brooklyn, takes pride in the fact that a leak was found in but one out of 130 hot-water boilers made for John A. Scollay.

The demands for steam and hot-water boilers for heating purposes made upon the Gorton & Lidgerwood Company, 96 Liberty street, New York, are greater than in the same month of preceding years. The service rendered by their goods during the past winter has been the cause of their receiving many pleasant letters from customers.

John A. Scollay, at 71 and 74 Myrtle avenue, Brooklyn, reports an increasing business in hot-water heaters. Another store next door has been secured to give him the necessary accommodations to meet his demands.

The American Radiator Company, 92 Centre street, New York, have secured a well qualified representative in J. D. Murphy, who will travel from this office. He spent several years with the large steam fitters' supply house of John Maneely & Co. of Philadelphia, and afterward assisted the management of the Steam Engineering Company of the same city in installing heating and ventilating plants. With a fund of information and a lively interest in his business, pleasure as well as profit to the trade should result from his visits.

It being necessary to have sufficient space to display samples of the Capitol, Bolton and Hecla heaters, John W. Mills, representing the United States Heater Company of Detroit, has removed from the Ogden Building to more commodious quarters at 100 Lake street, Chicago.

The office and salesroom of the Wilcox Water Heater Company have been removed from 238 Lake street to 297 Wabash avenue, Chicago.

A telegram from Cape Town announces that the mining engineers of the Southwest Africa Company have reported the discovery in the company's territory of extensive deposits of copper ore a few miles north of the Otavi mines in Damaraland.

TIN PLATES.

The New Castle Steel & Tin Plate Company.

Contracts were made for iron buildings and machinery of the New Castle Steel & Tin Plate Company, at New Castle, Pa., during the latter part of April, 1892, and the excavations for foundations were begun May 18. When almost finished the large iron building was blown down by a severe storm on the night of November 17. This was at the expense of the contractors, but it caused a delay of about three months in that building. The extreme cold weather, the mercury having been down to zero for weeks at a time, caused further delay in outside work. Their year is not yet up, however, and they expect to get the plant ready for operation by the second week of July.

The main building is 250 x 110 feet, built by the Youngstown Bridge Company, with columns of the unusual hight of 24 feet. In this building will be four mills and four sets of cold rolls, with room for two additional mills. These are arranged in a continuous line lengthwise of the building, as follows: Two hot mills, Corliss 30 x 60 inch engine, hot mill, two sets cold rolls, space of 10 or 12, two sets cold rolls, hot mill, Corliss 30 x 60 inch engine, and connected direct with the crank of this engine a three-high bar mill to roll the largest-sized billet that is used in tin-bar practice The first two mills mentioned are arranged "old country style"—*i. e.*, one is used for roughing and the other for finishing, each of the remaining ones being used for both roughing and finishing. The engines have unusually heavy fly wheels, weighing from 40 to 45 tons. On one side of this line of rolls are four double heating furnaces, while on the other side are located three sets of shears connected to a single shaft, which is driven by a small engine. Four excellent cranes are placed almost in line with the rolls. The four boilers, 84 x 18, 108 flues each, will be placed just outside the building. The boilers and engines are furnished by the Bass Foundry & Machine Works, Fort Wayne, Ind.; the mills by the A. Garrison Foundry Company of Pittsburgh; the cranes by the Phœnix Hand & Power Crane Company of Cleveland and the castings for the furnaces by the Lloyd Booth Company of Youngstown.

Alongside the rolling mill is the washhouse, 362 x 60 feet and 24 feet high, which will contain 12 tinning stacks, with Morewood five-roll tinning machines and three annealing furnaces of the "St. Louis" plan.

A separate building, 40 x 70 feet, is provided for the machine shop, in which the rolls will be turned and general repairing, &c., done. Power for the machine shop comes from the same shaft which drives the shears in the mill.

A gas furnace for heating billets is located just outside the mill, which will be run by producer gas, and is the design of John Stevenson, superintendent of the wire nail, rod mill, and the Shenango Valley Bessemer steel plant of New Castle, and Robt. Gray, superintendent of the J. P. Witherow Works of New Castle.

A railroad will be built through the plant. The plant was built under the general direction of George Greer, the president. The remaining officers are: Charles Greer, secretary; Wm. S Foltz, treasurer, and Harry Herbert, superintendent. The foundations and brick work, including furnaces, were built under the direction of George Hartland & Sons. The machinery, pipes, &c., were set by George W. Gageby, formerly of Johnstown, Pa. The engines and boilers were designed by Mr. Stevenson. The plans for steam and water piping were gotten up by Mr Gray, and the fittings were supplied by Atwood & McCaffrey and Wilson & Snyder Mfg. Company of Pittsburgh. The design and plans of the rolling mill and tinning department were made by George Greer after visiting all the leading plants in the country The works will employ from 200 to 300 men, besides boys.

The railroad facilities are excellent, four different lines having access to the plant.

The P. & L. E. (Vanderbilt system) and P. & W. (B. & O. system) enter by means of a large trestle, while the Pennsylvania lines and the W. N. Y. & P. come in from the northeast.

Pure clear water is supplied from the company's own dam on Big Run, a considerable stream that comes from the east and runs near the works.

A large brick and cement cistern, an elevated railroad water tank and three large Worthington steam pumps distribute an abundant supply of water throughout the entire plant. Within 1500 feet of the works the fine ores of the Lake Superior region are smelted into pig metal at one of the most modern and complete blast furnaces in this country and taken direct to the Shenango Valley Steel Company's plant and converted into the soft Bessemer steel suitable for all the requirements of the very finest sheets for tinning and for deep stamping. It is probable that before the mill is started the direct process of converting the pig will be in operation at the Shenango Valley plant.

SCRAP.

JOHN HAMILTON, Pittsburgh, Pa., manufacturer of Hamilton's Best Re dipped American Roofing Tin, is meeting with an excellent demand for this brand of plates, and is shipping the product about as fast as made. Mr. Hamilton has recently furnished a number of boxes of this brand of roofing plate to George W. Johnson & Son, Wheeling, W. Va., for roofing a new building now being erected there by that firm This order, we understand, was secured in the face of very strong competition, foreign plates being offered at extremely low prices. Mr. Hamilton is also meeting with a good demand for his roofing plates from railroad companies, and has already furnished several large lots to be used in roofing car sheds and other railroad buildings.

THE GLENDALE TIN PLATE COMPANY are reported to be turning out 500 boxes of roofing plates weekly from their Pittsburgh works. Three brands of terne are made, namely, Optimus, a guaranteed redipped plate of high grade; N F., a first quality, heavily coated plate, claimed equal to M. F., and Bonus, a fine charcoal roofing plate, all coated by the palm oil process, hand dipped. They are made from black sheets of American rolling, and are said to be meeting with great success. An extension of the works is in contemplation. The company's selling agent is W. P. Loughry, 81 John street, New York City.

EASTERN TIN-PLATE MERCHANTS report trade as extremely dull. This is attributed in part to the present unsatisfactory condition of general business, but largely to the extraordinarily backward season, which has retarded building operations some six weeks beyond the normal period. This condition is expected to right itself, however, as a good deal of building is in prospect, and a considerable demand for roofing plates should develop in the course of a month or six weeks.

IT IS REPORTED that the Youngstown Tin Plate Company recently organized at Youngstown, Ohio, for the manufacture of Tin and Terne Plate, are considering the advisability of removing their plant to Girard, Ohio. Citizens of the latter-named place have offered the concern 2 acres of ground and a suitable bonus in order to secure the industry, and it is understood that this offer is now under consideration.

ANOTHER DEPARTMENT in the Falcon Tin Plate Mill of Niles, Ohio, will be put in operation this week One set of rolls will be started turning out the black plates, which will be afterward coated. This will give a number of men employment. The balance of the mill will be started as soon as the different departments are in readiness. Arrangements are being made to inclose this plant by a high fence.

CANNERS' REQUIREMENTS in British Columbia will probably be considerably above the average this year. Preparations are being made for an exceptionally busy season, expectations pointing to a larger catch of salmon in the Fraser River and other points than in any year since 1889. The probable output is put down at 600,000 cases of cans. The demand for coke tin for canning purposes, in all parts of the country, is reported to be active and growing; and should the Southern fruit crop come up to expectations, that branch of trade should receive a decided impetus this year.

THE NEW TINNING PLANT of the Morewood Tin Plate Mfg. Company at Elizabethport, N. J , is now complete, and the works are in full operation. Six bright tin stacks and two pots for coating terne plates are running night and day to keep pace with orders. The company are in possession of one of the most complete tinning establishments for its size in the country. The bright and roofing plates turned out are generally indentical with the brands manufactured at the same firm's works at Swansea and Llanelly, Wales.

THE NEW TIN-PLATE MILL of the Falcon Tin Plate & Sheet Iron Company went into operation on May 9, starting with 30 hands. It is stated that this number is to be increased to 75 workmen.

THE TINNING PLANT of the Laufman Tin Plate Company, at Butler Junction, West Penn Railroad, Pa., is reported to be fully active. The daily output of the works is now 100 boxes of roofing plates. Under their former name of Pittsburgh Electroplating Company, the Laufman Tin Plate Company were among the pioneer tin-plate manufacturing concerns of the United States. Their terne plates are all produced by a process of their own, and are double-dipped, pure palm-oil process plates. The office of the company is in Pittsburgh, Germania Bank Building.

THE ADDITIONS to the rolling mill and tinning plant of the American Tin-Plate Company, Elwood, Ind., are progressing rapidly, and will, it is said, be available by July 1 or shortly after that date. These additional facilities will bring the capacity of the works up to 4000 boxes of tin and terne plates weekly, doubling the present output.

THE INDIANA Tin Plate Company, Atlanta, Ind., have eight tinning stacks in operation. The plant is said, by one who has recently visited it, to be one of the best of its size thus far built in the United States.

A CARLOAD OF TIN ORE from the Harney Peak tin mines has been received in New York this week by the Crooke Smelting and Refining Company, Burling Slip. A portion of the metal, when smelted, is to be sent to the World's Fair for exhibition.

THE AMERICAN TIN PLATE COMPANY, Elwood, Ind., report quite a pressure of orders for their plates, of which they are now turning out three grades under the brand of "Elwood," namely, "Elwood Coke," which are guaranteed equal to "J. B." imported plates; "Elwood Charcoals," equal to "Allaway"; and "Elwood Ternes," equal to "Worcester" grade. These are all claimed to be of even better quality than the corresponding grades of imported plates, and are of full weight. They are now made of standard sizes, but with the company's recently installed bar mill, which is about to be started up, they will be ready to furnish them in any sizes required. The American Tin Plate Company say that quite a pressure has been brought to bear on them to stamp their terne plates, but that so far they have declined to do so, holding that stamping a plate impairs its quality, as the stamping with small letters fractures the fiber of the metal, so that when placed upon a roof it will not stand as well as one that is not stamped. They feel a pride in their plate, and wish to give the purchaser an article which will be lasting. The company state that they have had considerable argument on this head with large dealers in the West, but they have all accepted the views of the firm, and take their plates unstamped. About 2500 boxes a week are now being turned out from the Elwood works.

THE LEECHBURG FOUNDRY & MACHINE COMPANY, Pittsburgh, have recently commenced the manufacture of chilled and sand rolls and have received orders for this class of product from Wallace, Banfield & Co., Limited, Irondale, Ohio, and the United States Iron & Tin Plate Mfg. Company, Demmler, Pa., and others.

The startling novelty of a surplus in the Spanish national budget, if followed by an improvement of roads in the interior, might signalize the beginning of national rejuvenation and development.

Prize Competitions.

$25.00.

Prize Competition No. 20.
(Reopened.)

SUBJECT:

A Reliable System for Securing the Correct Charging of All Goods Sold on Credit.

This competition closed May 6, but in view of the importance and practical nature of the subject and the exceptionally few replies which have been received from the trade we re-announce it as above and extend the time up to which responses will be accepted to June 10. The interest of this competition and the importance of having some satisfactory method of accomplishing the desired result is referred to in the following letter from a correspondent who, it will be observed, calls attention to the carelessness in this regard which is characteristic of some merchants, and expresses the hope that among the contributions received will be many of practical value:

The answers to the competitions which have been recently published in *The Metal Worker* have been read by me with more than usual care. Competition No. 20, "A reliable system for securing the correct charging of all goods sold on credit," to me, is one of much interest, and I trust you may soon find a place for the answers to it in your paper. There is no other leak about a store, in my opinion, that requires more thorough calking than that occasioned by allowing goods to go uncharged. It is not unusual to hear a proprietor, when looking over the day's business, inquire, "Has this been charged?" It is the proprietor's place to have the business so systematized that errors of this or of any other kind should be of rare occurrence; and when an error is made, under some unusal circumstances, a remedy should at once be provided to prevent its happening again. The proprietor should hold himself personally responsible for such mistakes, because he has failed to provide against it. From the large amount of credit business done, and done by many firms whose system in other things could not well be improved upon, I look for very satisfactory solutions of this question in the replies which you will publish.

We hope, therefore, to hear from many in the trade with practical suggestions or descriptions of systems in use whereby the charging of all goods is assured. How to avoid charging undesirable parties without giving offense, and how to avoid charging small amounts are also points which should naturally be considered in replies.

Those intending to compete are reminded that it will not be necessary to write long essays, but that comparatively brief and business-like answers will be favorably regarded as meeting the purpose for which these competitions are announced.

This competition will remain open until June 10, 1893.

The following prizes will be awarded:

First prize.....	$12.50
Second prize....	7.50
Third prize.....	5.00

The prizes will be awarded for answers which, in the judgment of the committee of award, are most suitable for publication and of the most general interest. We shall have the privilege of publishing any or all of the contributions received.

Replies are to be received not later than June 10, 1893. They should be addressed as follows:

DAVID WILLIAMS,
96-102 Reade street,
New York.
Prize Competition No. 20.

The committee to whom the contributions in Prize Competition No. 10 were referred have awarded the prizes as follows:

First Prize of $50 to FRED. MACEY, Grand Rapids, Mich.

Second Prize of $25 to H. P. KING, Portland, Ore.

Third Prize of $15 to G. T. EVANS, Pittsburgh, Pa.

Fourth Prize of $10 to FERDINAND TUSCH, Brooklyn, N. Y.

Other Competitions which have closed are now in the hands of the Committee of Award, who are giving careful attention to the claims of the different contributions. From the number of these and the evident merit of not a few of them, we are assured that a great deal of valuable information and suggestion will be put at the disposal of the trade.

The Weekly Prize Competitions noted below are now before our readers and remain open until the dates named:

No. 22. Closing May 20.
The Best Manner of Presenting and Collecting Book Accounts.

No. 23. Closing May 27.
Three or more Subjects for Prize Competition.

No. 24. Closing June 3.
Short Methods of Figuring Discounts.

No. 20. (Reopened.) Closing June 10.
A Reliable System for Securing the Correct Charging of All Goods Sold on Credit.

Another subject will be announced in our next issue.

The Philadelphia Board of Health has issued a bulletin reminding citizens of the necessity for cleanliness in every respect, that garbage collections be avoided; also filth of every description; that drainage be kept free from obstruction and whitewash freely used. Offenses against the law governing these matters will be promptly punished. Pestilence comes only by invitation.

PLUMBING and GAS FITTING.

To Local Associations of Master Plumbers.

We take pleasure in printing the following item at the request of the Milwaukee Master Plumbers' Association:

In order that the Master Plumbers Association of Milwaukee may be prepared to receive all delegates, it is requested, and is very important, that each local association send to A. R. Schwind, Recording Secretary, 123 Sycamore street, Milwaukee, the number of delegates and accompanying ladies, so that the association may better prepare for their reception. It is the intention of the association to meet the delegates at the depot, and it is requested that delegations inform the secretary as soon as possible of the name of the road over which delegates will arrive, and the time of arrival. Delegates will, by giving this their immediate attention, greatly facilitate the work of the local committee.

Aerating Pump.

The aërating pump illustrated in Figs. 1 and 2 is being offered by the Sandwich Enterprise Company, Sandwich, Ill. The

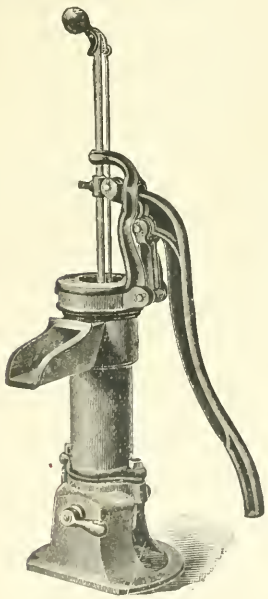


Fig. 1.—Aerating Pump.

pump, as shown in Fig. 1, has a brass cylinder; steel piston rod, guided; brass valve plunger; compressed steel handle pins; is painted and striped with gold bronze. As illustrated in Fig. 2, a stream of air is forced down to the bottom of the cistern, agitating the water and mixing the air with it, to take out odors, and to purify the water. In operation the ball at the top of the rod is tipped so that the letter A is uppermost, and the lever at the base is turned the same way. Then by working the pump handle the air is forced to the bottom of the water. After the ball and lever are turned to their original positions and the pumping continued, water is drawn from the cistern as with an ordinary pump. The manufacturers

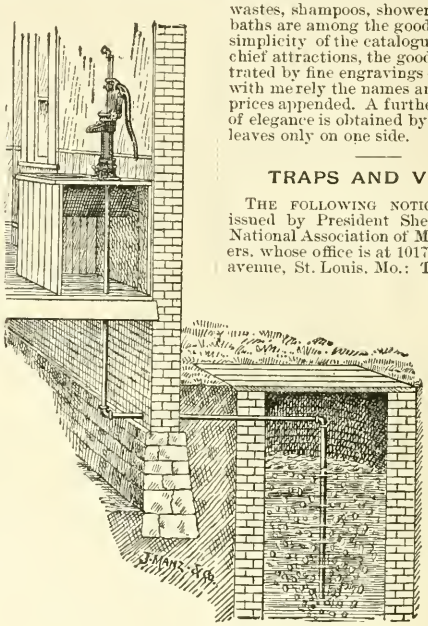

Fig. 2.—Operation of Aerating Pump.

state that a few minutes' pumping air each day will sweeten the foulest cistern, and that when once sweet a few strokes of air after pumping water will keep it pure.

The Henry McShane Mfg. Company,

Baltimore, Md., publish fine catalogues of some of their specialties. One of them relates to galvanized iron and copper range boilers, expansion tanks, air receivers, &c. In mailing this catalogue to the trade they call attention to the superior grade of this class of work, which they are now manufacturing. They add that they have spared neither pains nor expense in equipping their plant with the latest improvements in machinery for this work. Their galvanizing works are provided with testing apparatus and the boilers are carefully tested after galvanizing, to make sure that the seams have not been affected by heat during the process. The catalogue, printed on a fine grade of paper, shows general and broken views of the goods noted, besides giving tables of capacities, sizes and prices. The binding is in rough white paper, with printing in red ink. A larger catalogue issued by the same firm is of oblong shape, built up of separate sheets, like a pad, and bound at the top by a cord. The goods noted are included under fine sanitary specialties. Lavatory legs, towel racks, brass sponge holders and soap cups, brackets, brass traps of many kinds, basin wastes in various designs, bath wastes, shampoos, showers and needle baths are among the goods noted. The simplicity of the catalogue is one of its chief attractions, the goods being illustrated by fine engravings on fine paper, with merely the names and the lists of prices appended. A further impression of elegance is obtained by printing the leaves only on one side.

TRAPS AND VENTS.

THE FOLLOWING NOTICE has been issued by President Sheehan of the National Association of Master Plumbers, whose office is at 1017 Washington avenue, St. Louis, Mo.: The Executive Committee of the National Association of Master Plumbers will meet at the Hotel Pfister, Milwaukee, at 10 o'clock a. m., Monday, June 12, to transact such business as may come before it. Any one having any business to present to the committee will please forward the same to this office immediately.

JAMES ARMSTRONG of New York and Brooklyn finds with the growing popularity of wrought-iron pipe for drainage an increased demand for his special recessed pipe fittings, which are made for pipe from $1\frac{1}{2}$ to 10 inches diameter and of variety to meet all requirements.

THE ISOTHERMAL & PLUMBING COMPANY of 1721 Chestnut street, Philadelphia, are introducing a new feature in regard to heating and plumbing. They offer to heat any house, supplying fuel and all services, examine, repair and clean heaters, inspect private or public plumbing, drainage and lighting arrangements, weekly, monthly, or otherwise, and make necessary repairs, prepare plans and specifications for plumbers and undertake general plumbing work, undertake disinfection of buildings and perform any and all duties pertaining to heating or plumbing. They have competent workmen on hand day and night for emergency

service at any hour, and they state that their facilities in this direction have been much appreciated. They also deal in heating and plumbing supplies and carry a line of heaters, baths, closets and other goods in stock. They are putting upon the market Billings' thermostatic regulator for hot-air furnaces, and Billings' rheostatic governor for stoves and ranges, and are issuing circulars descriptive of these devices.

THE ESSEX LEAD WORKS, started by Frank Kellogg at Newark, N. J., a few years ago, has grown into a plumbers' supply house capable of furnishing all that the modern plumber needs. A boiler and engine of 100 horse-power drive the machinery, and are located in a basement. Another portion of the basement contains the lead-pipe making plant. From the melting furnace the lead runs directly into the pipe press, which is supplied with a steady hydraulic pressure by three pumps, and lead pipe is turned out and coiled ready for shipping in a few minutes. A variety of dies enable the making of different thicknesses of pipe, as well as all the standard sizes. The balance of the basement is used for carrying a stock of cast-iron pipe both of standard weight and extra heavy. On the first floor is the office and a display of sanitary specialties and modern porcelain plumbing goods. The rest of this floor is arranged to utilize space and for the convenient handling of a line of supplies for plumbers, gas fitters, machinists, factories and mills. The line comprises everything from the rough fitting to the handsomest nickle-plated fixture. Another special line is the Tanite emery wheels and grinding machinery, which find a ready market in so great a manufacturing center as Newark. Meeting the demands made upon them as they grew, the Essex Lead Works have found it necessary to secure another building at 57 Mechanic street, a few doors away, where they carry wrought-iron pipe and other bulky goods and have stabling for their teams.

IN 1826 the house of C. S. Osborne & Co., now at the corner of Lawrence and Mechanic streets, were established at Newark, N. J. The house have devoted their energies to tool making in two different lines—plumbers' tools and tools and machinery for working leather. The plumbers' tools begin with gas pliers and pipe tools, taking in calking tools, chisels, wooden tools, ladles and solder pots, all of which are high grade, excellent quality being a characteristic of their goods. Washer cutters are to the plumber the most interesting of the leather-working tools, but they attract a wider interest in other sources. A shipment is now being prepared to go to Hindostan, while to Europe, Australia and South America frequent shipments are made. The growth of the business with years finds the basement of their works full of forges, steam hammers and power presses, and in another building the engine to drive the various machinery is located. A visit to the engine room impresses one that the engine was put in yesterday, and pride is taken in stating that it has been working over 23 years, and though the demands made upon it to-day are great, it runs quiet and true. On the first floor is the office and shipping department at the front, while the wood-turning department lumber-drying and storage rooms occupy the rest. Most of the tool handles are made of rosewood, though turn pins and plumbers' tools are made of something tougher, like hickory and maple. The second and third floors contain the polishing and finishing shops and the general machine shop. Recently a special room has been added, with ample side light and a skylight, which is used for making special tools for manufacturing their own goods.

AN AMENDMENT to the municipal plumbing regulations of Wilmington, Del., has been adopted, which rules that in outdoor water-closets all ventilation pipes shall extend above the roof of the closet to a point to be designated by the plumbing inspector. It also provides that in no case shall such a pipe terminate within 12 feet of any window or other opening of any adjoining building.

THE OLD DOMINION MFG. COMPANY of Shendun, Va., are increasing their plant and facilities for producing goods. They are now building the third dry kiln, and on its completion, they say, the total drying capacity will be equal to about 80,000 feet of lumber. We are advised by those in charge that an average of about 7000 feet of various hard woods used in the manufacture of closet seats, tanks, tank boards, bathtub rims, washtub rims, &c., is being cut up each day. The firm also make their own metal work for water closet tanks, such as valves, ball cocks, levers, &c., having recently sent down 20 additional men for this department. They are now employing 212 men altogether, and C. H. Rose, heretofore looking after the New York end, has found it necessary to assume charge of the works at Shendun, which he has done since April 1. Otto Hahn, who has been connected with the company since their organization, mainly employed selling the goods, is now in charge of the office and warehouse, at 242 Water street, New York, where is carried a stock to fill requisitions for near-by delivery. An average of a carload of finished work is being forwarded from Shendun every working day. They have their own tinning plant for tinning copper, and also machinery for hard rolling or planishing the copper sheets after being tinned.

THE WATER OVERFLOW PREVENTIVE COMPANY, 93 Grand street, New York, effect a novel insurance against damage by water overflow, by preventing the building from being locked until the water supply is shut off. The method consists in attaching to the stop-cock lever a catch which fits in a lock that is so located that the catch is held in it when the water is shut off. The lock is made to fit the main door key, and this key is used to release the catch so that the lever can open the stop cock and let the water on. The key is securely held in the lock and the building cannot be locked until the water is turned off, which releases the key so that the building may be locked. It prevents this duty being forgotten, which has often resulted in a flood that destroyed valuable merchandise.

THE DELAMATER IRON WORKS, 87 South Fifth avenue, New York, find with the increase of flats a steady demand for the improved Ericsson hot air pumping engines. They suggest that the pumping engine is entitled to a share of the credit of causing the increased valuation in New York City property, for without the water conveniences which they make possible no one would as soon occupy the top flat as one lower down.

KILLER & BEEBE of 129 Beekman street, New York, have recently renovated their premises and put them in first-class shape for promptly handling their business. The firm are now in shape, we understand, to accept the largest orders, and as they give employment to mechanics of the best grade, satisfactory work is guaranteed.

THE MASTER PLUMBERS' ASSOCIATION OF WASHINGTON, D. C., have elected the following delegates to attend the national convention held in Milwaukee next month: John Mitchell, president; Edward J. Hannan, James Ragan, James Lockhead and Donald Williamson.

The L. Wolff Mfg. Company

of Chicago have just issued an advance edition of their catalogue B, covering plumbing specialties. This work has been in preparation for a long time, but probably another year will be required to complete it. So determined are the company to secure the best results possible in making preparations for their catalogue, that they have their own photographing facilities and their own engraving department, stopping at no expense to get really artistic work. This edition of the catalogue—called merely an advance edition—would be creditable to any house if nothing further were attempted. It is a most gorgeous work, comprising some 250 pages, each 10 x 14 inches, embellished with the most exquisite engravings, many of them lithographed in colors, as well as unusually fine letterpress, on very heavy paper, bound in a substantial terra-cotta cloth cover, with titles stamped in gilt. The scheme of the catalogue is to cover all lines of the company's specialties, leaving some of their goods in the several lines to be treated in that part of the catalogue which is yet in preparation. On glancing through the advance catalogue it would seem that further additions would be unnecessary. The variety shown here should satisfy the most exacting taste and silence the most captious customer. Bathtubs are first considered, the place of honor being given to enameled iron baths. The L. Wolff Mfg. Company have cut loose from the Standard Mfg. Company, and now make their own goods in this line, having recently provided facilities for doing their own enameling. No less than 26 styles are shown. Next follow three styles of porcelain baths, then five kinds of copper baths, with seat and foot baths appropriately bringing up the rear. Needle and shower baths consume no less than 20 pages. The water-closet line, however, is immense, 76 pages being required to do the subject adequate justice. Lavatories and lavatory fittings take 40 pages. Among the designs for lavatories are a number of the most ornate character, the variety ranging from the most palatial article demanded by a fastidious sybarite to the plain every-day piece of furniture within the means of the most humble. Lithographic representations duplicate the exact patterns and colorings of decorated wash basins. Pantry and kitchen sinks and fittings absorb 26 pages of the book. Slop sinks and washtubs take 24 pages. Range boilers are supplied for vertical and horizontal use, either galvanized or of copper, or with copper coils inside for heating water with steam. Galvanized range boilers are made from 18 to 192 gallons capacity. Although but four pages are devoted to this subject, a great deal of interesting information is given. Urinals cover 16 pages, cuts being given of urinal stalls and all kinds of fittings. Limited time has prevented the company from showing all they desire to present with regard to urinal stalls, earthenware urinals, brass inlet connections, traps and automatic tanks, &c., but an illustrated supplement will soon be ready for distribution, dealing with this special subject. The advance catalogue is not for general distribution, but is only intended for plumbers of good standing in the trade and for jobbing houses whose location requires them to maintain a department of plumbing supplies and specialties.

House Warming.—IX.

From the foregoing it is obvious that in order to obtain the most economical character of combustion (irrespective of the manner of utilizing the resultant heat) it is important to supply exactly the proper quantity of oxygen. Any amount less than we find necessary as indicated by the formulæ will result in imperfect combustion; while an excess—though it does not act as against the complete chemical combination—will abstract from the fire and carry to the chimney a corresponding quantity of the heat generated and therefore become a source of wasteful loss.

And as we have seen that atmospheric oxygen—our only natural source of supply—is moved with four times its bulk, or three and one-half times it weight, of nitrogen $\left(\frac{14.01 \times 4}{15.96} = 3.51\right)$ the latter also must be heated to the same temperature as the uncombined oxygen, and will therefore carry off a certain additional number of heat units without useful effect. Beyond this fact, and that it is an inevitable diluent of the only available oxygen, nitrogen is perfectly neutral in its effects on the chemical reactions of combustion. The oxygen is, as it were, filtered out in its passage through the fire and the nitrogen is left "free"—chemically considered, although more or less intimately mixed, mechanically, with the other products of combustion. The latter, according to the chemical composition of the fuel and the degree of completeness of combustion, will be: Water, H_2O; carbonic oxide, CO; carbonic acid, CO_2; marsh gas, CH_3; olefiant gas, C_2H_4; sulphurous acid, H_2SO_3, and some other unimportant compounds in small quantities, dependent on the nature of the fuel.

In the destructive distillation of hydrocarbons in the production of illuminating and fuel gas, there occurs a chemical reaction resulting in the combination of certain quantities of nitrogen and hydrogen in the proportions of one equivalent of the former to three of the latter; and this—expressed by the formula NH_3—we see, by Table XXI, to be ammonia. This, however, need not be considered, as it has no important bearing on the subject in hand.

AIR NECESSARY FOR COMBUSTION.

To calculate the quantity of air necessary for perfect combustion of our fuel, we must have the chemical composition of the latter, as obtained by analysis.

Referring to the tables given in the earlier portion of our remarks, we find for bituminous coal (Chapter III, page 47, of February 11, 1893) the average composition of the samples analayzed, while it can only be considered as approximately representing this character of fuel, will serve to illustrate the method of calculation by which the required information may be obtained. We have, then:

Element.	Symbol.	Per cent.
Carbon	C	77.5
Hydrogen	H	5.5
Nitrogen	N	1.5
Oxygen	O	7.0
Sulphur	S	1.7
Ash	..	6.5

In order to facilitate calculations, the atomic weights of the ordinary elements generally used are: Carbon, 12; oxygen, 16; nitrogen, 14; sulphur, 32; water, 18; carbonic oxide, 28; marsh gas, 16; olefiant gas, 28. Of course, for exact results we must use the decimals given in the table.

Considering first the carbon, we have 77.5 per cent., or say 0.775 pound, in 1 pound of coal. The product of the complete combustion of this element is carbonic acid, CO_2, which indicates that our two equivalents of oxygen necessary must weigh, not $16 \times 2 = 32$ pounds, but by the rule of proportion—12, the atomic weight of carbon, is to 0.775, the given weight in pounds, as 16, the atomic weight of oxygen, × 2, is to the required weight in pounds of the latter, or $0.775 \times \frac{16 \times 2}{12} = 2.067$ pounds.

Expressed as a formula, it will read: Weight in pounds of the combustible × [(atomic weight of oxygen × number of equivalents) ÷ (atomic weight of combustible × its number of equivalents)].

With reference to hydrogen, we must remember the presence of free oxygen, which, as stated in Chapter II, February 4, affects the amount of available hydrogen. By the formula, hydrogen $= H - \frac{O}{8}$ we have 0.055 pound, $- \frac{0.07}{8}$ = 0.04625 pound, for which a supply of oxygen is required to burn it to water, H_2O; then $0.04625 \times [(16 \times 1) \div (1 \times 2)] = 0.37$ pound oxygen. For the 1.7 per cent. of sulphur, to burn it to sulphurous acid, H_2SO_3, we find 0.017 pound $\times [(16 \times 3) \div (32 \times 1)] = 0.0255$ pound oxygen required.

As these are the only elements of the analysis with which oxygen combines, the sum of the three quantities found constitutes the theoretical amount required, and this is $2.067 + 0.037 + 0.0255 = 2.1295$ pounds of oxygen. As air, $N_4 + O$, is composed of but one-fifth, by volume, of oxygen, we require to formulate a method by means of which the weight of air necessary to furnish this oxygen may be found.

The formula $N_4 + O = (14 \times 4) + 16 = 72$, atomic weight, which divided into 16—the atomic weight of the oxygen—gives 0.2222, or 22.22 per cent., as the proportionate weight of the oxygen.

Our formula then will read: Weight of air = weight of oxygen in pounds ÷ {atomic weight of oxygen ÷ [atomic weight of oxygen + (atomic weight of nitrogen × number equivalents)]}, and the equation becomes

$$2.1295 \div \frac{16}{16 + (14 \times 4)} = 9.584$$

pounds of air to afford theoretically perfect combustion of 1 pound of coal of above analysis.

To find the volume, in cubic feet, we must guard against the error of considering the air as a chemical combination, instead of a mechanical mixture, as the difference is very great. If the former, the volume would be $\frac{189.7 \times 2}{72} = 5.27$ cubic *feet* per pound, whereas we see by Table XXI it is 13.14. The reason for this need only be suggested to be perfectly plain. As there has been no chemical combination, with the resultant phenomenon of change of volume, we have simply to consider 4 equivalents, by volume, of nitrogen added to 1 of oxygen, which clearly gives 5 volumes.

The equation then will be $\frac{189.7 \times 5}{72} =$ 13.17; and the difference of $\frac{4}{100}$ cubic foot between the result and the volume as per table is due to the fact that the relative proportions of the two elements vary slightly under different conditions or in different localties, and the formula $N_4 + O$ is, therefore, only approximately correct, though very nearly so. The volume in table is derived from experiment, and is therefore to be preferred in exact calculations.

Our weight of air found, then, will be $9.584 \times 12.14 = 125.9$ cubic feet at 62° F. The volume at other temperatures may be found by multiplying by the relative volume (Col. 2 of Table X, February 25) for the desired temperature, and dividing by that of 62°. This is necessary from the fact that the volumes in table are calculated as relative to 32° as unity. If, for instance, the air supply is found by thermometer in room to be 92°, we multiply by 1.122 and divide by 1.061, thus: (125.9 cubic feet × 1.122) ÷ 1.061 = 133.14 cubic feet—an increase, by expansion, of 7.24 cubic feet.

It will be understood, of course, that it is impossible to attain theoretically perfect results in practical application of these laws. There are many causes which operate against the possibility of maintaining the necessary conditions, even though the most elaborate appliances be provided, and the best that can be done is to approximate as nearly as possible to the theoretical requirements. Certainly without some guide the entire subject becomes a matter of guess work, the results of which must be unsatisfactory and very wide of the possibilities as to both efficiency and economy.

In regard to the air supply, it must be remembered that we must consider the manner of its admission as well as the quantity; in other words, it must be so admitted to the fire that it will perform its work of oxidation of the combustible elements of the fuel with as little loss of uncombined oxygen as possible, and also with a view to preventing the valuable products of partial combustion from being carried to the chimney unconsumed, even in the presence of the necessary oxygen.

A Gigantic Ocean Liner.

Ireland, in spite of her "most distressful" condition, is going to be at the top in at least one line. She is building an ocean giant, which is to excel in size and speed even the latest Cunarders, "Campania" and "Lucania." The "Gigantic," now building at Belfast for the White Star Line, is to be 700 feet in length, or 20 feet longer than the "Great Eastern," the biggest vessel ever floated. In breadth, however, she will fall short of that monster by 15 feet; measuring 68 feet, as against the 83 feet of Brunel's failure. Coming to a question of horse-power, the "Gigantic" will be far ahead of anything yet placed on the seas. She is to be fitted with engines exerting a force of 45 000 horse-power, against 7650 of the "Great Eastern," and 15,000 more than that possessed by the "Campania." She is intended to run at the rate of 27 knots, or a little over 31 miles, an hour. The "Gigantic" will well suppprt her name.

Judging from the annual Parlimentary returns just issued relating to the gas undertakings of Greet Britain and Ireland, the companies have not yet been seriously affected by the adoption of the electric light in those countries. The number of gas companies in 1892 was 410 as compared with 405 in the previous year, and the total capital sunk in gas works has risen from $299,390,000 to $318,100,000 in the same period. About two-thirds of this total represents the capital belonging to public companies, and the remainder the value of the plants belonging to local authorities. Both classes exhibit an increase in business during the past year. The gross receipts of the companies increased during that period oy rather more than $5,000,000, and their output of gas by 3,000,000 cubic feet. Owing to increased expenses, however, net profits have fallen about 5 cents per 1000 cubic feet; the average dividend having been consequently reduced from 8.6 per cent. to 8.4 per cent. on capital invested. An addition of 14,700 lamps for the illumination of public roads is noted during the period covered by the report.

The Buffalo Steel Pressure Blower.

The Buffalo Forge Company of Buffalo, N. Y., have placed on the market the steel pressure blower here illustrated, which is designed especially for high-pressure duty, such as supplying air for cupolas, furnaces, forge fires, and for any work requiring the forcing of air for long distances. The main feature of this machine is the solid case, the peripheral portion of the shell being cast in one piece, to which the center plates are accurately fitted. The objectionable "putty" joint is thus dispensed with, and ready access to the interior of the blower without taking it entirely apart is afforded. In Fig. 2 is shown the form of blast wheel which is employed with this blower.

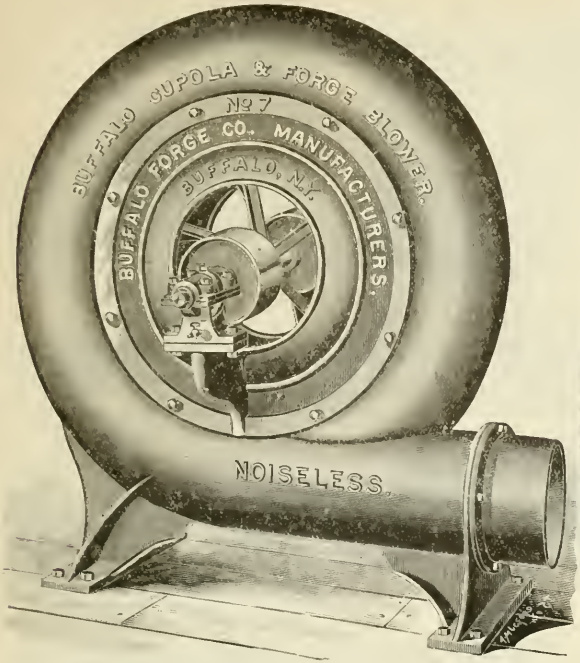

Fig. 1.—BUFFALO STEEL PRESSURE BLOWER.

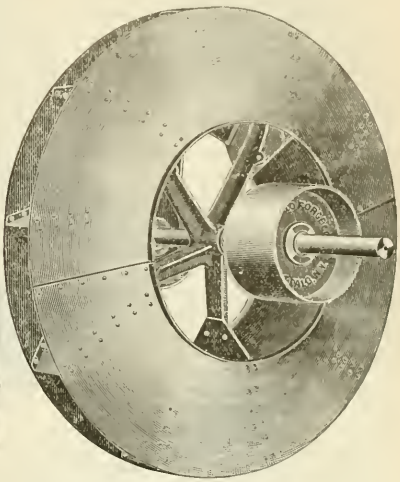

Fig. 2.—Blast Wheel.

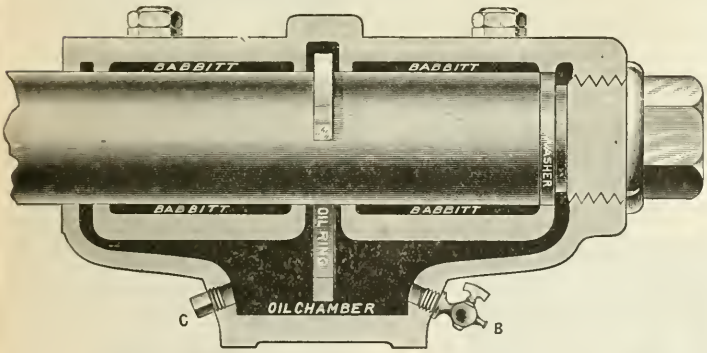

Fig. 3.—Journal Bearing Used on Buffalo Blower.

The journal bearing employed on this machine is illustrated in Figs. 3 and 4. It will be seen that the lower half of the bearing has an oiling chamber, through which the oil ring passes. This oil ring revolves when the shaft is in motion, and conveys the oil from the chamber to the shaft, from which it is distributed by means of chamfered edges the full length of the bearing. The surplus oil then passes to the recesses at the end of the bearing, where it is then returned by means of the channels to the oil chamber. By this method a positive feed is obtained, and the oil supply being regulated by the speed of the shaft, it is impossible for the bearing to heat while there is oil in the chamber. Another feature of this bearing is that a peculiar rattling of the ring occurs when the oil is nearly consumed. This gives warning before the bearing is actually suffering from lack of oil, for it will run for quite a time after this rattling begins without injury. The oil chamber is filled after removing the plug A. By the bib cock B the oil may be readily removed from the chamber, should it become thick by continuous use or dirt.

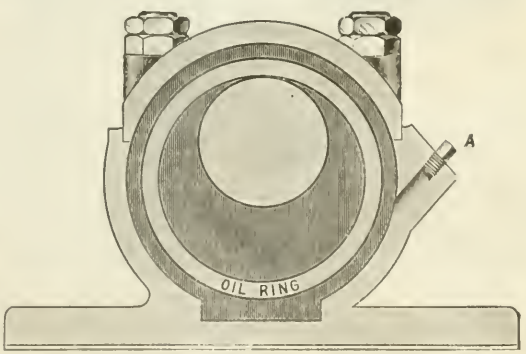

Fig. 4.—Cross Section of Journal Bearing.

Agricultural depression in Great Britain is felt more severely every year, not only among the farming population but among a large class of investors. The latest report of the British Commissioners of Inland Revenue points out that the gross annual revenue of lands assessed under a certain schedule relating almost wholly to the rural districts has suffered a decrease of about $60,000,000 during the ten years ending in 1890–91. Fifteen years ago the landlords' aggregate capital was computed at $10,000,000,000, and that of the tenants at $2,000,000,000. Accepting these calculations as correct, recent investigations show that the landlords' total capital is now a good deal less than $7,000,000,000 and that of the tenants is only $1,350,000,000.

A grand extension of the cable railway system in New York City is proposed by the Third Avenue Railroad Company. The attorney for the company says that the conversion of the horse-power system, together with extensions, will cost $7,000,000.

THE RETAIL STORE.

The National Convention of Retail Hardwaremen.

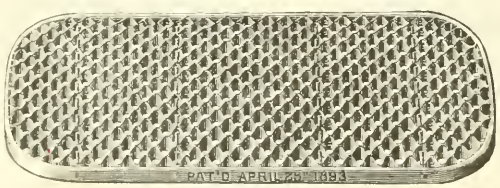
The Retail Hardware Dealers' Association of Pennsylvania, in view of the satisfactory working of their association, and the reasons that exist for similar organizations in other parts of the country, issue the following call to Hardware merchants to attend a national convention in Chicago in September:

The Retail Hardware Dealers' Association of Pennsylvania wishes to call the attention of the retail dealers of the United States to a call for a national convention, to be held in Chicago, Ill., about September 13, 1893. Those who are interested in the formation of a national association are requested to signify their willingness to attend by corresponding with S. S. Bryan, secretary, Titusville, Pa.

As we understand the matter, the principal object is the mutual benefit and protection of retailers against the encroachment of the jobber and manufacturer upon their legitimate trade. It is likely also that other desirable ends would be accomplished, and that an organization of the trade throughout the country might be of such a character as to be decidedly advantageous.

Acme Corrugated Steel Mat.

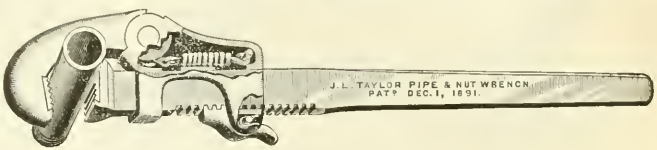
Cobin Mfg. Company, 107 Chambers street, New York, are putting the mat on the market as shown in the accompanying cut. The mat is made of corrugated steel strips held rigidly in a frame by means of rods, and also by projecting tips on each alternate strip, which engage in corresponding holes in the strips next to them. The manufacturers claim that the mats will keep their shape, as the tips make it impossible for the corrugated strips to move from the position in which they are originally placed. It is also claimed that the mats are clean, not accumulating deposits; that they are almost indestructible; that they are reversible; that they are safe, there being no danger of slipping; they will not flatten out, and that there are no points to catch or mutilate skirts or trousers. The mats are galvanized, and are recommended by the manufacturers for all places where mats are required. They are made regularly in eight sizes, from 16 x 24 to 36 x 72 inches. Extra sizes and unusual shapes are made to order.



Acme Corrugated Steel Mat.

The Taylor Pipe and Nut Wrench.

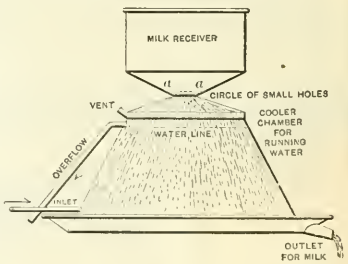
Hermann Boker & Co., 101 and 103 Duane street, New York, as sole agents for the manufacturers, are introducing the wrench illustrated herewith. The handle is made of forged steel, as are also the pivoted jaws; the sliding head of air-furnace refined malleable iron and the teeth plates of oil tempered tool steel. The pivoted head is held up to its work by a spiral spring in the sliding head, and the toothed thumb dog is held in place by a spiral spring on its pivot, as shown by illustration, portions of which are cut away. The teeth plates are detachably secured in dovetailed grooves, so that when desirable to renew the teeth plates, should they become worn or damaged, the old ones may be quickly driven out sideways with hammer and punch, and the new ones driven into position. A light blow of a hammer over each beveled corner locks them in position. The gripping principle is referred to as simple but effective, the wrench gripping its work independent of the spring. The point is made that no strain comes on either spring except that which is necessary to hold the parts in contact, and that the spring in the sliding head gives the self-adjusting feature to the wrench, enabling it to grip round, square, oval or any irregular shape with equal facility. It is stated that all parts of the wrench are interchangeable. The sliding jaw is held in any desired position by means of a multiple-toothed pawl or lock which engages with teeth formed upon the under side of the handle; the form of the teeth, together with the fact that several of them are always in use at the same time, gives additional strength. The pawl snaps into place by action of the spring when released, and when raised allows the sliding jaw to be instantly moved along to suit any pipe or object to be gripped. It is claimed that the wrench will grip a pipe and its connection with one setting; that it is quickly adjustable over a wide range by simply pressing the thumb dog, and that the wrench is so proportioned as to give the greatest strength with the least weight. They are finished all over, and are made in five sizes, to take from 0 to 2½-inch pipe.



The Taylor Pipe and Nut Wrench.

Improved Milk Aerator and Cooler.

The illustration presented herewith shows a milk aërator and cooler, for which an application for a patent has been made by H. Will Gazlay, Cortland, N. Y., who is manufacturing it, and claims that those in use are giving excellent results. It spreads the milk over a large surface for cooling, at the same time exposing it to the contact and influence of the air. The cooler chamber is circular, and the bottom forms a gutter around it with the use of but one seam. The receiver and cover to the cooler chamber are made solid together, so that there are but two parts. At the top of the cooler chamber is a vent, and just below the vent is an overflow pipe, while at the bottom is the inlet pipe, which is to be connected with running water, which may be cooled with ice if necessary. The water flows into the cooling chamber and rises and runs out of the overflow pipe. At a point in the bottom of the milk receiver, just above where it joins the cover, is a series of fine holes. When milk is poured into the receiver it runs out of these holes and spreads over the large flaring surface cooled by the running water, which cools the milk, while the air, it is said, has opportunity to carry off all odors, rendering the milk sweet and cool when it reaches the gutter, around which it flows to the outlet at the front. The ease with which it can be kept perfectly clean is referred to as a prominent feature.



Improved Milk Aerator and Cooler.

Good Luck Ice-Cream Freezer.

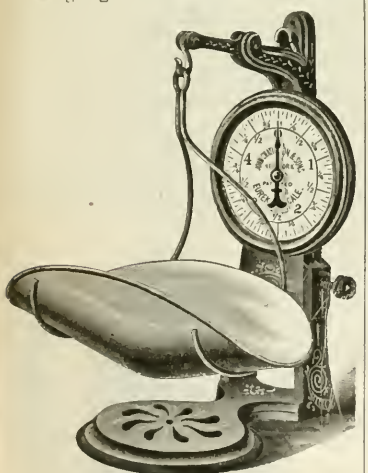
The accompanying cut illustrates a freezer put upon the market by Charles W. Packer, 20 North Fourth street, Philadelphia, Pa. The freezer is being made in response to a demand for a low priced freezer with covered gearing. It is remarked that in other respects it resembles the Standard Freezer manufactured by the same maker, and that it embodies all the

Good Luck Ice-Cream Freezer.

latest improvements, including the automatic double-acting vibratory scraper, which, it is stated, closely fits the can and thoroughly scrapes it during the process of freezing.

Eureka Tea and Spice Scale.

John Chatillon & Sons, 85–89 Cliff street, New York, are offering this scale, and recommend it for quick and accurate weighing. It is a modified form of their



Eureka Tea and Spice Scale.

butter scale of this pattern, a scoop being substituted for the marble plate. The thumb screw at the side is for keeping the scale in balance, and may also be used to equalize the tare of plate or package. The scale has a capacity of 5 pounds by ¼ ounces, and is made with brass scoop and brass bails, all nickeled; with brass scoop and brass bails, and with tinned scoop and iron bails.

Indurated Fiber Water Bucket

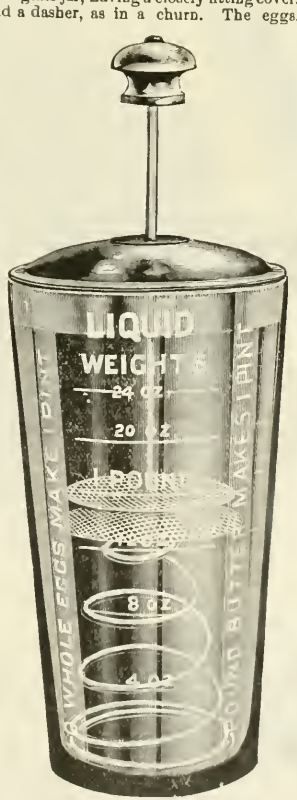
Cordley & Hayes, 172 Duane street, New York, are offering this article, as illustrated herewith. The inside diameter of the bucket is 12 inches, and it is 12 inches deep inside, having a capacity of 5 gallons. The faucet is nickel plated, the best, it is stated, the market can give, and the bucket is provided with a cover. The bucket is referred to as a substitute for a water cooler, cheaper, though fully

Indurated Fiber Water Bucket.

as good in every particular and very sensible. Covers are made with flush handle, as shown in the cut, also with elevated knob.

Lightning Dasher and Egg Beater.

Lightning Dasher Egg Beater Company, Orange and Erie streets, Toledo, Ohio, are introducing the above article as illustrated herewith. It consists of a graduated glass jar, having a closely fitting cover, and a dasher, as in a churn. The eggs,



Lightning Dasher and Egg Beater.

cream or other substance to be beaten is put into the jar, the lid pressed into place and the dasher pushed down by the hand of the operator, the coiled spring returning it again. This action, it is explained, forces the contents of the jar through the perforation of the double dasher, and that it will satisfactorily whip the most refractory eggs or cream in one minute. Attention is called to the fact that the beater has a tight fitting cover which prevents spattering, also of dirt or flies getting into the substance being beaten. The graduated jar is for use as a measure, the sides having marks by which weights or measures of liquids, flour, sugar, &c. may be determined. The manufacturers recommend it as an egg beater, cream whipper, lemonade and eggnog mixer, and as an ice cream freezer.

Waste in the Store and How to Avoid It.

SECOND ARTICLE.

By H. C. Wiseman.

The constant study of a subject, the main import of which is the caption above, will prevent many a man and many a firm from going to the wall. The writer, personally, has in mind a business acquired on a capital of $150,000, carried on for 11 years in a seemingly successful manner, the sales of which were enormous and based on a margin of profit that ordinarily would be more than safe—would be enriching. And yet that business literally leaked itself away. At the end of those years its stock was worth 40 cents. It sold finally under the hammer and did not realize 25 cents on the dollar on the original investment. It was full of leaks from cellar to garret, from office boy to president. They were never stopped, they grew, and those men to-day attribute every dollar of their loss to careless, criminal waste in the business. How to avoid it—be always on the lookout for it and know the remedy. Start at watching for small waste, and the habit will come of finding the large.

MATCHES, BROOMS, GAS, ETC.

In the store never set out a box of matches, put out a dozen or so. Set out the box and every man will take a handful. We've tried it and we now make one box go as far as a dozen formerly went. Buy a good broom, name a fair life for it, and when the old one is worn out serve the new one yourself. Tell your clerks: "There are a dozen brooms, use them," and with the most of them three will be used where one ought to answer.

Get every man in the house in the habit of turning down gas as soon as he is through with it. Two dollars a month saved for gas is a fair profit on $240 worth of goods sold in 12 months, or 10 per cent. on a $20 sale. Keep a nail box and use it—you throw them on the floor, why not in the box? Besides what we use again, we sell enough at 2 cents a pound to pay the broom account in a good sized retail store.

THE MATTER OF TYING.

Keep a twine reel and use that. Do not stop to untie knots—you cannot afford to lose the time—but cut off the knots, make a quick tie, give the reel a whirl, it is wound up and ready. Do not try to ball scrap twine,—the reel is better.

IRON SCRAPS, PAPER, ETC.

Save your iron scraps, it will surprise you to see the results of your hands alone

from bundles of iron coming in. And there is your paper account. I think I am safe in saying that with all the goods that come in pasteboard boxes, it is possible to save one half that account. The pasteboard boxes are the most convenient things in the world for sending out cut and wire and horse nails. Save the large pieces of pasteboard for every day special signs, and make a contract with some factory or foundry for all your good boxes, barrels and nail kegs. You will be surprised to see how much P. and D. you can credit to that account. While you are saving—save time, too. Buy a thousand or two cheap coin envelopes for brass headed tacks, screws, cupboard catches, brads, bed spring staples, &c., they take lots of time to wrap up, and that time is money.

SCALES.

ze on scales; have good
Do not economi. e that do not require
ones, and have thos w a pound. Your
down weight to sho what he buys, and
customer only expects eless clerks you

cannot possibly sell over here is noth-
what you bought as 100. uccessfully
ing that will rob a man so
as his scales.

DROWN A DOLLA[R] g for small
The habit of not chargi inal. You
odds and ends is almost crin. ds simply
cannot afford to give away goo or two,
because it is a screw, a screw-eye wire,
a handful of nails or 6 inches o[f] , and
They are all worth a penny or tw[o] ales
it takes but a few of these good-will ad-
to drown a dollar beyond recall. Frie[nd]
ship is one thing and business is another
if goods are marked right no man respects
you any more for cutting the price on
them, either asked or unasked. If you
do it, your clerks will. If you do not they
will not; and your example more than
all else will prevent their sacrificing you
in their little personal friendships. Other
leaks are the exposed samples of goods.
Sell them off, keep them fresh. Watch
the parts of goods. Keys and strikes for
locks, roses for knobs, nuts for bolts,
hoops for buckets, &c. If short, fill
them or fit them up; keep them as near
their original value as possible.

READY FOR SALE.

Cultivate the habit in the store of every one always having something to do, if only using the dust brush. Have goods ready to go out. Grass seed packages made up, nails out in 5, 10 and 20 pound lots. Your season's rubber hose fitted up with nozzles, bands and connections, and ready for sale. There are hours in a day saved in such work, and the biggest leak in any house is the time wasted by employees. These are but a few of the wastes and losses, and their remedies, that if closely watched, will certainly bring the right side of a merchant's balance sheet to the front at the end of the year.

The Spring-Back Window Cleaner.

Wm. Vogel & Bros., 37–47 South Ninth street, Brooklyn, N. Y., as selling agents for H. Clayton & Co., are introducing the above article, illustrated in Fig. 1. The cleaner is made of galvanized iron and rubber, with a spring or flexible back, an end view of which is given in Fig. 2. When the edge of the rubber becomes worn and rough, it is laid on a flat board and cut off close to the metallic strip with a sharp knife. The manufacturers claim that this operation can be repeated several times, and that the cleaner will not rust, rot, warp or crack. The cleaners are made in four sizes: 8, 10, 12 and 14 inches.

The Christy Improved Table Knife.

The Christy Knife Company, Fremont, Ohio, have added still another form of knife to their line, as illustrated herewith, and which they are offering under the name of the Christy Table Knife.

They refer to the new production as being made entirely of steel, both the blade and handle, the latter so secured to blade as to avoid any liability of its becoming loose.

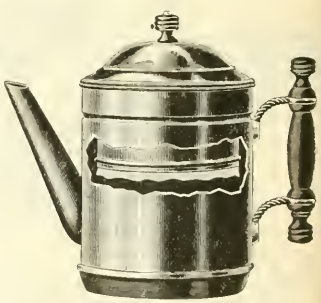
The Christy Improved Table Knife.

The knives are ground on one side only, making it more convenient to keep them sharp, and are heavily nickel plated, requiring no scouring to keep them clean and bright.

These knives, it is stated, are intended for use where it is desired to save the wear and tear of the more expensive silver-plated goods.

Puritan Coffee Pot.

The Bronson Supply Company, Cleveland, Ohio, and 72 Beekman street, New York, are bringing out a new coffee pot, as here shown, which will be known as the Puritan. The article is well made of heavy planished tin, or can be furnished nickeled. The enameled wooden handle is attached to the body of the pot by means of twisted wire securely fastened with stamped bosses to the sides of the vessel. The bottom is struck up in a die, and has a deflected edge, the bottom being joined to the body by a double-seaming machine, and soldered inside. One of the leading features of the coffee pot is the method now employed in making the filter. This consists of a metal rim having straight sides, with a bead at bottom in which is placed a circular wire spring for holding the filtering cloth. In many coffee pots the filtering facilities for various reasons have proved troublesome. As now arranged a piece of filtering cloth can be cut and put in place as often as desired by the most inexpert, and as the hot water poured on the pulverized coffee is compelled to go through the whole mass, the full strength is attained, there being no opportunity for it to escape at the sides. A bead in the coffee pot keeps the filter from going below a prescribed point. The general appearance of the utensil in make and finish is excellent. They are made in 2, 3, 4 and 5 pint sizes.

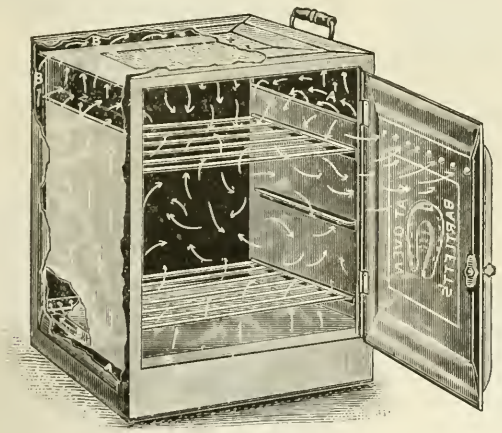


Puritan Coffee Pot, with Section Cut Away, Showing Filter.

STOVE TRADE NOTES.

The Bartlett Portable Gasoline Oven.

A portable oven intended for use in connection with gas, gasoline and other stoves has recently been brought to the attention of the trade by Russell, Bartlett & Kunz, Commercial and Market streets, St. Louis, Mo. The oven is constructed with two separate and distinct sets of flues. The first current of heat, we are informed, is admitted at the bottom of the oven, passes up the flue on either side of the oven marked A in the illustration and enters the baking chamber near the top of the inside lining, passing out through the openings in the top of the door. The heat currents are clearly indicated in the illustration, which represents an oven with the door open and portions of the side and top broken away. The second current of heat, we are told, is produced by a secret flue, marked B at the bottom of the oven, and connecting with the flue B at the back



The Bartlett Portable Gasoline Oven.

and top of the oven. It then passes down through the perforated plate C into the baking chamber and passes out through the same openings as those provided for the first set of flues. By this arrangement the manufacturers claim all articles baked are given a double current of heat over and across the top and also insured a thorough and efficient baking on the top and bottom. The oven is also provided with handles by means of which it can be readily moved about. In the directions which the manufacturers give for using this oven the operator is cautioned to have the bottom plate forming the secret flue to rest on the bottom and against the back of the oven. The oven, it is claimed, should be placed over the burner so that all the blaze will be admitted into the opening at the bottom. The oven should be well heated before placing articles within, the time for heating varying from six to ten minutes.

Diamond Extension Stove Back.

The Adams Company, Dubuque, Iowa, are introducing to the trade the extension stove back illustrated in the accompanying engravings. The construction is such that

Diamond Extension Stove Back.—Fig. 1. Stove Back Closed.

no bolts are required, the extended part being fitted in dovetails and driven together in oil. When the oil burns off, the makers say the back becomes nearly rigid. The flange that fits along the oven plate is on a straight line and is said to make an ash tight joint. The dovetail referred to is above the fire, where it is less liable to become heated and will not, the makers state, warp or become loose. Fig. 1 of the engravings shows the Diamond stove back closed, while Fig. 2 represents it in extended position. It is said that one size adjusts in width from 4½ to 7 inches and in length from 15 to 20 inches. The manufacturers refer to the ease with which this stove back is fitted and state that a small hammer is all that is necessary to adjust it.

Fig. 2.—Stove Back Extended.

Women's Ideas on Gas Stoves.

BY O. B. SERVER.

Very pertinent facts and worthy of careful observation were gleaned from chats with the sellers of gas stoves at various places in the East during a stroll among them. It appears that what has been sometimes called by the trade "Hot Plates," in speaking of the one or more burners arranged on a cast or wrought frame, which can be set on anything of convenient hight and to which the oven is an independent portable affair, has now secured a new name through the inquiries of the ladies. "Table Stove," and not gas range, as the larger and more complete affairs are designated by them, is what is now daily inquired for and examined. Another interesting hint to the makers of table stoves was that those sold best and were most popular which had the burners farthest apart, so that the oven did not encroach on the space of the next burner and interfere with a tea kettle or other cooking utensil. Stoves which had been previously very popular and sold freely were hard to move since the appearance of stoves having a very appreciable and marked increase of space between the burners. These same all-influential critics seemed to favor a stove smoothly cast in plain iron in preference to those that were coated with a dull nickel with very little polished surface, but if heavily nickeled, clean and white, with a generous space of polished surface, there was no objection to nickel plating.

THE JACKSON MFG. COMPANY is the name of a concern recently organized at Hammond, Ind., with a capital stock of $150,000. The directors include Charles A. Van Anden, W. H. Gostlin, George H. Helberg, James McCoskrie and M. M. Towle. The officers are Charles A. Van Anden, president; W. H. Gostlin, vice-president; M. M. Towle, treasurer; James McCoskrie, secretary, and Francis Jackson, general manager. We understand it is the intention of the company to produce a superior grade of stoves which, while proving entirely satisfactory in operation, will be very economical in the consumption of fuel.

Heating and Cooking by Electricity.

Among the latest candidates for public favor in the line of appliances for heating and cooking purposes is an electrical device at present in extensive use in Ottawa, Canada, and which was designed by T. Ahearn of the firm of Ahearn & Soper of the place named. The device is being introduced into the United States by the Railway Equipment Company, Pullman Building, Chicago, Ill., who have completed satisfactory arrangements for the

According to the statements of Mr. Ahearn, this stove with 6 ampères of current is equal in heat giving power to an ordinary coal stove. It is stated that the stove is wound with wire in order to permit of the use of a constant current throughout the day, so as to require no attention on the part of the conductor. Another type of heater which has recently been brought out is represented in Fig. 2 of the illustrations. This, it will be observed, is oval in shape, and four of them will take the same amount of current that is necessary for the cylindrical heater shown in the

which would be apt to lead to the rapid deterioration of the wire. The winding of the inner or central tube is also calculated to concentrate the heat at that point, while leaving the outer casing comparatively cool.

The application of electricity to cooking purposes in connection with the Ahearn appliances is shown in Figs. 4 and 5 of the illustrations. The former represents a plan view of an electric bake oven, while Fig. 5 represents a vertical section through it. The plan view shows the position of three electric heaters with which, it is claimed,

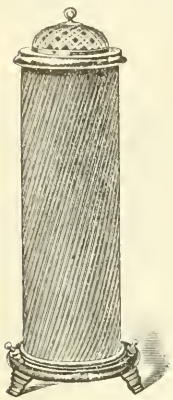


Fig. 1.—Cylindrical Car Heater.

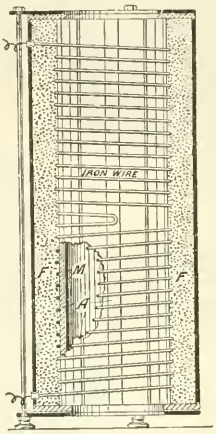

Fig. 3.—Sectional View, Showing Construction of the Ahearn Electric Heater.

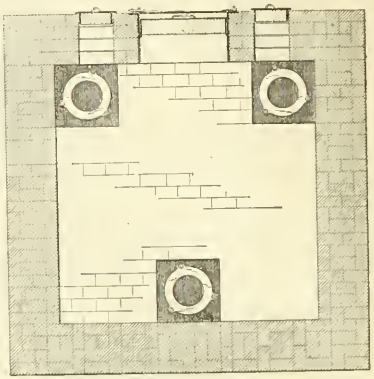

Fig. 4.—Plan View of Electric Bake Oven, Showing Position of Heaters.

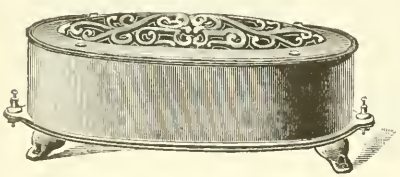

Fig. 2.—Oval-Shaped Car Heater.

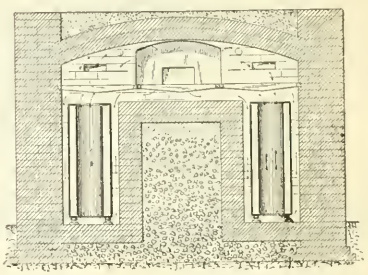

Fig. 5.—Vertical Section through Bake Oven.

HEATING AND COOKING BY ELECTRICITY.

purpose with the firm above mentioned. One form of the heater intended for use in car service is shown in Fig. 1 of the cuts, which represents a stove, as it may be called, cylindrical in shape and measuring 20 inches in hight by 11 inches outside and 7 inches inside diameters. It is practically two iron tubes, one being placed within the other. The inner tube is wound with iron wire, and the space between the inner and outer tubes filled with whiting, powdered fire-clay or sand, as the case may be. The stove, as will be noticed from the engraving, is placed a short distance from the floor, allowing the cold air to be drawn under it and into the central opening or tube, through which it rises, gradually increasing in temperature and creating a thorough circulation of the air.

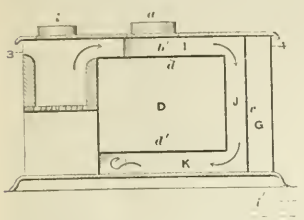
previous figure. A better idea of the manner in which the inner cylinder of the heater is wound may be gathered from an inspection of Fig. 3 The winding of the iron wire is said to be done in such a way as to counteract self-induction and constant flashing of the switch. The direction of the winding is reversed at the center of the coil, as shown in the engraving.

Another point to be noted in this connection, is that the winding wire does not cover the entire surface of the inner tube but terminates a short distance from the top. The inventor gives as a reason for this, that, as the hottest portion of the heater is at the top there would be at that point, if the winding was continued clear up, too great a concentration of the heat,

a baking temperature of 400° F. may be maintained. The size of each of the heaters used in connection with the bake oven is 29 inches high and with inside and outside diameters of 7 and 11 inches respectively. Two of the heaters take 20 ampères and the third 19 ampères at 50 volts. This bake oven was constructed as a portion of the recent exhibit at the grounds of the Central Canada Exhibition of electric heating apparatus. It is claimed that only two heaters of the dimensions given are necessary for use in the oven under ordinary circumstances, but the third was put in this exhibition oven in order to compensate for the frequent opening and shutting of doors rendered necessary by the large amount of food which was baked for sale to curious visitors.

Combination Cook Stove and Heater.

A rather novel form of stove construction by which the device can be used for cooking purposes, while, at the same time, the hot air may be employed for heating an apartment other than that in which the stove or range is located, has recently been brought to the attention of the trade by Franklin L. Sheppard of the house of Isaac A. Sheppard & Co., Philadelphia, Pa. The illustrations which are presented herewith will help to render clear the general construction employed. Fig. 1 is a vertical section through the fire pot and oven, while Fig. 2 is a plan view taken on the line 3 4 of Fig. 1. One of the objects of this form of construction is to utilize the waste heat in connection with cooking



Combination Cook Stove and Heater.—Fig. 1.—Vertical Longitudinal Section.

operations. Above the oven of the stove are two flues represented by 1 and 1 and separated by the plate marked *b*. These flues connect respectively with the descending passage J and the ascending flue J at the end of the oven. These two flues, in turn, are also separated by a partition plate, but communicate underneath the oven with two other flues, one of which is represented by K. These flues are also separated a portion of their distance by a partition, but communicate with each other at the ends nearest the fire box, so that the products of combustion follow the course indicated by the arrows and es-

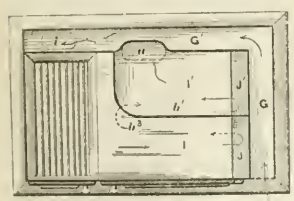


Fig 2.—Plan View Taken on Line 3 4 of Fig. 1.

cape at the pipe outlet marked *a* in the engravings. The construction is such that the greater portion of the heat strikes the plate marked *c*, which with one of the end plates of the oven, inclose the ascending and descending flues J and J' already referred to. This plate, *c*, becomes very hot, and in order to utilize the heat to advantage, and also the heat radiated from the back plate of the stove, a hot-air flue, G, is formed as shown. The air is admitted to the flue through a perforated plate at the front of the stove, clearly indicated in Fig. 2 of the illustrations, and after passing through the flues G and G' is discharged through the opening *i* into a pipe which carries it to the room to be heated. By this means, it is claimed, a constant current of air highly heated in its passage is carried to the room above that in which the stove is located, and a thorough circulation created. In some instances the cold air may by taken from the outside of the room in which the stove is placed, or from an adjoining apartment, so that the fumes of cooking would not be fed to the room to be heated. The flue for admitting the air is indicated by the dotted lines *i'* of Fig. 1. This device, we understand, is being employed by the company in connection with their line of Fidelity ranges.

Indiana Stove Works.

Among the first to favor us with a catalogue of stoves, ranges and heaters for the season 1893-94 is the Indiana Stove Works, with foundry, warehouse and sample rooms located at Seventeenth avenue, Indiana and Illinois streets, Evansville, Ind. In presenting the volume to the trade the company state that they have little comment to make. Their Darling line of stoves and ranges has met with very gratifying success, and as the best material and most skilled workmen are employed in producing them, it is confidently expected that their popularity will show a steady increase. The opening pages of the catalogue are devoted to miscellaneous matters, including telegraphic code, statement of terms, cost of repairs, reference to breakages and freight overcharges on stoves and castings, directions for setting up and operating stoves and an alphabetical index. The first construction to which attention is invited is the Grand Darling, a wood range which is made in two series, one having four and the other six boiler holes. The ornamentation is neat and effective and the constructive features embodied are of the latest type. These goods are made in a number of styles and in sufficient variety to meet the wants of the trade. The Queen Darling is a neat wood cook, first class in every respect and possessing, among other features, detachable enameled reservoir, patent door kicker, drop hearth slide, cemented oven plate, patent damper, which can be easily taken out and replaced without dismounting the stove, and cast door handles. The Darling A is shown in Series A and B and is offered the trade in numerous styles and sizes. The New Olive is a four-hole cook for burning wood, and is fitted with the latest improvements. Under the name Darling the company also manufacture a steel range, intended for hard coal, soft coal or wood. It is built up of heavy steel plate, with oven doors, hinges, latches, &c., of malleable iron. The grates employed are double acting, revolving from their center, the oscillating motion sifting the ashes and crushing the clinkers that come in contact with it and dumping them into the ash pan beneath. The fire box being oval in form, protects the fire lining so that the arch, it is stated, would have to be broken before the lining would warp or crack. In connection with the illustrations of this range are given weights, code words, list prices and directions for operating. Among the cast iron ranges the prominent construction is the Darling, with six holes, and adapted for burning coal. This is made in four sizes, and the usual modifications. The coal and wood cook stoves number several varieties of the Darling family, and are of modern construction. The heating stoves fill the latter portion of the catalogue, and are represented by the Darling Oak, a neat, substantial oak, made in three sizes; the Rival Oak, a medium-priced heater, made in five sizes; the Burr Oak, a low-priced heater; the Round Darling, a heavy cannon stove, shown with and without Russia iron drum; the Sloss, another cannon; the Home Darling, a very pretty cottage parlor, which the company have recently brought out; the Cottage Darling, another recent addition to the company's assortment, and adapted for burning coal or wood; the Daisy, the Longwood, the Eclipse and the New Darling, the latter being an attractive Todd. A list of hollow ware and sundries completes the catalogue.

School for Molders' Apprentices.

About three years ago Valentine Geiselhart, foreman of the foundry of James McKinney & Son of Albany, N. Y., started a trade school in that city for molders' apprentices. His motive was solely a philanthropic one, for he had taken a great interest in the boys and was anxious to have them become the best of molders. His ambition in the line of a trade school was a comprehensive one, though he decided to start in a modest and economical way. A number of the boys in various local iron-molding shops became interested, and there was every promise of a large school being established. A room was hired and the school was organized. But the molders' labor organization did not like this. They looked upon it, not from a correct and unprejudiced standpoint, but as a rival organization. It was not to be a labor organization in any sense of the word; but this explanation was not accepted by the union. They frowned upon the project, and practically vetoed it. This was throwing cold water on Mr. Geiselhart's efforts, and he felt it keenly. Through influence a large number of the apprentices were withdrawn from his meetings, and the result was that the apprentices who remained were unable to hire quarters and establish such a school as Mr. Geiselhart had ultimately hoped would be produced.

Undaunted, however, the friend of the boys continued in his efforts. The room was given up and the meetings discontinued for a time. But Mr. Geiselhart so arranged it that the boys who desired instruction might meet at his own home. A few of the apprentices accepted his kind invitation, and since that time have gathered there Monday nights. Foreman Geiselhart continues the school at his own expense and the boys have made excellent and rapid progress. He takes for his topics, especially, pieces of difficult work which are being done in the molding shop, invites the apprentices to ask any questions they wish regarding them and explains away the difficulties. The consequence is that the apprentices under Mr. Geiselhart are becoming very skillful. In fact, many of them are equal to the best molders, if not better, in many particulars. They learn readily, and, profiting by their lessons, grasp ideas which they never would obtain in any other way. All this is done by their kind instructor gratuitously and gladly. After the school he entertains them with refreshments and gives them free access to all his books and facilities for instruction. When there is occasionally a holiday the boys go on a trip with their teacher to large plants in the vicinity, where they may observe works that will interest and instruct them. In

this way they have visited the large iron and steel works in Troy and other places. A number of boys have joined the class recently, and the school, though not very large, is in a flourishing condition. The scholars will make the finest kind of molders, and Mr. Geiselhart deserves great credit for his work.

The Fuller-Warren Company,
